There was launched from the shipbuilding yard of Messrs. Robert Stephenson and Co., Hebburn-on-Tyne, on February 27th, an iron towing hopper barge, built to the order of the South Shields Corporation. This barge has been specially designed by C. H. Tate, naval architect, Newcastle-on-Tyne, for the removal of the town refuse of South Shields. The hopper is of large capacity, to enable her to take to sea 350 tons of this refuse. She is fitted up with powerful winches for hoisting the doors, and a special arrangement of slipping gear for letting the doors fall. We may mention that this type of craft is becoming very popular with other corporations situated near the sea-board. South Shields is following the lead of the Gateshead Corporation, who in this district were the pioneers of this mode of disposal, and who had a similar craft built some four years ago which has proved a great success, this craft being of similar design to the one just launched: the quantity of refuse per annum disposed of by them in this manner amounts to about 50,000 tons. We understand that other corporations are now adopting the same principle, which no doubt will become quite general, the expense as compared with the destructors being enormously to the advantage of the disposal of refuse by the barge at sea. Before the launch the vessel was inspected by the Committee of the South Shields Corporation, including Alderman Redhead—ex-mayor—Aldermen Eltringham, Rennoldson, and Lawson, who expressed themselves highly satisfied with the workmanship and design. On leaving the ways the vessel was named the Shadwell.

A few days ago the s.s. Greylands, a fine steel screw steamer, built by Messrs. William Gray and Co. for Messrs. Robert Hardy and Co., of West Hartlepool, left that port for her trial trip. The vessel has been built to Lloyd's highest class, and is of the following dimensions:—Length over all, 324ft.; breadth, 44ft.; and depth, 23ft. 3in.; deadweight over 4100 tons on a draught of about 19ft. The deck erections consist of a poop, bridge over machinery space, and topgallant forecastle. A handsome saloon and cabins for officers, &c., are fitted in the poop, the engineers' rooms are in the bridge, and the crew's accommodation forward. The hull is built on the web frame system, with a cellular double bottom, large hatchways, powerful steam winches, steam steering gear amidships, hand screw gear aft, patent donkey boiler, patent direct steam windlass, boats on beams overhead, shifting boards throughout, stockless anchors, two masts with schooner rig, and a complete outfit for a first-class cargo vessel. The engines are of the Central Marine Engine Works' well-known triple expansion type, having cylinders 23in., 36in., and 62in. in diameter, with a piston stroke of 39in., and are supplied with steam by two large boilers working at a pressure of 160 lb. per square inch. After some hours' manœuvring in the bay the vessel was brought to off the headland to receive a party of inspecting engineers and visitors, amongst whom were Mr. Robert Hardy, managing owner; Mr. Gates, inspecting engineer for the company; Mr. Matt. Harrison, Mr. C. A. Forslind, Mr. Chalton, Mr. Jacob Hessler, Mr. Jos. Merryweather, Captain Bacon, and Captains T. and W. Watson, visitors; Captain Murrell, on behalf of the shipbuilders; and Mr. Lindsay, representing the engine builders. The engines were now put full speed ahead with the log overboard, when it was found that she averaged a speed of 11 knots. The engines ran with perfect smoothness and without a hitch, the trial being in every respect a highly satisfactory one. The Greylands proceeded direct to Tyne Dock, where her visitors were put ashore, and the vessel will load for Genoa.

THE INSTITUTION OF CIVIL ENGINEERS.

LITTORAL DRIFT: IN RELATION TO RIVER OUTFALLS AND TO HARBOUR ENTRANCES.

At the ordinary meeting on Tuesday, March 3rd, Mr. W. H. Preece, C.B., vice-president, in the chair, the paper read was on "Littoral Drift: in relation to River Outfalls and to Harbour Entrances," by Mr. W. H. Wheeler, M.Inst.C.E.

The author pointed out that the success or failure of works projected for the improvement of navigation on coasts subject to littoral drift depended on a correct application of the laws which governed the movement of sand, shingle, and alluvial matter. It was shown that the supply of drift was limited and within control; and that the vast beds of sand with which the sea-bed was covered, and the deposits of sand and shingle found on many parts of the coast were due to causes which occurred in remote ages under entirely different conditions to those now prevailing. Instances were given to prove the impossibility of these accumulations having been formed by existing agencies. The drift which now travelled along the coast and the movable sand beds were shown to be due to the erosion of the cliffs, and as coming from the waste of the land and not from the sea bed.

It was stated that the generally accepted theory, that the travel of drift along a coast was due to and was in the direction of the prevailing wind, was contrary to fact. In England the prevailing winds were from the south-west; whereas the travel of drift on the east coast was southwards, on the south coast from the westwards, and on the west coast northwards, in each case being in the same direction as the flood tide. Round bays and estuaries, frequently within a very limited area, the travel was in three or four different directions. Numerous examples of drift in England and other countries were given, and in every case the continuous and regular travel was in the direction of the flood tide.

The author had been unable to find a single instance where the regular and continuous travel of drift along a coast was in the opposite direction to that of the flood tide. Storms which blew in an opposite direction to the flood tide arrested the progress of the drift, and even for a time caused it to travel against it; but these were only occasional, and on their cessation the normal direction of travel was resumed. While winds and waves were the agents which operated in eroding cliffs and producing the supply of drift, the continuous progressive movement of sand and shingle along the sea coast was caused by the wave action of the flood tide, which was increased when the wind blew in the same direction as the flood tide. The action of the flood tide making along a coast did not consist in a gradual swelling or raising of the water, but a series of small waves were given off from the main tidal wave, which broke on the shore in an oblique direction, the crest running up and partly lifting and partly pushing the stones forward and onward to the height reached by the wave, and consequently several feet above high-water mark. The retiring wave descended down the line of quickest descent, or that normal to the beach, and carried with it the greater portion of the material lifted up, leaving the remainder behind. The crest of the wave being wedge-shaped, the thin film of water at the top, as it retired, was incapable of carrying back the larger stones driven up by the momentum of the body of water behind, and these were left near the top of the bank. The number of wavelets varied between ten and twenty per minute, making, with the smaller number, 7200 impulses on the flood tide in the course of a day, and consequently capable of elevating and transporting a large quantity of material in the course of a year. The weight of the stones moved by these tidal shore waves in calm weather varied between a fraction of an ounce and 5 lb. or 6 lb. when out of the water. The shore waves of the ebb tide struck the beach at the same angle of those of the flood, and the tendency was therefore to prevent any retrogressive movement.

With regard to alluvial matter in estuaries, it was shown that this was derived from detritus brought down by rivers, and did not come from the sea, and that it was not supplied from the waste of clay or chalk cliffs along the sea coast. The only current along the coasts of England which could transport material in suspension was that due to the tidal wave, which travelled each way for about six hours at the rate of between 2 knots and 2½ knots. The greatest distance material could be carried in one direction in suspension was therefore 15 miles, and, as the material eroded from the cliffs was not reached until some time after the tide had been running, it would be carried a shorter distance toward the mouth of an estuary on the flood than away from it on the ebb, and with each tide would become more and more diffused over a great volume of water. It was contrary to all known laws of tidal action in rivers for material in suspension to be carried upwards for any great distance above the mouth of a river or estuary. The tidal wave propagated up a river created only an oscillating current, and the same quantity of tidal water which went up returned on the ebb, with the addition of the current produced by the fresh water; the tendency of movement was therefore downward, and not upward. As a further proof that solid matter in suspension could not be carried up a tidal river for any great distance, the salt from the sea, which was far more readily diffused than solid matter, penetrated only the lower reaches, the water entirely losing its saline properties as the tidal current progressed upwards.

Except in very heavy gales, submerged sand beds were not subject to alteration. So long as the natural conditions remained unaltered and the set of the tides was not interfered with, the equilibrium originally established between the several contending forces would remain. The effect of wave-action diminished rapidly as the depth increased, and while this action was only occasional, the tidal currents were continuous. When a channel was sufficiently deep to resist the surface action of the winds, the tidal currents would maintain it. Numerous examples of the permanency of natural channels passing through sand beds were given, and it was pointed out that the improvements which had been effected in dredging by means of sand pumps rendered it practicable to permanently deepen the channels of the outfalls of rivers in sandy estuaries and the estuaries to harbours. The results obtained by dredging in the harbour of New York, on the Mersey Bar, across the Stroombank at Ostend, and across the Charpentier Bank at the mouth of the Loire, were sufficient to show that it was practicable to improve the approach to harbours on sandy coasts by suction-dredging without the aid of training walls, and at considerably less cost.

Applying these facts, the following principles were deduced as essential in the construction of harbours on shingly or sandy coasts:—(1) That piers running out from the coast should be so projected as not to derange the main set of the tidal stream, and be so designed as not to cause an eddy-current at the entrance to the harbour; (2) that the entrance to a harbour should be sufficiently large to prevent any strong set into it on the rising tide, and to allow of its being filled with a current of lower velocity than that of the flood tide past the front of the entrance; (3) that the piers should project out from the coast into water of sufficient depth to be free from the action of littoral drift, and beyond the local influence of matter in suspension derived from the waste of cliffs or detritus brought down by rivers. Several examples of harbours were given which had been successful or otherwise, dependent upon compliance with these principles in their construction.

Municipal Engineer, Singapore.—Mr. Sam Tomlinson, Water Engineer, Bombay, has been appointed to the post.

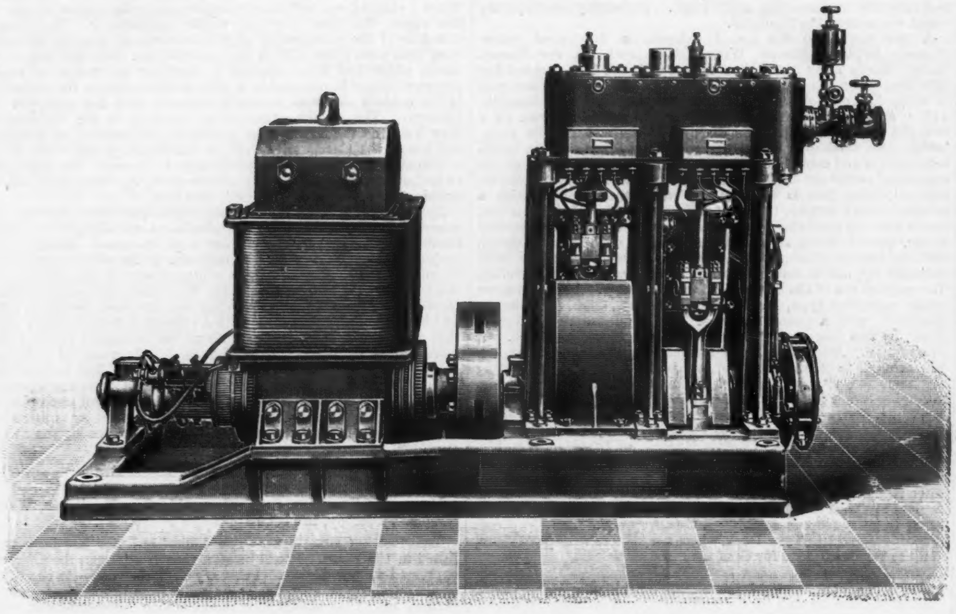
Traction on Highways.—The following letter has been published in the *Times*. It will be seen that it endorses the views we expressed in our issue of February 28th:—"Sir,—As one of an agricultural community, five or six miles from the nearest railway station, may I lay before your readers, with little comment, some long-considered ideas on the above subject? I hold that a modification of the new automotor car, by construction or adaptation of existing types of vehicles, would almost entirely obviate such a doubtful benefit as a light railway—for the following reasons:—(1) The automotor car has its roads ready, so that any district may take up the system at once. (2) As to the expense, £1500 per mile is stated to be the cost of construction of light railways. This should supply ten cars per mile, probably twice as many as required. In case of failure, too, but little would be wasted. (3) Transhipment of goods twice saved at least, and every chance afforded the producer of getting into direct communication with the consumer. Moreover, the important detail of door-to-door collection of goods can be easily carried out, thus reducing the farmer's expense generally. (4) Private enterprise, so frequently better than Government, could so easily and quickly assist this system. In conclusion, I would state that this system appears to me—perhaps too like an enthusiastic beginner—in its various adaptations to be capable of becoming England's salvation.—Ombersley."

Proposed Canal from Lockfyne to Crinan.—On this subject the *Glasgow Weekly Herald* says:—"We understand that a number of influential gentlemen in Glasgow and the West Highlands are at present contemplating the formation of a ship canal parallel with the present Crinan Canal for the accommodation of vessels of 1000 tons burden, and some progress has already been made in the promotion of the scheme. Some time ago an eminent firm of engineers took the matter on hand, and they have now prepared and submitted plans of a comprehensive undertaking which, if carried out, would prove of immense value to shipping and to the district. According to the plans it is intended to dredge a waterway along the shore from Ardrishaig to Lochgilphead, where it is proposed to begin the canal proper in the neighbourhood of the Corran, and form it in as straight a line as possible to Barnakill, from whence a channel will again be dredged to old Crinan. The scheme, which is estimated to cost about half a million sterling, also includes the formation of a large storage reservoir at Crinan, and the reclamation of the extensive ebb at Lochgilphead, with the construction of wharves and other accommodation for vessels at Lochgilphead, Bellanoch, and Crinan. It is anticipated that, in addition to the smaller craft which use the present Crinan Canal—now 100 years old—vessels trading between Glasgow, Liverpool, and the north-west coast of Europe, the large West Highland steamers, and all classes of yachts, would take advantage of the new route, which would undoubtedly be a shorter and safer one in all weathers."

The Electric Lighting of Islington.—The public supply of electricity is being taken up to an increasing extent by municipal authorities, and Islington, the largest parish in the United Kingdom, has not been slow in following the lead of St. Pancras and so many provincial towns. The new station for the supply of electricity is stuated in Eden-grove, Holloway-road, N., and it was formally opened on Wednesday last by the Lord Mayor, accompanied by the Lady Mayoress. There was a very large attendance. The Rev. Dr. Barlow, J.P., vicar of the parish and chairman of the Vestry, along with the members of the Electric Lighting Committee, received the Lord Mayor's party. Others who were present were Sir Albert Rollit, M.P., Mr. G. C. T. Bartley, Mr. Lough, M.P., and Mr. B. L. Cohen, M.P. The Vestry-Clerk, Mr. W. F. Dewey, read an address in which a description of the undertaking was given. The cost of the whole work may be put down at about £81,354. The architect has been Mr. A. Hessell Tiltman, F.R.I.B.A., the resident engineer is Mr. Albert Gay, M.I.M.E., and the contractors Messrs. Adamson and Co. The system is that of high tension alternate current with transformers. The area now supplied with current is the road which begins at the Angel, Islington, and leads to Finsbury Park Station. The station itself has been built so as to allow of considerable enlargement, and at present it consists of an engine-room, in which are installed four engines and four dynamos capable of supplying the equivalent of 15,000 lamps of 8-candle power; a boiler-house containing four Lancashire boilers and two Babcock and Wilcox boilers, and also workshops and offices. Within the area over which the Vestry has jurisdiction, fourteen miles of pipes and twenty-five miles of cable have been laid, and there are now in use ninety-eight arc lamps each of 2500-candle power for public lighting. After the party had inspected the works there were various votes of thanks, and the Lord Mayor spoke, commending the public spirit of the parish. Mr. Gay, the electrical engineer, stated that already there were applications for current for private lighting which far exceeded the amount which could at present be devoted to this purpose. The Lord Mayor then turned a switch, which set the whole of the machinery in motion, and lighted up all the arc lamps in the streets. We may state that the work was authorised by Provisional Order, and this was confirmed by Act of Parliament in 1893. In the evening the Electric Lighting Committee celebrated the event by a banquet at the Holborn Restaurant, where Mr. Samuel Lambert presided. The toast of the evening, "Success to the Electric Lighting of Islington," was given by Sir Albert Rollit in an eloquent speech, and acknowledged by Mr. T. W. Vine. An address and a purse of gold were presented to Mr. Lambert in acknowledgment of his services as chairman of the Electric Lighting Committee; and the work of the architect, electrical engineer, and contractors was also acknowledged. We hope very shortly to put our readers in full possession of details of this new station.

COMPOUND ENGINE AND DYNAMO

MESSRS. J. P. HALL AND CO., OLDHAM, ENGINEERS



COMBINED COMPOUND ENGINE AND DYNAMO.

MESSRS. J. P. HALL AND Co., of the Black-riding Ironworks, Werneth, Oldham, who make a speciality of electric lighting plant, particularly for steamship purposes, have recently designed an improved arrangement for combining compound engines and dynamos upon the same bed in a remarkably compact form. The illustration we give is taken from a photograph of their latest design of this kind, and shows clearly the general construction and arrangement. The engines are constructed to give 25 indicated horse-power at 300 revolutions per minute, with 120 lb. steam pressure, when exhausting into the atmosphere, and the cylinders, which are provided with spring relief valves as well as the ordinary drains, are 5in. and 8½in. diameter, by 7in. stroke, with the low-pressure valve between. All the moving parts are made as light as is consistent with the required strength, the pistons, which are dome-shaped, being of steel, and the crossheads of cast steel, lined with magnolia metal, whilst the connecting-rods, which are of the ordinary marine type, are of forged steel, lined with phosphor bronze. Each line of moving parts is separately balanced with weights forged on the crank shafts, and the cranks are placed on opposite centres, so that the engines may be balanced and run without vibration.

The engines are fitted with the firm's patent automatic expansion type of governors, of which an illustrated notice appeared in these columns some time ago, and by which the stroke of the excentric is varied from 2in. to 1in. These governors are very quick to act with any small variation in load, the engines governing to within 2 per cent. between no load and full load. The engine beds are, as will be seen from illustration, made with an extension for carrying the dynamo, the main bearings being cast on and all bored in position, and bushed with phosphor bronze, the bush at the fly-wheel end being double length, as it has to carry the weight of the armature and fly-wheel.

The dynamo itself is of the ordinary slow-speed type made by the firm, with drum bar armatures, and developes 120 ampères at 100 volts, with a maximum temperature rise of 60 deg. Fah., after six hours' run with full load, whilst the magnet coils are wound on sheet iron bobbins, with teak flanges for carrying the terminals. The lubrication throughout is continuous, ample provision being made for catching the waste oil.

THE PROPOSED LANCASHIRE PLATEWAY.

A SINGULAR scheme for obtaining cheaper rates of carriage for goods is being talked of in Lancashire, not for the first time. Its title is somewhat archaic, being nothing more or less than "The Lancashire Plateway Scheme." In principle it may be described as a system of goods tramways of a very comprehensive kind, and a line from Liverpool to Manchester is recommended as the best to make a start with. Long plates of iron or steel, with a flange on the inside to keep the wagons on the line, would be laid down on a substructure sufficiently strong to carry light locomotives. Very slow speeds would be run, but the essential point of the thing is that the wagons could be taken on by horses straight from the plateway terminus to the mill or works or wharf they were intended for. By these means, enormous and costly goods stations, and the expense of collection and delivery, with the double handling they imply, are to be done away with. The wagons or "lurries" would have loose wheels on fixed axles, and be in general, no doubt, much like those sometimes used on the common roads in connection with traction engines. In fact, the system would be a compromise between railway transport and steam road traction, with a little of the light railway element thrown in. The projectors of this somewhat crude idea consider that the crying evil of modern goods rates is the terminal charges, and that if these can be largely reduced a commercial millennium will infallibly result. The plateway is especially designed to grapple with this subject, and is considered to afford a better solution of the difficulty than canals or anything else yet thought of can possibly do. Part of the superior economy over railways is expected to arise from the slow speeds, which certainly means less wear and tear, and part from the superior lightness of the wagons in proportion to their paying load. The saving of time in loading and unloading at the termini will, it is thought, quite make up for the low rate of speed on the plateway itself, and with the very short distances of South Lancashire this will not, perhaps, greatly matter. An average rate of about one penny per ton per mile, with an extra charge of ninepence per ton at each end to cover, we presume, the cost of horse transit when the company provides it, is talked of as being probably about the expense to the trader of getting goods from Liverpool to Manchester, or *vice versâ*. The Manchester Ship Canal is not considered likely, by the supporters of the plateway, to effect any considerable or permanent reduction of rates in the district it traverses, and so the system of transport we have been discussing has been brought forward once more. It was more seriously discussed some fifteen years ago, before the canal was thought of, than we believe it will be now. Not only are the railway rates lower than they were then, but the complete financial failure of the canal for the present is likely to make Lancashire folks very chary indeed of embarking in any scheme of improved transit which has been so insufficiently thought out as this new one. Neither mechanically nor economically does it appear to afford much chance of relief from a considerably exaggerated evil, and, after all, it should be considered that the railways have largely made Lancashire what it is, and that they have decidedly a moral right to be allowed to live in it.

HORSELESS CARRIAGE NOTES.

WE hear from our American correspondent that the management of *The Cosmopolitan*, a monthly magazine, is offering £600 in premiums to be awarded to horseless carriages presenting the greatest number of points of excellence, as exhibited in a trial trip to be made on May 30th. This trip will be from the City Hall Park, in New York, to Irvington and back, a total distance of 52 miles. The award will be made upon the following points, the maximum aggregate being 100:—Speed, 50; simplicity and durability of construction, 25; ease in operating, and safety, 15; cost, 10. The route will be along Broadway, through Central Park and over the Washington Bridge, thence along the main road to Yonkers, where the course will include five miles of asphalt paving, and then on to Irvington, on the Hudson River, 26 miles. There is a good road for the entire distance.

A GASOLINE carriage built after the style of a park phæton, but having a complicated and cumbersome mechanism, was built and operated by Mr. Harris, at Baltimore, U.S.A., in 1891. A large gasoline tank was mounted on the front of the carriage, and the motor and controlling apparatus were placed beneath the body. The carriage had accommodation for fifteen persons, and was very heavy.

A NEW style of wheel for horseless carriages is being used by Mr. J. B. West, of Rochester, U.S.A., a thin web plate of steel replacing the usual arrangement of spokes. This is used on a single-seat carriage weighing 600 lb., and fitted with a gasoline motor of the same weight.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

LARGE attendance on 'Change. Steam coal in good demand, and prices steady. House coal shipments continue without change in demand or price. Tin-plates show no improvement in demand.

Prices of manufactured iron and steel advancing. Coal: best steam, 8s. 3d. to 8s. 6d.; seconds, 8s.; best house coal, 10s. 3d. to 10s. 6d.; dock screenings, 5s.; colliery small, 4s. 6d. to 4s. 9d.; smith's coal, 6s. 9d. Patent fuel, 10s. 3d. Pig iron: Scotch warrants, 47s. 8d.; hematite warrants, 49s. 4d., f.o.b. Cumberland; Middlesbrough No. 3, 38s. 10d., prompt; Middlesbrough hematite, 46s. 7d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails, heavy sections, £4 15s.; light, £5, f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 5s.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s. 1½d.; Siemens coke finish, 9s. 4½d.; ternes, per double box, 28 by 20 C., 21s. to 22s. Pitwood, 15s. 6d. London Exchange Telegram:—Copper, £45 18s. 6d.; Straits tin, £60 13s. 9d.; freights easier.

TRADE AND BUSINESS ANNOUNCEMENTS. — The office of the *Engineering Review* has been removed to the Outer Temple, 222-225, Strand, W.C.—The business of Messrs. J. Jessop and Son, of Leicester, and that of Messrs. Appleby Bros., of London, have been amalgamated, and will henceforth be carried on under the style of "Jessop and Appleby Bros. (Leicester and London), Limited."—The retirement is announced, owing to advancing years, of Mr. James H. Tozer, senior partner in the firm of James H. Tozer and Son, as from January 1st last, and the admission into partnership of Mr. S. Thornely Mott and Mr. George Frederick West, both of whom have been associated with the firm for many years past. The style of the firm remains unaltered.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE home trades outlook is improved by the statement as to the new naval programme and by the second reading of the Light Railways Bill, both of which matters should result in benefit to various trades in this district. At the same time information just to hand as to enormous American steel production is eloquent of Transatlantic prosperity, and of consequent improved orders for various British manufactures. Steel angles and tees are quoted £5 10s. to £6; plates, £5 15s. to £6 5s.; and blooms and billets, £4 7s. 6d. to £4 10s. In the finished iron trade, inquiries are coming to hand for next quarter's supplies, and quotations are firmly upheld. Marked bars continue £7 as the basis price. Merchant bars are £6 5s. to £6 10s. In the sheet trade the mills are well engaged, and it is surprising where all the output goes to. Japanners' steel sheets are quoted about £8 to £8 2s. 6d. for doubles, and £8 15s. 6d. to £8 17s. 6d. for lattens. Hoops are selling at £6 5s. to £6 7s. 6d., and nail rods at £6 10s. In the pig iron trade Northampton and Derbyshire sorts are still 42s. to 43s.; all mine Staffordshires 55s., and medium forge 42s. to 43s. 6d.

The new naval programme, involving the expenditure of £14,000,000 on new works, is regarded with considerable satisfaction in this district by marine engineers, and, indeed, in the numerous trades which contribute various naval requisites in iron and steel—among others, in the chain cable trade. At the present time all the requirements of the Admiralty for chain-cables, &c., are contracted to be supplied from the South Staffordshire and East Worcestershire districts. Gradually, but surely, have South Staffordshire and East Worcestershire become the principal seats of this important industry, there being now in existence only three cable-making firms of any magnitude outside this locality, namely, one at Pontypridd, one at Chester, and one at Gateshead-on-Tyne. About 20,000 tons of iron are annually consumed in the South Staffordshire and East Worcestershire districts in the manufacture of chain cables and chains. Interesting information with regard to this industry has just been laid before the South Staffordshire Institute of Iron and Steel Works Managers by their president, Mr. W. B. Rubery, who is connected with the works of Henry P. Parkes and Co., of Tipton. The first known chain cable was made in 1808, in a small shop in Bell-street, North Shields, by Robert Flinn, an Irishman. In Staffordshire small chain making had been an industry for many years, when in the year 1820 the first chain cable was made by the late Noah Hingley. It was 1½in. diameter, and considered a big undertaking in those days. Chain cables were first made by the late Henry Pershouse Parkes in the year 1825, although he had been engaged in the small chain trade from its beginning. The price obtained for cables in 1825 was about £40 per ton, and gradually went down till in 1850 they were reduced to £12 per ton, and with the reduction in price it is generally admitted that a corresponding falling off in quality took place, very much jeopardising the general adoption of chain cables. It was this deplorable state of things which induced the late Henry Pershouse Parkes to commence welding links on the side instead of on the end or crown of the link, and to use a superior quality of iron in the manufacture of his chains. In the year 1875 the firm of Noah Hingley and Sons, who introduced the cable trade into the midlands, commenced welding links on the side. In the year 1849 chain cables were first made at Saltney by Henry Wood and Co., and they continue making them to this day. Up to about ten years ago no firm in the South Staffordshire and East Worcestershire districts had successfully made cables under contract for the Admiralty, this particular class of work having been principally performed by Brown, Lenox, and Co., of Pontypridd; Henry Wood and Co., at Saltney; and Hawks, Crawshay, and Sons, Gateshead-on-Tyne, when, in the year 1888, the Lords Commissioners of the Admiralty entrusted a five years' contract with the Tipton Green Chain and Anchor Works, which contract was renewed for a further term of five years in 1892, and at this latter date the Admiralty gave a contract to the Round Oak Works, Limited, for the supply of chain cables, &c. In the course of the discussion it was generally considered that fibrous high-class iron would continue to be used for this class of work rather than steel; but some of the members expressed the opinion that steel would take the place of cast iron for the studs which connect the two sides of the links. The above-mentioned body have forwarded to the Board of Trade a resolution in favour of legislation against the use of bogus test certificates being extended to all chains where human life is involved, and not restricted to ship chains only.

A good order for fifteen boilers for Sydney is in course of execution by Mr. Edwin Danks, of the Oldbury Boiler Works, near Birmingham. Five of these have just been shipped, a special train being chartered for their transit to London. The other ten will be forwarded shortly. Each boiler of those completed was 30ft. long by 8ft. diameter, and constructed to a working pressure of 120 lb. per square inch, under the supervision of the Manchester Steam Users' Association. The shell plates were bent up to the extreme edge in vertical rolls, so that there could not be any injury and strain upon the material. All the holes were drilled through the solid after the plates were bent in position. The planing of the shell plates was done in circular form in special horizontal lathes; this method of planing after the bending and drilling avoids the destroying of the bevelled edges, and makes a true lap. All the flue sections were drilled with the two flanges and strengthening ring in position, perfect accuracy of each hole being thus ensured. The thinning of the plates and butt straps was done by special machinery to prevent local heating of the material. The flanging was done by hydraulic pressure at one heat, and the riveting by hydraulic power, and the boilers when finished were tested up to 200 lb. on the square inch. Each stage of manufacture was witnessed by a representative of the Manchester Steam Users' Association, the result being that the boilers were perfect in finish and first class in every respect. The mechanical appliances at these works are exceptionally efficient, and it is conceded by all experts who have visited the establishment and inspected the plant that it cannot be excelled. The success Mr. Danks has attained in the manufacture of high class boilers is indeed well known.

With regard to the Tipton district engineering scheme of the South Staffordshire Mines Drainage Commissioners, the chief engineer, Mr. Edmund Howl, reported to a meeting of that body on Wednesday that negotiations for the sites of engines, wayleaves for hydraulic pipes, and for the driving of underground levels, are still being vigorously pushed forward, and twenty-five draft agreements are in progress. The local authorities had now all intimated their general approval of the scheme with respect to laying hydraulic mains, and in a short time, no doubt, the necessary official consents will be forthcoming. It is hoped that private owners, now that they see the scheme only waiting for the legal agreement to be executed, will render every facility in this direction. The Commissioners' seven engines during the four weeks ending February 26th dealt with a rainfall of ·71 of an inch. There has been a slight increase in the water pumped, but practically it remains at the same low figure at which it has stood for some time past. The seven engines have raised 7,778,166 gallons every twenty-four hours, or 34,721 tons. A comparison of the water pumped in the corresponding month of last year shows a diminution of over 2500 gallons per day.

Good progress is being made with the work of improving the railway approaches into New-street Station, Birmingham. Some delay, however, has occurred in settling certain matters between the London and North-Western Railway Company and the Midland Railway Company, and though these matters are now adjusted, it will be impossible to finish the work by Easter, the time at which it was hoped that everything would be ready. The laying of the permanent way on the new portion of the line known as the Derby deviation has commenced, and trains will be running over it between Saltley and Lawley-street in a few weeks, though they will for some time longer run from the latter point over the old line and through the old tunnel into the station. A slip, the only one of any magnitude since the works were commenced, has occurred in the new embankment near Lawley-street, but this is rapidly being made good with concrete, and the general progress of the work will not be affected.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—At this time of the year there is usually some slacking off, and considering the heavy buying going on recently, it is not at all surprising that there should be a lull with regard to new business just now coming forward. It is also possible that the next few weeks may bring about some slight weakening in prices, at any rate for raw material. It is true that pig iron makers, with very few exceptions, are fully sold, and as I have previously intimated, the bulk of the buying has been for actual requirements. There is, however, always and inevitably a certain amount of over-speculation, and in some cases buyers are already failing to take their full deliveries, with the result that a good deal of iron that has been actually sold is here and there beginning to accumulate in the hands of makers, and it may possibly before long have to be put upon the market. This would, of course, tend to bring prices down, and such a result is in some quarters being looked forward to. The position, taking it all through, is, however, so strong that any downward move in prices could scarcely be more than temporary, and in all probability not to any material extent. Pig iron makers have not been so well sold for many years past, the representative of one large firm, which does a considerable trade in this district, informing me that every portion of their plant was now in full operation—a position they have not been in for many years past; finished iron makers have not had their order books so full for the last four or five years, whilst engineers would probably have to go back over a similar period to find themselves equally well supplied with orders already in hand, and with further new work in prospect, as they are at present.

There was about an average attendance on the Manchester Iron Exchange on Tuesday, with a fair amount of inquiry and a moderate business doing. Prices for the most part were steady at recent quotations, although in some cases not quite so strong at the maximum figures that makers have been asking, whilst amongst merchants there is still underselling. In pig iron buying continues to quieten down, the large users being now generally well covered, and merchants have apparently bought quite as much as they are at present in a position to take. Lancashire makers are, however, selling readily at their recent slight advance, and have no difficulty in getting 46s. 6d., less 2½, for No. 3 foundry qualities, delivered Manchester. The somewhat prohibitive prices that have recently been quoted for district brands are scarcely being maintained, and in Lincolnshire iron 42s. is now in some cases being taken for forge and 44s. for foundry, which is 6d. under the maximum quotations, whilst Derbyshire foundry is, if anything, a trifle easier, and does not average under 46s. to 47s., net cash, delivered Manchester. For outside brands offering here prices continue firm, and moderate transactions are being put through. Makers' quotations for good-named foundry Middlesbrough remain at 47s. 4d., with G.M.B.'s about 46s. 10d., net cash, delivered Manchester. Scotch iron is still quoted on the basis of 47s. 9d. for Eglinton, delivered Lancashire ports, but, as I pointed out last week, the business is steadily drifting from the ports on the Mersey to the Manchester Ship Canal, and for delivery dock quays, Manchester, 50s., net cash, is about the average quotation for Eglinton, whilst for Middlesbrough, which is also being forwarded in considerable quantities by the canal—a cargo of about 1000 tons having come up during the past week—45s., net cash, is quoted delivered at the docks.

In the finished iron trade the position remains much as reported last week; although local makers are, perhaps, not in all cases getting their full recent advance upon bars, it is only on special sales that they make any concession, and they are mostly so well sold as to be indifferent about orders. Delivered Manchester district, £5 12s. 6d. is their minimum quoted prices, with North Staffordshire bars firm at £5 12s. 6d. to £5 15s. per ton. Sheets remain at £7 10s. to £7 12s. 6d.; hoops meet with only a moderate demand, but there are expectations of American orders again being booked in this district, and Association list rates are steady at £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

A continued strong tone prevails in the steel trade, with a gradual hardening in prices. Hematites are in fair request at 57s. 6d. to 58s., less 2½, for good foundry qualities, and ordinary billets are quoted £4 7s. 6d. to £4 10s., net cash, delivered Manchester district. Steel plates and bars are almost 2s. 6d. per ton higher, boiler plates now averaging £6 7s. 6d. up to £6 10s., and bars £6 2s. 6d. to £6 5s., delivered in this district.

In the metal market there has been a good deal of buying during the week, in anticipation of a further upward move in prices. An extra weight of orders has come forward on all descriptions of manufactured goods, and this has been followed by an advance on list rates of ¼d. per lb. all round. This upward move has for the moment acted as a check upon further business, but manufacturers are very firm at their advanced rates, which for delivery Manchester district are as under:—Solid drawn brass boiler tubes, 6½d.; solid drawn brass surface condenser tubes, 8d.; solid drawn copper tubes, 7¾d.; brazed copper gas and steam tubes, 7½d.; brazed brass gas tube, 7¼d.: brazed brass machine tube, 7d.; brass wire, 5¾d.; copper wire, 6¾d.; rolled brass, 5¾d. per lb.

The position throughout the engineering industries of this district continues much the same as I have reported recently. From what I can gather, a considerably increased weight of new work has been given out amongst boiler makers recently, so that in this very important branch of Lancashire engineering establishments must now in most cases be tolerably full of work. Machine tool makers continue to report new work coming forward freely, and the leading firms are full of orders for some time to come, both in heavy and light departments, these including some special tools which are being made for gun work, and water tube boiler construction, whilst Messrs. William Muir and Company, of the Britannia Works, Manchester, who have previously sent out a large number of machine tools to Afghanistan, have just secured further large orders for general tools for the Ameer's arsenal and workshops. These machine tools, some of which when put together are of considerable weight, have, as I have mentioned in referring to previous similar orders, to be specially constructed, so that no single piece shall weigh more than three hundredweight, or be more than 9ft. in length, to meet the requirements of transit over the difficult mountainous country which has to be traversed on the road to Cabul.

I noticed at an exhibition of cycles, held during the past week in Manchester, an ingenious contrivance for operating a pneumatic brake and alarm signal from the steering handle of the machine. This has been brought out by "La Modela" Pneumatic Frame Cycle Company, of Blackburn, and the brake is arranged so that the inflators form part of the handle, the connecting tube running inside the tube of the frame to the back wheel, and reaches to the shoe, where the brake is put on immediately the rider applies his hand to the bulb. The alarm bulb is fixed on the other side of the handle. By the above arrangement the brake and alarm can be used together or separately at the will of the rider, who can put the brake on and sound an alarm simultaneously, without relaxing his hold of the handle, thus satisfying an essential requirement in connection with cycle brakes—that they should be applicable without taking the hands off the handles or the feet from the pedals.

No material change has taken place as regards the coal trade here, except, perhaps, that the position grows worse rather than better. House-fire qualities of round coal have been in rather more active request during the last week or so, but the weight of business doing still falls far short of what is usual at this season of the year, and supplies are plentiful, with prices scarcely more than maintained. Common round coals for steam and forge purposes continue a drug, and are pushed on the market at excessively low figures. Quoted rates are nominally unchanged, but to get rid of surplus supplies representatives of collieries ease down in their prices, and the general tone is weaker. Best Wigan Arley remains at 10s. to 10s. 6d.; Pemberton 4ft. and seconds Arley, 8s. up to 9s.; common house coal, 7s. to 7s. 6d.; and steam and forge coals, about 6s. per ton at the pit mouth. Engine fuel moves off fairly well, so far as the better qualities are concerned; but common sorts continue a drug, and very low in price. Best slack still averages from 4s. 6d. up to 5s.; but inferior descriptions can be bought from 2s. 6d. and 3s. up to 3s. 6d. per ton at the pit.

For shipment there is a moderate inquiry, but only a very limited business doing; with 6s. 9d. to 7s. still about the average figures obtainable for common steam coal, delivered Garston Docks, the High Level, Liverpool, or the Manchester Ship Canal.

Barrow.—Much more life is shown in the hematite pig iron trade, and business during the week has been brisk. Pig iron is going more fully into consumption, and there is a growing demand on the part of users. There is also a large demand on speculative account, but that cannot receive much attention, as makers have not much iron they can dispose of for prompt delivery. Business is likely to increase. Thirty-eight furnaces are in blast, compared with sixteen in the corresponding week of last year. Prices are higher and firmer. Warrant iron is at 49s. 1d. net cash sellers, 49s. buyers, while makers quote nominally 49s. 6d. to 50s. 6d. per ton net f.o.b. for mixed Bessemer Nos.

Iron ore is in better trade. There is a good demand for native qualities, and a comparatively large consumption of Spauish ores for mixing purposes. The latter are quoted at 12s. 9d. per ton, delivered at West Coast ports, and native ores are at 10s. per ton for ordinary, and 12s. 6d. for best descriptions.

Steel makers are busy on rails, hoops, plates, tin bars, and heavy castings. There is an especially brisk inquiry for plates and rails, and orders are already well held.

Shipbuilders and marine engineers are very busy, and are expecting new orders, although during the past few weeks no new contracts have been booked.

The coal and coke trades are more actively employed, and prices are firmer and higher.

There is a proposal, which is gaining much public favour, for the construction of a new light railway up the course of the Duddon from Foxfield on the Furness Railway up to Seathwaite, a distance of eight or nine miles.

Shipping is not very brisk. Exports of hematite pig iron from West Coast ports during last week reached 6836 tons, and of steel 7386 tons, compared with 9034 tons of pig iron and 12,187 tons of steel in the corresponding week of last year, a decrease of 2198 tons of pig iron and 4801 tons of steel. The full shipments of pig iron to date total up to 53,019 tons, and of steel to 67,042 tons, compared with 44,346 tons of pig iron, and 63,114 tons of steel, an increase of 8673 tons of pig iron and 3928 tons of steel.

THE NORTH OF ENGLAND

(*From our own Correspondent.*)

IN every branch of the iron and allied industries there is a steady improvement in progress, and work is now plentiful in most departments, with good prospects of keeping so, taking account of the inquiries that are received and the anxiety that consumers show to purchase. All prices are tending upwards. For pig iron makers the worst part of the year is now practically over, and the spring demand is already setting in freely, as it is apparent that buyers are not likely to better themselves by waiting. Not only are shipments of pig iron good, but there is an increasing consumption at the local and inland works—in fact, it is several years since there was anything like so large a local consumption; and the proposed reopening of idle works will tend to increase the requirements still further. It is very satisfactory to find so pronounced an improvement in the industries allied to the iron trade. The turn for the better was generally delayed for some time beyond its appearance in iron and steel, but now that it has come it is progressing pretty quickly. More especially is this so in the engineering and bridge-building trades; and some firms have never been more fully supplied with orders than they are at present. The extra work given out has made the competition less keen, and there is now some chance of more favourable prices being realised.

Cleveland pig iron prices have been further advanced this week, No. 3 by 6d. per ton, and the commoner qualities by 3d. per ton. Business in No. 3 g.m.b. pig iron for prompt f.o.b. delivery has been generally done at 38s. 6d. per ton, and it is not much that can be bought at that figure now. This represents an advance of 2s. 6d. since the worst price of the year was reported, viz., in the early part of January, and the price is now only 1s. below the best price of last year. For April delivery, 38s. 9d. is readily paid, and some of the leading brands are realising fully 39s. No. 4 Cleveland foundry pig iron has been raised to 37s. 3d., grey forge to 36s. 9d., mottled to 36s. 3d., and white to 35s. 9d., all for early delivery. Cleveland warrants have improved in value very satisfactorily, Wednesday's price being 38s. 8d. cash sellers. The stock of Cleveland pig iron in Connal's stores at the end of February was 185,510 tons, the increase for the month being 4717 tons, whereas in January the increase was 9093 tons, and in December 15,352 tons. Of hematite pig iron Messrs. Connal and Co. hold 145,396 tons, an increase of 3814 tons. No. 1 Cleveland pig iron is only 1s. dearer than No. 3, whereas formerly it was 2s. 6d. to 3s. 6d. dearer. Mixed numbers of East Coast hematite pig are realising 47s. for this month's delivery, and 47s. 6d. for April. Rubio ore is in better request, and 12s. 9d. per ton delivered at wharves on the Tees has to be paid for it.

The February statistics of the Cleveland Ironmasters' Association were quite as satisfactory as had been looked for. It was estimated that there would be an increase of 20,000 tons in the stocks of Cleveland pig iron, and the actual figures are 19,657 tons, the total stock held of that description being 351,854 tons, which is nearly eleven weeks' make. Of this the makers held unsold 111,013 tons—2907 tons increase; in their stores were 30,511 tons—10,133 tons increase; in the North-Eastern Company's stores 24,820 tons—1900 tons increase; and in Connal's 185,510 tons—4717 tons increase. The most noticeable feature is the large increase in makers' stores, there being an increase of 50 per cent. This represents iron that has been bought and paid for by consumers and merchants, and it is kept in makers' yards until the buyers can take it out. Two furnaces were blown in during the month—one at Messrs. William Whitwell and Co.'s Thornaby Ironworks, and one at Consett Works, both to produce hematite iron. Of the 96 furnaces in operation at February 29th—two more than at January 31st—there were 52 making Cleveland pig iron and 44 making hematite, &c. Altogether 134 blast furnaces are built in the North of England, against 141 a year ago. The production of pig iron was 130,001 tons Cleveland iron, 12,315 tons decrease on January; and 124,779 tons hematite, basic, and spiegel iron, 12,100 tons decrease on January; total, 254,780 tons, decrease 14,415 tons. The shipments of pig iron from the Cleveland district amounted to 69,264 tons, a decrease of 476 tons in January, but an increase of 20,432 tons, as compared with February, 1895. Last month's shipments included 7465 tons of hematite, &c., whereas in January 8406 tons were despatched.

The finished iron and steel trades are active, and business steadily improves. Heavy steel rails are firm at £4 15s. net at works, and this is the lowest price that is allowed by the combination to be accepted for home and colonial orders, where foreign competition does not come in. Where, however, there is foreign competition, manufactnrers get what price they can. The North-Eastern Steel Company's rail mills at Middlesbrough have been idle for a month, not because of any lack of orders, for these were never more plentiful, but because of the alterations that are being carried out at the works. These alterations have been in progress for several months, but it has been found necessary during the last month, active though trade undoubtedly is, to altogether close the establishment, in order that the extensions and alterations may be completed. The production of the mills hitherto has been about 2500 tons per week, but the improvements will enable the firm to increase this by 25 per cent., and will bring about a considerable saving in labour.

The directors of Messrs. Bolckow, Vaughan, and Co., have declared a dividend for 1895 of 3 per cent., as compared with 2½ per cent. for each of the previous three years, 6 per cent. in 1891, and 6 per cent. in 1890. The amount of profit available for distribution, after providing for depreciation, is £160,015 19s., and with the amount brought forward from 1894, there is £174,636 7s. 2d. available for the shareholders. Of this £120,891 is paid to them, £15,000 is to pay for new blast engines for the hematite furnaces, £25,000 is added to the reserve fund, and £13,743 is carried forward. The directors state that the condition of trade during the first seven or eight months of 1895 was rather worse than in 1894, prices being even more depressed, and orders more difficult to obtain. Towards the autumn an improvement was experienced in the demand for pig iron and finished steel, the trade outlook became brighter, and under these influences prices rose. Although pig iron did not quite maintain its position, and coal never shared in the otherwise general improvement, the year closed with better prospects for the future than has been apparent for a considerable time.

The shareholders of the Tees side Iron and Engine Works Company, Limited, Middlesbrough, have ratified the agreement which the directors have made to sell the whole of their works to Sir Christopher Furness. He has now paid the required deposit, and has taken possession. What chiefly caused the directors to sell were the losses that have been made in carrying on the works. At the end of 1894, according to the balance-sheet, the balance against the company on profit-and-loss account was £13,135 3s. 7d., and last year's operations resulted in a loss of £7894 12s. 3d., which, with the interest on loans, £3102 1s. 8d., made the deficit for 1895 no less than £10,996 13s. 11d., and altogether the profit-and-loss account was £24,131 17s. 6d. against the company. The agreement is that Sir C. Furness shall take the works, plant, tools, materials, stores, work in progress, and debts owing to the company, altogether valued at £144,000, and he pays the liabilities of the concern £105,611, and gives the preference shareholders who have paid 20s. each for their shares 7s. 6d. per share if they require it in cash, or 10s. if they take it in preference shares in any company or companies which Sir Christopher may form to work the properties. This means £33,000 if all the shareholders elect to have cash for their shares, or £44,000 if they take shares. The new company or companies are to be formed by May 15th, and each preference shareholder must then say whether he will accept cash or shares for his holding.

In connection with the disastrous boiler explosion which occurred on June 14th last at the Redcar Ironworks, when twelve men were killed and nine more injured, there has arisen some dispute as to the compensation due under the Employers' Liability Act, which may lead to the whole case being fought over again in the law courts. Messrs. Walker, Maynard, and Co. have paid over to the men's representatives the sums which have been agreed upon, and these sums they ask the accident insurance company with whom they were insured to refund. The insurance company, however, hold that they are not liable, for, although the Coroner's jury found that the explosion was an accident, the Board of Trade representatives held that it was not an accident, "and the verdict of Government officials of course overrides that of the Coroner's Court." Messrs. Walker, Maynard, however, contend that even if this were so they are entitled to the compensation, as their policy covered the negligence of their servant.

Mr. E. T. M. Cowburn, of Hull, has been appointed manager of the Stockton Corporation Quay, vice Mr. Ballon, who has been appointed dock superintendent of the North-Eastern Railway Company's Dock at Middlesbrough. There were about 160 applications for the post.

A company is being formed for the purpose of laying down a railway between Chathill, on the North-Eastern Railway and Seahouses, North Sunderland. The line, which will be single, will be about four miles long. The proposed Durham Coast Railway is practically in abeyance at present, the Town Clerk of West Hartlepool having received information from the general manager of the North-Eastern Railway that it was impossible to make any progress, as the parties interested in the coal borings apparently were not yet prepared to proceed with any works connected with mining operations. The Town Clerk, however, calls attention to the evidence given before the Committee of the House of Commons that such operations would not be commenced until a railway was provided, and that this was the generally accepted view. The directors are, therefore, to be urged to reconsider their determination.

The question of the shipwrights' wages on the North-East Coast has not yet been settled, but another conference of employers' and men's representatives is to be held, and meanwhile the men are continuing at work. The employers offered 5 per cent. advance.

A new departure in marine engineering has been made at West Hartlepool, where the Inchmona, a new screw steamer, is to be fitted with the first set of Mudd's patent five-cylinder and four-crank engines, with boilers working at a pressure of 255 lb. per sq. inch under induced draught. Mr. Thomas Mudd, the inventor, is the Mayor of Hartlepool, and is the managing director of the Central Marine Engine Works, which will supply the engines. The object of the invention is to obtain a greater economy of fuel than has been possible with the triple-expansion engine. It is little more than thirty years since the introduction of the compound engine with a boiler pressure of 65 lb.

At Elswick on Friday Sir W. G. Armstrong and Co. launched the Japanese battleship Yashima, the largest vessel ever constructed on the Tyne, having 12,300 tons displacement, and thus being 1000 tons heavier than H.M.S. Victoria, which was also built at Elswick. The Yashima is 412ft. long over all, has a maximum breadth of 73ft. 6in., and a depth of 43ft. 7½in. The armour belt is 226ft. long by 8ft. deep, and the maximum thickness is 18in. All the thick armour is face-hardened on the Harvey principle. The estimated horse-power is 10,000, indicated with natural draught, and 13,500 with forced draught, the corresponding speeds being 16¾ and 18¼ knots.

At the annual meeting of Smith's Dry Dock Company a dividend of 5 per cent. on the preference shares and 10 per cent. on the ordinary shares was declared. The company did 25 per cent. more work in 1895 than in 1894. The number of vessels docked was 130 last year against 112 in 1894, and 108 in 1893. A new pontoon dock will be launched this month, which it is expected will be at work in three or four months.

The coal trade is showing a slight improvement. The Executive of the Durham Mining Federation Board have issued a circular to the men asking them to reconsider their decision for the abolition of the Conciliation Board.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE short spell of cold weather experienced at the beginning of last week beneficially affected the house coal industry. The improvement was not great enough, however, to make much alteration in the working of the pits. At the time accumulations were very large, and the extra consumption only served to reduce in a small degree the heavy stocks. Several threatened strikes have for the present been averted, although it is not unlikely that more serious complications must inevitably ensue before long. The demand for coal, particularly in the household sorts, is, with rare exceptions, most unsatisfactory. The South Yorkshire pits are not, as a rule, working more than three or four days a week, the latter being the exception. A week or two of cold weather would have made all the difference in house fuel. Several gas coal pits are well employed. There has been a good deal of speculation recently in coal buying by merchants. Their operations, which have been in steam coal for export, have had further depressing effect upon values.

The metropolitan and southern markets are taking but a moderate tonnage, London agents reporting only a quiet business. An average quantity of both gas and house fuel is being forwarded to the eastern counties as well as other markets. Prices have an upward tendency in gas sorts, although very little change has occurred up to the present. Quotations are as follows:—Silkstone coal is purchaseable at 8s. 3d. to 8s. 9d. per ton for best qualities, and 7s. to 7s. 3d. for secondary sorts. Barnsley house fuel is at 7s. 6d. to 7s. 9d. per ton at the pits, with thin seam coal hard to sell at 6s. to 6s. 3d. per ton. The steam coal trade remains in practically the same condition.

Trade is quiet, with stocks rapidly accumulating. The business done at Hull and the other Yorkshire ports has not been equal to the figures of the previous year, notwithstanding that many of the leading colliery owners in this district are transacting a large trade. Values range from 6s. 6d. to 7s. per ton. The various railway and other companies are taking an average tonnage on contract account. Small coal and slack are moving rather more freely than they did a week ago; supplies, however, are still abundant, and prices remain stationary. Best screened slack is obtainable at from 3s. 6d. to 4s. 3d., with ordinary pit slack at 2s. 3d. to 2s. 6d. per ton at the pits. Coke is in better request, which is due to an improvement in the smelting industry, and an increase in the number of furnaces in blast in North Lincolnshire.

In the iron trade there is a decidedly firmer tone, both at Glasgow and in the hematite market. Hematite pig iron is offering this week at Sheffield at 58s. per ton for West Coast, and 55s. to 56s. per ton for North-East Coast. Lincolnshire forge iron, 39s. 6d. net cash; bar iron, £5 10s. to £5 12s. 6d. at makers' works. Siemens-Martin steel, average quality, £7 10s.; Bessemer billets, special carbons used in the Sheffield trades, make £5 12s. 6d. to £6.

The heavy industries are full of work in every department. The armour plates now being produced under the Spencer programme will keep the three works well employed into next year, and the establishments will have added to these the plates required for the five battleships of the Renown type which form the chief feature of the Goschen programme. The cruisers and the torpedo craft will furnish further work for this district. Armour is also being made for Japan, and other foreign Governments are making inquiries which are pretty certain to lead to extensive business. Makers of gun forgings and the lesser calibres of shot and shell are in receipt of fair orders, though not equal to the powers of output. The orders for the larger descriptions of armour-piercing projectiles do not come in, and the new work required under the Naval Estimates is eagerly looked for.

The railway material trade is exceptionally brisk, the home orders being heavy, while satisfactory orders have been booked for the Indian State Railways, the West Indies, and on foreign account. Prices are tending upwards for tires, buffers, springs, axles, and locomotive wheels. The machine department, which has been the last to show much animation, is now promising, local houses having received some remunerative work during the last few days. Manufacturers of boilers, &c., report a good business. All classes of castings are freely inquired after, and many houses find it extremely difficult to supply their customers as early as they desire. The makers of the steel portions of dynamo and other electrical appliances are full of work, and likely to be so for some time to come.

An improvement has to be noted in the lighter trades, although it is not to be compared with the advance in the heavy industries. It is expected that the next quarterly return of exports from this district to the United States will show an increase on the figures for the corresponding period of 1895. The British Government contract for tool steel, which is an important item, has just been placed with a Sheffield firm for three years. The edge tool makers are well off for work. Some complaint is heard in the cutlery and electro-plating departments, but the leading houses have no cause of complaint, as they are generally making full time.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been a firmer tone in the iron market in the last few days. The conditions of business are all favourable, and a variety of considerations serves to give a cheerful aspect to the trade. Shipments of pig iron from the Scottish ports were again better than usual this week, although it is still observable that the increase is rather in the coastwise than in the foreign department of the trade. It is possible, however, that this branch may make some forward movement ere long. The substantial improvement in the manufacturing trades gives the assurance of a steady consumption of raw iron for a considerable time to come. Both English and Scotch pigs are more in request. Ordinary Cleveland iron will be more wanted presently, and the imports into Scotland are already much greater than at this time last year. For hematite pigs the demand is also increasing, and there is a steady advance in prices. The great demand for rails and other articles has had a good effect on the market. Large orders have just been placed with Clyde shipbuilders and engineers, who had already a good supply of work, and the announcement of the new naval programme has tended to confirm and support the general improvement.

The pig iron warrant market has been fairly active, but there has not been so much speculative business as might have been anticipated. Indeed, the favourable state of matters which now exists appears to have been largely discounted by speculators; and, indeed, the prices of iron already show a substantial advance from the lowest level. Business has been done in Scotch warrants up to 47s. 8d. cash and 47s. 10d. one month. Cleveland warrants were done at 38s. 9d. cash, and 38s. 11d. one month; and Cumberland hematite, 49s. 2d. cash and 49s. 4d. one month.

The consumption of hematite pig iron is steadily increasing, both Scotch-made and Cumberland iron being in increasing demand. The current output of Scotch hematite is from 2300 to 2500 tons per week larger than it was at this time last year. Great activity exists in the ore import trade, as may be inferred from the fact that at Ayr Harbour alone upwards of 8000 tons were discharged in the course of the past week. The arrivals at the other Clyde and Forth ports are proportionately increased.

There are 35 furnaces making hematite, 41 ordinary, and 3 basic iron, the total number now blowing in Scotland being 79, against 74 in the corresponding week of last year.

Prices of makers' special brands of pig iron are steady to firm. Govan, Monkland, and Carnbroe, Nos. 1, are quoted 48s.; No. 3, 46s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, Calder, and Summerlee, No. 1, 51s.; No. 3, 48s. 6d.; Coltness, No. 1, 53s. 6d.; No. 3, 48s. 6d.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 46s. 6d.; Eglinton, No. 1, 48s. 6d.; No. 3, 46s. 6d.; Dalmellington, at Ayr, No. 1, 48s.; No. 3, 46s.; Shotts, at Leith, No. 1, 53s.; No. 3, 49s.; Carron, at Grangemouth, No. 1, 53s.; No. 3, 49s. 6d.

The shipments of pig iron from Scottish ports in the past week has been 7691 tons, compared with 5062 in the corresponding week of last year. There was dispatched to Italy 350 tons; Germany, 440; United States, 25; Holland, 480; Canada, 25; France, 50; Australia, 10; Belgium, 750; Spain, 39; China and Japan, 288; other countries, 225; the coastwise shipments being 5009, against 2665 in the same week of last year.

The present improved prices of pig iron stimulate the production, and are leading to some increase in storing; but the current requirements of the trade are such that there is not much likelihood of the stocks being very largely augmented.

In the steel trade there is great activity, with a certainty of busy trade for a long time. Finished iron is active, with a firm tone. The different engineering and manufacturing branches are astir with increasing business, and the outlook altogether is very encouraging.

The coal trade has exhibited no real improvement. Shipments and home consumption are fair, but supplies are heavy, and the prices continue at the lowest point. Coalmasters are obliged to reduce the colliers' wages, which is now being generally done, and great dissatisfaction is thereby being caused among the men.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

ANOTHER good coal week has been experienced at Cardiff, the total exports for the past week reaching 315,000 tons. It was stated on 'Change, early in the week, that March promises to be one of the busiest months in the year. Newport, Mon., total, coastwise and foreign, was a fair average. Swansea a little below the average, its French trade as usual prominent. American trade not quite so good as usual in respect of coal.

I referred last week to the stoppage of the Aberdare-Merthyr Colliery, and the possibility of a reconstruction of the company and a restart. An indirect reply to this "hope" is given by a semi-official announcement that nothing of that kind will come about unless royalty owners very considerably reduce the terms upon which the colliery has hitherto been worked. "Given a substantial reduction of royalties, reconstruction may be possible, not otherwise."

Mid-week on the Cardiff Exchange the coal market did not show any great activity, due principally to the storms. Best steam coal was quoted at 10s. to 10s. 3d.; seconds ranged from 9s. 6d. to 10s.; and drys from 9s. 3d. to 9s. 6d. Best Monmouthshire was rather dull at 8s. 6d.; seconds, 8s. One of the principal "grumbles" was at the stagnation of small coal. Best sold for 4s. 6d.; seconds, 4s. to 4s. 3d.; drys from 3s. 6d. The stormy weather, and consequent delay in arrival of tonnage, told badly the beginning of the week upon house coal. The last prices, Cardiff, were as follows:—Best, 10s. 6d. to 10s. 9d.; No. 3 Rhondda, 9s. 6d. to 9s. 9d.; brush, 7s. 9d. to 8s.; small, 6s. to 6s. 3d.; No. 2 Rhondda, 7s. 6d. to 7s. 9d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d. Swansea prices are:—Steam, 9s. 6d. to 10s. 3d.; seconds, 8s. 9d. to 9s. 3d. House coal: No. 3 Rhondda, 10s. to 10s. 6d.; No. 2, 8s. 9d. to 9s. 6d.; anthracite, 8s. to 11s. 6d., according to quality.

Coke at Cardiff is in good demand, and last prices are firmly maintained. Satisfactory accounts are to hand of the patent fuel trade. Cardiff and Swansea prices are from 10s. to 10s. 3d. Swansea's export last week was 5546 tons. On 'Change, Swansea, this week it was reported that the finished iron and steel trade was fairly busy; and that home, colonial, and foreign rail business is tolerably hopeful. On the 28th ult. 500 tons went to London, and on March 3rd 300 tons to the same destination, both from Newport. Swansea quotations this week were as follow:—Pig iron, 4d. per ton advance from previous week; Glasgow warrants, 47s. 7d.; Middlesbrough No. 3, 38s. 8d.; hematite, 46s. 6d.; Welsh bars, £5 10s. to £5 15s.; sheets, iron and steel, £6 12s. 6d. to £6 15s.; steel rails, heavy sections, £4 10s. to £4 15s.; light, £4 17s. 6d. to £5 5s. Sleepers, angles, channels, &c., according to specification. As regards railway steel, I may state that 350 tons railway chairs came to Swansea this week from Middlesbrough for the Rhondda and Swansea Bay Railway.

Bessemer steel is quoted at £3 17s. 6d. for bars, and Siemens best for £3 18s. Tin-plates figure in quotations at the usual low rates. Bessemer cokes at 9s. 1½d. to 9s. 3d.; Siemens, 9s. 3d. to 9s. 4½d.; ternes, from 17s. 6d. to 22s. 6d.; best charcoal, 12s. 6d. to 13s. 6d. In the prosperous days of Melingriffith charcoal plates sold for £2 2s. a box, and the proprietary stocked them if prices fell, just as Crawshay did his puddled bars when markets drooped.

I have still little encouraging news about the tin-plate trade. According to leading authorities one third of the trade has fallen away from Wales. Exports last week, if a shade better, were very insignificant. The total shipped was 18,496 tons, and the receipt from works 33,090 boxes. Stocks are creeping up, totalling now 33,090 boxes. The great falling off is in the American trade; continental business being still satisfactory. Newport is shipping substantial "parcels" to London. I note amongst a crowd of bad signs, a few good ones, such as Gwendraeth difficulty is over, after a stoppage of two months, and a restart is preparing. The leading opinion is that some little time must pass before any improvement sets in generally.

Prospects of the pitwood trade are not encouraging; quotations are fixed in Cardiff at 15s. 3d., but I am assured by one engaged in the business that sales are generally at 15s., and he prophecies that they will be down to 14s. 6d. before a month is out.

Amongst the arrivals from America last week was a steamer with a part cargo made up of 900 tons slates, and the rest made up of oil and grain, and yet it is said that North Wales slates are amongst the best in the world. A quick sail from St. John's, New Brunswick, was noted a few days ago at Cardiff. It was done in seventeen days.

Iron ore is brisk, prices firm. Dowlais received three cargoes one day this week, and the import into Swansea last week amounted to 4750 tons.

In their new water scheme the Newport, Mon., Committee have gone the right way to work. They have consulted an eminent geologist, who has recommended the practicability of the works at Wentwood, and in accordance the Committee now recommend the Corporation to take up the undertaking. It is estimated that the extra work will cost close upon £50,000.

The local relief fund at Tylorstown acknowledges the receipt of £1345 in aid of the widows and orphans from the late explosion.

A conference of the Sliding-scale Committee is announced for Saturday at Cardiff, when the discharge note question is to be threshed out. The opposition is spreading. The feeling appears to have been intensified by the Plymouth lock-out, which continues as gloomy as ever. The discharge note principle is that unless colliers have their notes of discharge from last place of employment, no one will employ them, as it is then assumed that they are either men out on strike or are locked out. At Ebbw Vale this week very strong speeches were made against the system, and the tendency there and elsewhere is to give a month's notice unless the plan is withdrawn. I am still inclined to think that the sliding scale will settle the difficulty amicably.

I note that in the House of Lords on Monday the Cambrian Railways Bill, the Taff Vale Railway Bill, Windsor Dock (Cardiff) Bill, and the three Great Western Railway Bills were read a second time.

An excellent authority tells me that there is something in the rumour of a great industry being transferred to the marshes at Barry, but that facts, names, dates, &c., are not allowed to come out yet. Public opinion has been inclined to the belief that one of the Welsh iron works was about to slide down from the hills. This, however, is stated not to be the case. The industry is an English one.

Trouble is threatened at the Hardy Colliery. Lately a labour dispute occurred there, which was submitted to arbitration, but the "rippers" refused to abide by the decision. There is a fear that if this cannot be arranged, a stoppage will take place which will involve 1500 men. There used to be a rule amongst the more thoughtful of the colliers not to raise dangerous points when labour was abundant, as is now the case, with several large collieries stopped; but this seems to be overlooked, and in the face of a good demand for coal, the men in many parts of the district are agitating.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE reports that come in from the different iron markets are of an encouraging character. Trade is generally becoming more favourable as the year progresses, nearly all branches of the iron and steel industry experiencing an improvement in demand, while prices for most articles increase.

A good business is done on the Silesian iron market, both as regards raw and manufactured iron. For steel and general hardware there is likewise a healthy demand coming forward, and quotations are reported to be firm.

From the Austro-Hungarian iron market improving accounts are being received, especially with regard to the malleable iro department, where numerous inquiries have been coming in upon the week. Girders are in particularly good request; also for railway and engineering requirements a brisk demand is experienced, and in agricultural implements a good business is anticipated for the next month. Official quotations are, on the whole, unchanged; only here and there a slightly improving tendency has been perceived.

There is a better tone on the French iron market, owing to the lively inquiry that has been coming in for most articles last week. A Bar and Girder Convention, of which there has been much talk for some time past, has at last been formed for a period of five years, twenty-three mills belonging to it. The following figures show French business in coal and coke during the last three years:—

Import.

Coal.	1895. Tons.	1894 Tons.	1893. Tons.
From England	4,290,186	4,218,516	3,973,518
From Belgium	3,868,650	3,851,057	4,117,965
From Germany	581,959	663,139	691,737
From other countries ..	7,812	2,894	2,377
Totals	8,748,607	8,735,606	8,785,597
Coke.			
From Belgium	431,300	470,032	513,727
From Germany	973,300	1,044,820	896,920
From other countries ..	8,350	15,130	33,172
Totals	1,412,950	1,529,982	1,443,819

Export.

Coal.	Tons.	Tons.	Tons.
To Belgium	430,780	327,869	343,340
To Italy	17,810	26,434	31,896
To Switzerland	203,710	197,459	204,216
To Turkey	4,440	10,674	11,062
To Egypt	250	294	6,290
To Algiers	8,390	14,860	4,266
To other countries	155,650	170,735	214,076
Totals	821,040	748,336	815,146
Coke	84,580	57,031	58,606

In Belgium the iron trade is moving on briskly. Demand is active for most sorts of iron, and prices are, on the whole, pretty satisfactory, although, of course, there is still much left to be desired. Foundry pig is in particularly good request, and No. 3 is scarcely obtainable at 47f. p.t. Rails, too, have been realising better prices lately.

The condition of the Rhenish-Westphalian iron market is much the same as last week, an improving tendency prevailing in all departments both with regard to prices and inquiries. Buyers come forward freely with their orders, perceiving that waiting longer means paying higher prices. A fair amount of work has consequently been booked upon the week, and a cheerful tone is everywhere noticeable. Iron ore is very lively, and purchasers had to agree to advances in quotations in a number of cases. Officially M. 8·60 p.t. is quoted for spathose iron ore, roasted ditto fetching M. 11 to 12·70 p.t.; calcined iron ore costs M. 12 to 14 p.t. For Nassau red iron ore, 50 p.c. contents, M. 9·30 p.t., free Dillenburg, is paid. There is a brisk business doing in the better qualities of Luxemburg-Lorraine minette to Westphalia and the Rheinland, minor sorts going to Belgium and the Longwy district. Quotations are, for red minette, 40 p.c. contents, M. 3·20 to 3·30 p.t., the 37 p.c. quality being sold at M. 2·40 to 2·70 p.t., net at mines. In the pig iron trade the business done upon the week has been altogether a satisfactory one. All sorts of crude iron are in good call, basic being particularly well inquired for, and there is a tendency upwards in prices. Last week's quotations were, for spiegeleisen, 10 p.c. to 12 p.c. grade, M. 54 to 55 p.t.; forge pig, No. 1, M. 49 to 52 p.t.; No. 3, M. 42 p.t.; hematite, M. 65 p.t.; foundry pig, No. 1, M. 65 p.t.; No. 3, M. 56 p.t.; basic, M. 52 p.t.; Bessemer, M. 54 to 55 p.t. at works. Luxemburg forge pig is quoted M. 56·50 p.t. free Luxemburg. All the branches of the malleable iron industry have continued healthily occupied, but, as prices for raw material are steadily increasing, those realised for manufactured iron still leave very little or no profit, and makers justly complain of the low rates they are forced to accept. In bars a particularly brisk business was doing last week, and hoops and girders have also been in fair inquiry. In the plate and sheet trade demand is active, but quotations remain low, although for the last-named article an upward inclination can be perceived. Drawn wire has improved in price as well as in demand. The situation of the tube foundries is pretty satisfactory, prospects for spring business being much more favourable than was at first anticipated; M. 110 p.t., free at works, may be considered as basis price. Machine and construction shops are irregularly occupied, but there is an improving tone noticeable nevertheless. The wagon factories are well situated, with very satisfactory prospects.

Latest list quotations, per ton at works, are as follows:—Good merchant bars, M. 115; angles, M. 120 to 125; girders, M. 85, free Burbach; hoops, M. 123 to 125; billets, in basic and Bessemer, M. 83 to 85; heavy plates, for boiler-making purposes, M. 160; tank ditto, M. 135 to 140; steel plates, M. 130 to 135; tank ditto, M. 115 to 120; sheets, M. 140 to 150; drawn wire in iron or steel, M. 118 to 135; iron wire rods, common quality, M. 118; wire nails, M. 127 to 130; rivets, M. 155 to 160; complete sets of wheels and axles, M. 270 to 280; axles, M. 200; steel tires, M. 195 to 200; Bessemer rails, M. 108 to 110; steel sleepers, M. 106; fish-plates, M. 112 to 120; light section rails, M. 95.

In last week's letter we gave the figures of German import and export for 1895; we are now enabled to state the value of German foreign trade for the same year. The difference against 1894 is put in parentheses:—

	Import. M. 1000.	Export. M. 1000.
Iron ore	26,424 (-1021)	7,440 (- 228)
Pig iron	8,783 (- 722)	7,035 (- 1,014)
Angles	12 (- 11)	17,118 (+ 4,198)
Fish-plates, sleepers, &c. ..	60 (- 19)	4,562 (+ 228)
Rails	146 (- 137)	9,680 (- 231)
Bars	2,818 (- 28)	27,827 (- 2,222)
Plates and sheets	565 (+ 71)	16,417 (+ 4,498)
Iron wire	1,770 (+ 200)	25,945 (- 384)
Iron manufactured goods	8,426 (-1208)	107,580 (+ 9,002)
Hardware	6,655 (+ 66)	68,980 (+21,602)
Locomotives, traction engines	1,902 (- 509)	8,887 (+ 2,417)
Other machines	28,420 (+2195)	86,777 (+ 8,560)

According to the *Vossische Zeitung*, no less than 526,785,000 pud coal were produced in Russia in 1894, against 367,204,000 pud in 1890; in 1885 only 260,578,600 pud were produced. In iron ore 102,140,000 pud were produced in 1893, and 128,010,000 pud in 1894. Output of pig iron in Russia was, for 1894, 80 million pud, against 40 million pud in 1893. Out of these 80 million pud crude iron, 30,090,000 pud steel and 27,574,000 pud malleable iron were made.

4239. Pencils, H. H. Seaman, London.
4240. Coin-freed Gas Meters, R. T. and J. G. Glover, London.
4241. Drying Apparatus, C. G. J. Möller and P. Pfeifer, London.
4242. Making the Front Forks of Cycles, R. W. Smith, Birmingham.
4243. Chain Padlocks, D. Waine and I. Waine, Birmingham.
4244. Chromo-photography, C. D. Ahrens, Hampton Hill, Middlesex.
4245. Gas or Oil Traction Cars, H. P. Holt, London.
4246. Speed Governors for Steam Engines, J. Dow, London.
4247. Apparatus for Visible Signalling, L. Sellner, London.
4248. Tempering of Armour Plates, H. V. Holden, London.
4349. Paint Removing Compounds, W. P. Thompson.—(*C. S. Bailey, United States.*)
4250. Collapsible Boats, M. T. Reade, Liverpool.
4251. Cycle Saddles, S. Bernstein, Liverpool.
4252. Water-tight Revolving Doors, P. Arschauloff, Liverpool.
4253. Compressing and Storing Air, E. C. Nichols, London.
4254. Driving Band Chain or Belt, A. J. Caronni, London.
4255. Steam Engines, H. J. Haddan.—(*The Prosser Steam Engine Company, United States.*)
4256. Jumping Pipes, E. Neumeister and R. Sobotka, London.
4257. Liquid Dispensing Apparatus, W. M. Fowler, London.
4258. Operating Tables, R. Kny, London.
4259. Vehicle Propulsion, E. J. Clubbe and A. W. Southey, London.
4260. Coffee Pots, H. Nicholson, London.
4261. Electrical Lamp, H. J. Dowsing and J. S. Keating, London.
4262. Fish Hooks, F. M. Robinson, London.
4263. Device for a Bottle Neck, C. C. Brown, London.
4264. Cycle Stands, E. A. Lefebre, jun., London.
4265. Cycle Locks, C. H. Reed, London.
4266. Evaporative Condensers, &c., H. J. Fraser, London.
4267. Ladies' Cycling Skirts, W. Fletcher, London.
4268. Vehicles, M. R. Ward, London.
4269. Working Parts of Road Vehicles, M. R. Ward, London.
4270. Artificial Stone Slabs, &c., K. Erdmann, London.
4271. Handles and Handle-bars of Cycles, F. E. Strangward, London.
4272. Bronzing Machines, S. N. Freeman, London.
4273. Window Blind, W. McLaren, London.
4274. Railway Carriages, J. J. Needham, London.
4275. Folding Cards, W. A. S. Hickson and E. D. Ward, London.
4276. Metal Roofing, B. Silbersztein, London.
4277. Tea Pots, Coffee Pots, &c., A. T. Hollely, Sheffield.

26th February, 1896.

4278. Gripping Power of Pulleys, A. J. Hunter, London.
4279. Sash Holder, J. Webster, J. T. Woodhouse, and F. J. Bramwell, Sheffield.
4280. Permanently-lined Tennis Court, G. B. Willis, Birmingham.
4281. Fountain Penholder, H. Andrews, Birmingham.
4282. Sewer Entrance Covers, W. H. Morgan, Birmingham.
4283. Making Bottles, J. Meadowcroft and W. Meadowcroft and Son, Ld., Halifax.
4284. Surface Condensers of Engines, J. Rhodes, Halifax.
4285. Method of Burning Acetylene Gas, J. R. Wigham, Dublin.
4286. Making Photographic Plates, C. O. Weber, Manchester.
4287. Cycle and Carriage Bracket, G. R. Knight, Southsea.
4288. Writing Tablets for Schools, W. Smithies, Birmingham.
4289. Questioning Machine, H. Newman, Birmingham.
4290. Articles of Jewellery, W. Needham, Birmingham.
4291. Golf Clubs, W. L. Bullows, Birmingham.
4292. Grinding Machines, R. F. and H. S. Pochin, Leicester.
4293. Operating of Churns, H. Gallagher, Glasgow.
4294. Scraping Pipes, H. J. I. Bilton and T. Timmins, Birmingham.
4295. Clock Frames, S. M. A Jeantet, Manchester.
4296. Manufacture of Boots and Shoes, H. Stevenson, A. W. Stevenson, and J. Gerrard, Manchester.
4297. Attaching the Flanges of Warpers' Beams, J. Mills, Manchester.
4298. Sanitary Pipes, C. R. Soar, Derby.
4299. Tool for Splicing Ropes, &c., C. Bottomley, Glasgow.
4300. Articles of Sheet Metal, W. H. Wood, jun., and W. T. Scrivens, Birmingham.
4301. Spouts of Tea Kettles, &c., G. G. Ford, Neath.
4302. Trunk Appliances, E. A. Ricketts, Wolverhampton.
4303. Domestic Baths and Basins, T. B. Ralston, Glasgow.
4304. Combined Bottle Stopper, F. F. Measures and F. Adams, London.
4305. Ventilation of Vans, &c., J. G. L. McLachlan, Glasgow.
4306. Alarm for Prepayment Gas Meters, S. H. Chidley, London.
4307. Hammocks, G. Perry, Birkenhead.
4308. Perambulators, W. D. Rowlingson.—(*F. von Zawalzky, Germany.*)
4309. Boot Trees, O. Stuart and T. H. Ashcroft, Liverpool.
4310. Motor Engines, C. G. Morgan and H. E. Coulson, London.
4311. Tires, H. Godsal, London.
4312. Loom Shuttles, T. Stones and J. Stead, London.
4313. Finding the Pick in Looms, C. W. Parratt and C. Fell, London.
4314. Gas Meters, F. Moore, London.
4315. Form of Propellor for Vessels, G. C. J. Topp, London.
4316. Pegs, A. A. King, London.
4317. Spiral Railways, G. Zahikian, London.
4318. Pipe Cutters, F. Tyers and S. Barnsdale, London.
4319. Foot-pads for Pedestrians, E. H. and A. J. Watson, London.
4320. Eye-glasses, C. Zapp, London.
4321. Combined Belt and Suspender, A. Haynes, London.
4322. Adapting Vehicles to Run on Rails, E. Perrett, London.
4323. Supplying Feed-water to Boilers, E. Petersen, London.
4324. Combined Ruler, E. T. Hughes.—(*E. P. Davies, United States.*)
4325. Air Displacer for Cycles, &c., W. Carr, London.
4326. Armour Plates, J. H. Dickinson, London.
4327. Blotters, J. Temler, London.
4328. Fusing Substances, H. H. Lake.—(*D. N. Maxon, United States.*)
4329. Precipitating Gold from Solutions, W. L. Holms and T. Dobbie, London.
4330. Hand-cords for Staircases, A. Moldenhauer, Liverpool.
4331. Felt Hats, G. Baty and L. Thornley, Manchester.
4332. Water Cocks and Stop Valves, H. Grace, Liverpool.
4333. Joint for Connecting Pipes, &c., T. Crapper, London.
4334. New Toy, T. E. Taylor and J. R. Collings, London.
4335. Fishing Tackle, A. G. Jardine, London.
4336. Non-slipping Boots and Shoes, Z. J. Francis, London.
4337. Driving Gear for Cycles, &c., J. Finlayson, London.
4338. Mechanical Toy, H. H. Fletcher, London.
4339. Knitting Machines, G. F. Grosser and J. Foster, London.
4340. Making Oxygen, G. Munroe and J. W. Kelley, London.
4341. Bracelet Fastening, T. G. Hull, London.
4342. Automatic Guns, H. S. Maxim and L. Silverman, London.
4343. Pneumatic Tires for Vehicles, R. and J. Gibbs, London.
4344. Handle-bars of Cycles, A. J. Boult.—(*C. F. Svendsen, Denmark.*)
4345. Production of Gas, J. H. Dunn and R. G. E. Dalrymple, London.
4346. Pneumatic Tires and Wheels, &c., F. King, London.
4347. Cork Extractor, J. F. O'Brien, London.
4348. Combined Glove and Purse, R. V. Sankey, London.

27th February, 1896.

4349. Charging Cartridges, C. Salmon and H. Bishop, Belvedere.
4350. Imitation Coloured Glass, &c., M. E. Norris, London.
4351. Tobacco Pipes, S. Bott and C. Turner, Birmingham.
4352. Water-tube Boilers, H. McIntyre, Glasgow.
4353. Suspending Trousers to Braces, C. Steer, Bristol.
4354. Two-speed Driving Gear, &c., T. Lambert, Plymouth.
4355. Pneumatic Tires, S. Austin and A. Farnhill, Manchester.
4356. Boiler Tube Stopper, T. Heron and W. Wilson, Newcastle-on-Tyne.
4357. Mud-guards and Chain-guards, W. Liggins, Coventry.
4358. Indicator for Nuts and Screws, H. Ringwood, Dublin.
4359. Steam Engines, J. Holloway, Smethwick.
4360. Hors[illegible]eins Holder, F. Jacks and A. Lazarus, Liverpoo[illegible]

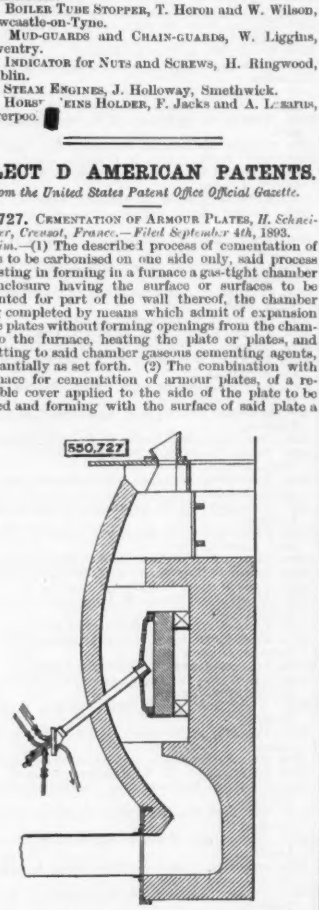
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

550,727. Cementation of Armour Plates, *H. Schneider, Creusot, France.—Filed September 4th*, 1893.

Claim.—(1) The described process of cementation of plates to be carbonised on one side only, said process consisting in forming in a furnace a gas-tight chamber or inclosure having the surface or surfaces to be cemented for part of the wall thereof, the chamber being completed by means which admit of expansion of the plates without forming openings from the chamber to the furnace, heating the plate or plates, and admitting to said chamber gaseous cementing agents, substantially as set forth. (2) The combination with a furnace for cementation of armour plates, of a removable cover applied to the side of the plate to be treated and forming with the surface of said plate a closed gas-tight chamber, and pipes for conveying gaseous cementing agents to and from said chamber, substantially as described. (3) The combination with the cementation furnace, and with the cover or device forming part of a gas-tight cementation chamber in said furnace, of supply and exit pipes communicating with said cementation chamber, and provided with means for regulating the supply and pressure, and with means for preventing deposits of carbon in said pipes, substantially as described. (4) The combination with the cover or device adapted to form part of a cementation chamber, of gas inlet and outlet pipes connected with said cover or device, and a tube or water jacket surrounding said pipes and provided with water inlets and outlets, substantially as described.

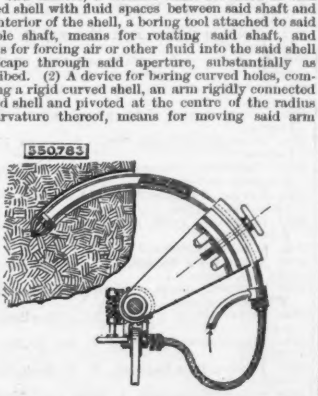
550,727



550,783. Drill for Boring Curved Holes, *R. H. Elliott, Birmingham, and J. B. Carrington, Jasper, Ala.—Filed February 28th*, 1895.

Claim.—(1) A device for boring curved holes, comprising a curved rigid shell, with apertures near the front end thereof, a flexible shaft mounted in said curved shell with fluid spaces between said shaft and the interior of the shell, a boring tool attached to said flexible shaft, means for rotating said shaft, and means for forcing air or other fluid into the said shell to escape through said aperture, substantially as described. (2) A device for boring curved holes, comprising a rigid curved shell, an arm rigidly connected to said shell and pivoted at the centre of the radius of curvature thereof, means for moving said arm about its pivot, a flexible shaft mounted in said shell, a boring tool attached to said flexible shaft and larger in diameter than said shell, and means for rotating said shaft, substantially as described. (3) In a mining drill, the combination with a curved rigid shell, a holder for said rigid shell, pivoted at the centre of curvature thereof, a worm wheel on said holder, and a worm engaging in said worm wheel mounted in said shell, a boring tool attached to the front end of said flexible shaft and larger in diameter than said shell, and means for rotating said flexible shaft, substantially as described.

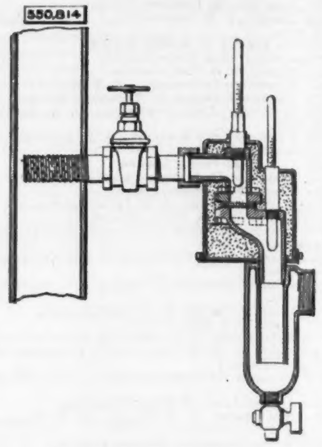
550,783



550,814. Steam Calorimeter, *G. H. Barrus, Boston.—Filed June 14th* 1895.

Claim.—(1) A steam calorimeter comprising a heat measurer or wire drawing device having means for direct connection with a steam service pipe, and a drip chamber or separator attached to the discharge pipe of the said heat measurer, said parts being relatively arranged so that the steam is caused to pass first through the heat measurer and then through the separator, substantially as and for the purpose set forth. (2) A steam calorimeter comprising a heat measurer or wire drawing device having means for connection with a steam service pipe, and a drip chamber or separator arranged to receive the steam after its passage through the said heat measurer, said drip chamber or separator having an adjustable restricted water outlet, and a free steam outlet open to the atmosphere, substantially as and for the purpose set forth. (3) A steam calorimeter comprising a heat measurer or wire drawing device having means for direct connection with a steam service pipe, and a vertical drip chamber or separator arranged to receive the steam after its passage through the said heat measurer and provided with an interior inlet tube extending from its upper end nearly to its lower end, an adjustable restricted water outlet at its lower end, and a free steam outlet open to the atmosphere at its upper end, as set forth.

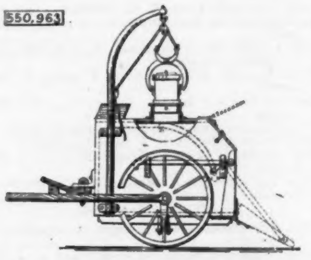
550,814



550,963. Apparatus for Removing Garbage, *W. Goetz, New York, N.Y.—Filed February 2nd*, 1895.

Claim.—(1) An apparatus for removing garbage, comprising a wagon body formed in its upper part with a receiving spout, a davit made in two parts, of which the lower part is rotatively mounted in a vertical position on one side of the wagon body, and provided with bifurcations at its upper part, and the upper part is pivoted at its lower end between the lower portions of the bifurcations of the lower part of the davit, and adapted to be folded down sidewise against the side of the wagon body, and means for holding the upper part of the davit in an erect position when in use, substantially as described. (2) An apparatus for removing garbage, comprising a body having a receiving spout in its top, a slide extending across said spout below the top of the same, and adapted to be removed through an opening in the side of the spout, a box having an open lower end and provided with a projecting exterior flange adapted to rest on the upper edge of the receiving spout, doors hinged at opposite sides of the open lower end of the box, and adapted to fold centrally to close the same, the ends of said doors being arranged to overlap when closed, and a pin removably arranged across said box below said overlapping portions of the doors, and adapted to support the doors in their closed position, substantially as shown and described.

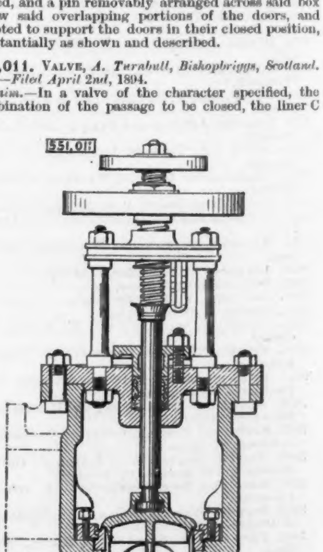
550,963



551,011. Valve, *A. Turnbull, Bishopbriggs, Scotland.—Filed April 2nd*, 1894.

Claim.—In a valve of the character specified, the combination of the passage to be closed, the liner C fitting in said passage and forming a valve seat, and the connections for securing the liner in position, consisting of the fixed lugs E, bolts D, nuts F, and ring *c*, formed on the liner, substantially as and for the purposes set forth.

551,011



RAILWAY ECONOMICS.

No. I.

In the recently published report of the delegation organised by the British Iron Trade Association to visit the Continent, the conclusion arrived at with regard to British and Foreign railway rates is expressed in the following terms:—"Undoubtedly the greatest factor in favour of the foreign producer is the much larger cost of carriage in this country." That such is a fact there is little doubt; and it is probably equally true that this arises from causes which are altogether beyond the control of the railway companies in the United Kingdom. Comprised as they are of a large number of different companies keenly competing for the carriage of the raw materials and manufacturing products, it would indeed be strange if they did not frame their rates on as low a scale as possible, consistent with remunerative business. It will be conceded on all hands that railway companies exist as commercial, and not as philanthropic enterprises; and that the investors in such enterprises are at least entitled to a reasonable return for their expended capital. Here comparison with many continental railways ceases; as, in the case of the latter, State aid and relief are given in various ways, whilst in this country no assistance is in any degree afforded, if we except the contributions towards the light railways of Ireland, which are of so trifling a character that they may be ignored.

It has probably never yet been stated that the railways of this country are not worked as economically as those on the Continent or in America, or that British engineering and administrative skill have to rank as one whit inferior to that of any foreign country. For the purpose of seeing how the financial returns of the United Kingdom stand, we have made a comparison based on the figures supplied by the Board of Trade in July last for the year 1893, as far as they relate to those countries entering strongly into commercial competition with this country. It may be urged that the result in 1895 would be more satisfactory for the United Kingdom, but the increased receipts of to-day are so nearly balanced by the additional expenditure which has had to be incurred, that for all practical purposes matters exist much as they did in 1893.

The progressive development of manufacturing industries has not been confined to one country, and the consequent increased transport receipts may be considered as common to all. If it be admitted that an equitable return should be forthcoming for invested capital, that the working expenditure is judiciously and economically controlled, and if it is found that the dividend result is not higher in the United Kingdom than on the Continent or in America, it would appear that the rates and fares which produce the British receipts are not higher than they should be, having regard to the conditions under which the railways have been established and worked in the various countries. It would be much more satisfactory if the relative earnings of passenger, goods, and mineral traffic could be separately compared; but this is not possible, for, whilst particulars of the separate receipts are obtainable, there are no available data for determining the expense of collecting, hauling, and distributing each class of traffic. The continental railways which have been taken for comparison are Norway, Sweden, German Empire, Saxony, Wurtemburg, Baden, Bavaria, Holland, Belgium, France, and Switzerland, and these are placed side by side with those of the United States and the United Kingdom.

From all that has been frequently reiterated, it would be expected that in the percentage of net receipts to the cost of construction of the several railways, this country would rank amongst the highest; but it is found that, whilst in the United Kingdom it was only 3·6, in Europe generally it was 3·87, in the German Empire 4·34, and in the United States 4·9, and that in Belgium, of which so much has been said and written, the percentage was 4·52. This result clearly demonstrates that British railways have been seriously handicapped by their cost of construction, which per mile of railway was in the German Empire, £20,358; Holland, £22,864; Belgium, £26,611; France, £27,375; or for Europe generally, £21,666, against only £11,343 in the United States, and the high figure of £47,047 for the United Kingdom. It may be contended that much of this abnormal outlay should have been saved, but the money has been raised and circulated here, and has been and continues to be available for the development of other industries, for the carriage of whose traffic a high tariff has become imperative.

The whole tendency of our Imperial and municipal legislation has continuously been in the direction of increased working cost; and the safety, convenience, and expedition of passengers and goods have been amongst the first considerations, not only of the Board of Trade, but of the executive officers of the various railway companies. The vexed question of terminal charges was much in evidence in the recent Railway and Canal Act inquiry, which showed how largely the convenience of the manufacturing public had been considered in this country; and whilst no statistical comparison can be shown as to the relative expenditure for warehouses, crane power, and freight sidings in the United Kingdom with that of the Continent or in America, there is abundant ocular demonstration that in this respect the capital outlay for British railways in this direction has been well to the front. The earnings of any railway company, whether here or elsewhere, primarily rest with its locomotive power; and it will hardly be asserted that modern British locomotives are not equal in haulage efficiency to those on any foreign railway. But even with the higher rates for carriage ruling here, the gross earnings per locomotive per annum is only £4471 in the United Kingdom, against £4358 in the German Empire; whilst in the United States, with longer-paying distances, slower speeds, and consequently heavier-paying loads, the earnings per locomotive per annum are £6992.

Still keeping in mind the higher British rates, it is instructive to find that the earnings of the total rolling stock per vehicle per annum are yet less in this country than elsewhere, the receipts being for the United Kingdom, £123, for the German Empire, £200, and for the United States, £210. The greater carrying capacity of many of the American vehicles explains the high earnings of that country, but the close approximation of the earnings of the German vehicles clearly proves how fully loaded they must have been, compared with the partially loaded vehicles on the lines of this country. Incidentally it may be remarked that much of the success of any development of the proposed light railways for this country will largely depend upon the co-operation of those farming and other industries, in whose interest they are projected, in ensuring as far as possible full loads for each vehicle which is hauled, thereby not only reducing the capital outlay in the provision of rolling stock, but in a still greater degree lessening the working charges incurred in the hauling of trains in which the tare weight of any wagons is double or treble its net or paying load.

The prompt despatch of the partially loaded wagons of the goods of an individual consignee, whilst of considerable advantage to the trader, can only be met by the multiplication of trains, which not only increases the hauling but the marshalling and shunting charges; and this is seen by the number of miles of railway to each locomotive, which in the United Kingdom is only 1·14 miles, against 1·72 in the German Empire, and 4·87 in the United States. Reversing this order, and considering it from the number of miles run by trains over each mile of railway, the necessity for the expenses of train shunting in this country is still more marked; for, whilst in the United States the miles run were only 5069, and in the German Empire 7775, they reached in the United Kingdom a total of 15,637 miles. In consideration of these various points, it is open to question whether the existing rates for conveyance on British railways can, consistently with the lawful interest of their varied ownerships, be brought to a much closer approximation with the charges prevailing on foreign railways, with which their initial expenditure and rolling-stock earnings have been compared.

CORDITE.

Cordite is an intimate mixture of nitro-glycerine, gun-cotton, and mineral jelly, or vaseline. The thorough blending of the two main ingredients is promoted by the addition of acetone, a substance in which both are soluble, during the process of incorporation. The mineral jelly acts merely in the way of restraining the violence of explosion, and serves also to produce a little smoke, which acts usefully as a lubricant to the bore of the gun. The curious effect of the intimate mixture of nitro-glycerine and gun-cotton is to modify their characters and properties altogether. The former substance is an unstable liquid, which decomposes with explosive force on account of the mobility of its molecules; while dry gun-cotton behaves in the same manner because of its highly porous nature, which permits ignition to take place almost simultaneously throughout its mass. Cordite, on the other hand, is a horny substance, which burns only on the surface even under the severe heat and pressure obtaining in guns, as is demonstrated by the fact that partially consumed cords, blown out of guns, retain their shape though reduced often to extreme tenuity. The consequence of this property is that the rate of explosion can be regulated by varying the proportions of surface to volume; thus cords of smallest diameter burn more quickly than the larger sizes, and by slicing up the material into very thin discs, and omitting the vaseline, explosion, having almost the rapidity of detonation, can be produced. It thus becomes easy to adapt cordite to any nature of gun. The service pistol, for example, takes cords of ·01in. diameter, cut to short lengths, forming, in fact, a fine powder; while the new 12in. wire gun takes bundles of cords ½in. in diameter and 14in. long.

Like nitro-glycerine and gun-cotton, cordite is sensitive to heat and light. Exhaustive experiments have shown that it is not expedient to expose it constantly to a higher temperature than 100 deg. Fah., although it suffers no change if occasionally heated as high as 130 deg. Fah. Long exposure to temperatures above 100 deg. Fah. leads, however, to no danger, but may occasion a very slow decomposition of the material, an effect which will show itself in the ballistics obtained from the guns it is fired from; but no change of this nature has as yet been actually observed. The finer the subdivision of the explosive, the more susceptible it naturally is to heat.

Experiments carried on during a whole winter in Quebec have demonstrated that the ballistics are not affected by extreme cold; but experience, even in this country, shows that cordite transferred suddenly from a very cold room into a warm one, will occasionally extrude a minute portion of its nitro-glycerine, which appears as a very light dew upon its surface. But this exudation is gradually reabsorbed as the material gets warm; and in any case it is not a source of danger, nor does it affect the shooting qualities of the material.

Prolonged trials in India have also demonstrated that cordite does not suffer from exposure to the extreme temperatures of a tropical climate, and as magazines can always be arranged not to have a temperature higher than 100 deg. Fah., there seems to be no reason why large quantities should not be stored for a considerable number of years. The occasional exposure to much higher temperatures in the pouches of the soldiers, and the limber boxes of the guns, does not produce any deleterious effect. Direct sunlight quickly turns cordite into a very dark-coloured substance, and diffused light has the same effect only after very much longer exposure. Direct light causes slow decomposition; but sticks exposed for several years to diffused light, though very much darkened in colour, show no measurable chemical change. Owing to the total absence of dust, cordite is a remarkably safe explosive to manipulate. It can be exploded by a severe blow, as, for instance, by striking with a hammer a cord laid on an anvil; in such case the portion immediately under the hammer explodes, but the explosion is not communicated to the cord on both sides of the hammer.

When fired in the open, or even when enclosed in the 100 lb. service cases, it only burns with a fierce flame even when in considerable masses. Thus, a bonfire made round eight cases piled up against each other only fired the contents of the boxes in succession as the wood of the boxes burned away, and not only was there no explosion, but the lids of the boxes were merely forced open enough to let the products of combustion escape. Again, a temporary magazine in which two tons of cordite were distributed on reticulated shelves was kept at 100 deg. Fah. a fortnight and then fired. There was no explosion. The slate roof was lifted off by the rush of gas and deposited on the ground beside the building, no more injured than would be accounted for by its fall; the windows in the brick gables were not broken, and the door had to be unlocked to give access to the firemen.

There is, indeed, some difficulty in igniting cordite even when it forms the charge of a gun, and primings of gun-cotton or black powder have to be used in the case of cannon, while in small arms the percussion caps have to be charged with composition which will give a good flash. When, however, the priming is sufficient, misfires and hangfires are rare.

The volume of the chamber of a gun compared with the weight of the charge is a matter of great importance. On account of the relatively large volume of gases given out and their high temperature, compared with the products of combustion of black powder, the density of the charge must be much less. Solid cordite measures 17¾ cubic inches to the pound, and if fired in a chamber of that capacity would give a pressure of at least 120 tons to the square inch, which would, of course, be destructive to any gun. If a density of 54 cubic inches be assigned, as is the case in some of the larger quick-firing guns, a pressure of 40 tons to the inch might be realised, and is nearly the maximum which can be obtained with black powder; whereas, if, say, 100 cubic inches to the pound be the density, as is the case in many guns, the pressure can never rise above 20 tons to the inch; consequently it is found that in guns with high density charges the pressure and velocities are much affected by climatic changes, and by the conditions of the bore and of the shot. But even under such unfavourable conditions of density, the regularity of shooting is quite equal to that obtained with black powder.

The diameter of the cords is proportioned to suit the bore of the gun, the capacity of the chamber, and the length of travel of the shot. Up to the present the sizes made range from ·01in. diameter for the service revolver to ·5in. diameter for the new 12in. naval gun.

With respect to erosion, it may be said that it certainly is not greater than that arising from the use of black powder, and it is of a much more favourable kind. Black and brown powders scoop out and plough rough, irregular channels in the bore, whereas cordite appears to wash away the surface in a uniform manner. This effect is probably due to the absence of solid or liquid particles in the products of combustion, and to the presence of a large proportion of carbonic oxide at a high temperature. The erosion extends for only a few calibres along the bore, and owing to these circumstances expanding gas checks on the driving bands of the shot enable the gun to shoot well longer than when powder is used. It should be borne in mind also that the ballistics obtained by the use of cordite are very much higher, as a rule, than with black powder; in the case of the 12in. naval gun, for example, the energy imparted to the shot is 1·8 times greater than in the old service gun, consequently increased wear must be expected.

The manufacture of cordite is extremely simple. The nitro-glycerine and the dried gun-cotton are mixed together in accurately weighed proportions. The liquid is poured over the gun-cotton, and mixed with it by hand till the nitro-glycerine is completely absorbed, and the resulting mass looks like a quantity of dirty white moist sugar. This mass is then placed into kneading machines with a proper proportion of acetone, and is incorporated for three and a-half hours, when about 5 per cent. of vaseline is added, and the kneading continued for another three and a-half hours. The mass then becomes a stiff dough, not unlike raw Jamaica sugar in appearance, and about the same colour, and is ready for squirting into any size or form that may be needed, for unlike the old powders, the composition of cordite is the same in every variety of size produced.

The squirting machines consist simply of vertical cylinders of various sizes, into which the dough is placed. They are fitted at their lower ends with one or more removable dies, and provided with pistons actuated by screws or by hydraulic cylinders. In the former case the pressure of the screw is transmitted through a hydraulic cushion which gives the means of noting the pressure and also of relieving it when excessive. For the small sizes used in rifle ammunition, the cords are wound automatically as they issue from the dies on to reels holding about 1 lb. each, these are blended together in tens on to a single reel, and six of the latter are combined on one reel, from which the sixty strands are fed into the cartridges. The larger sizes are either wound by hand on to reels, whence they are cut off in lengths, or they are delivered by the press on to an endless band to which knives are fastened at the required distances. The cord lies over the knives, which passing under a small roller cut through the cord, and leave it ready to be picked off by boys, and arranged in shallow trays. The small-arm reels and the trays of cut cord are placed in stoves, in which they are dried by exposure to currents of air warmed up to 100 deg. Fah., and in this process all the acetone is driven off. When dry the cut cords, like the cordite on reels, is blended so as to make uniform samples.

The danger of the manufacture is confined to the production of the nitro-glycerine and the drying of the gun-cotton. As soon as the two explosives are mixed together they appear to be incapable of explosion, except when confined in a gun. At Waltham Abbey, some years ago, a gun-cotton drying stove caught fire, from some cause which has never been ascertained, as there was no one near it at the time. The material was perfectly dry, for the stove was just going to be emptied, yet there was no explosion and no one was hurt; the fire was, however, exceedingly fierce, and any one in the stove would certainly have been destroyed. The accidental explosion of a large quantity of nitro-glycerine, though attended with lamentable loss of life, also showed that the damage done was very local, apparently much more so than the destruction which a corresponding quantity of black powder would have produced. We have very little doubt but that fuller experience will show that our War Department has made a wise selection in adopting cordite as the explosive best suited for our guns.

MECHANICAL ENGINEERS' ESTIMATING.

In these days of competition and mechanical progress engineers' estimating—especially with firms of moderate size manufacturing stationary engines and boilers for land use—is not the comparatively simple matter it used to be in days gone by. Then if a customer wanted, say, an 8-horse power portable, he said so; and it did not require very much knowledge on the part of a clerk to pick the correct price from the firm's price list, and send a quotation. If the inquiry was not quite so straightforward, the partners talked the matter over at their leisure; perhaps consulted one or two of their foremen, and a price was arrived at without going into any very abstruse calculations over the matter. We have even heard that in cases where the machinery required was of anything like a special nature, it was not always the custom to quote a price beforehand; but the purchaser had to wait until he received an invoice worked up from the actual cost, after delivery of the goods. This was no doubt a very sensible, if not a very satisfactory, mode of procedure, but, for all that, would hardly satisfy present day customers.

These methods are no longer in vogue; they have been found inadequate. Inquiries of the 8-horse power portable nature are in the minority, and are not thought so much of as they used to be; whilst those requiring careful consideration and long calculations represent the greater portion of modern work. It is only necessary to read through a printed official specification for the electric lighting of some town or district, with the numerous schedules and conditions attached, to get some idea of what modern engineers' estimating is, and to realise the responsibility that rests with the estimating clerk.

It will be inferred from the foregoing that an estimating clerk, if he wishes to get on, and to discharge his duties well and quickly, which latter qualification is most essential, must, besides his commercial training, have a very fair technical knowledge, and be thoroughly well acquainted with the construction of the machinery turned out by the firm he happens to serve. He must also be able to read drawings, and run out quantities from them; and in short, exemplify the somewhat unique combination of an engineer, a draughtsman, and a commercial man well versed in all the wily ways of the mercantile world. In many cases the estimating clerk has in addition, the responsibility of inditing and supervising the specifications sent out with his estimates, so that he must be able to describe correctly and concisely the machinery for which he is tendering.

As regards the system of estimating, and the books kept in connection therewith, no precise rules can be laid down. This will depend upon the nature and extent of the work turned out, and upon various other considerations. However, a few general remarks on this point may be useful. It is a very convenient thing to have two separate estimate books running at the same time; one a general book, in which all estimates made upon the basis of charging prices taken from standard price lists are entered; and the other a special book, in which are booked such estimates as are worked up from the prime cost of materials and labour. Of course a note should be made in the general of all entries in the special book for convenience of reference, so that the former will serve as a daily record, or journal, of all estimates submitted.

The following example of the working of this system will make matters clear:—Suppose a compound vertical engine of 200 indicated horse-power is being quoted for; and presuming it is a standard engine, for which there is a fixed charging price, or, at any rate, so near a standard size that a charging price can be arrived at by comparison, the entry would take something like the form of the tables in the next column.

The entry in the special book would be of a more complicated nature than in the case of the vertical engine. To begin with, the heading of the estimate should contain all the principal particulars of the boiler, including heating surface, grate area, thickness of plates, &c., for future reference; then would follow a list of all the materials used in the boiler, such as plates, rivets, angles, bars, tubes, &c., with the weight appended to each item of the list, with the exception of the tubes, against which should be placed the total length required. The costs of these would be run out at so much per ton or per foot run, giving the total cost of materials used in the boiler; the cost of making would then be added, and finally the cost of the fittings and cost of putting them on. The total estimated cost in the shops would thus be arrived at, and the estimate completed by adding for trading expenses, cost of carriage, and last, but not least, the profit.

On whatever system the book-keeping of the estimating department is carried out, it should be one giving every facility for ready reference. The estimating clerk will find it very convenient to have two indices to his books, one for the names of the firms quoted, and the other wherein to note any special machinery the price of which might be useful to him for future estimates. As an example, suppose a quotation is sent to Jones and Co. for a triple expansion vertical engine of unusual size; then in the first index under J the name of the engineers would be indexed, and in the other, under S, would be noted the size of the engine in question, with reference to the page where the estimate would be found. This will, no doubt, appear a small matter, but when all his books for years past are indexed in this manner, the estimating clerk will find them wonderfully useful works of reference when getting out fresh estimates.

1895.

Dec. 2	Brown and Co., Ld., Hull.	Rate.	£	s.	d.	£	s.	d.
	One compound vertical engine, 15in. and 26in. by 24in., 200 I.H.P., 100 revols., 130 lb. initial, condensing, fly-wheel 12ft. diameter, outer bearing		—	—	—

The next entry might be as follows:—

1895.

Dec. 3	Robinson and Co., Liverpool.							
	One marine return-tube boiler, 7ft. diameter by 7ft. 6in. long, 160 lb., Lloyd's rules. For details see page 300, Special Estimate Book No. 8				£	—	—	—
	Terms of payment							
	Time named for completion of order							

It is more usual to work up boilers in detail than engines, for the simple reason that the quantities of a boiler can be readily run out from a drawing, and the cost of manufacture is easily got at, being practically confined to one shop; whereas in the case of an engine, the drawing will take a considerable time to prepare in the first instance, and getting out the quantities and cost of making is no small business, on account of the variety of materials used, and the number of shops through which an engine has to pass. When time is short—and this is more often the case than not—it will be found very useful to take the prime cost of similar machinery and see how much it runs out at per ton; then estimate as near as possible by comparison and judicious use of the rule-of-three the weight of the new work, and run out at the same or a proportionate rate. It is necessary, however, to be very careful, especially in estimating for engines in this way, as some extra fittings or difference in design may easily make the cost of the engine taken as an example come out considerably more per ton than it would in the ordinary way. The estimating clerk should make it a rule to compare his estimated prices as often as possible with the prime cost. No matter how carefully or at what length an estimate has been prepared, it can never be taken as a perfectly sure precedent; while the prime cost being based on hard fact, and not conjecture, is generally a pretty sure point to start from.

There is another matter well worthy of consideration, especially in these days of specialities in steam fittings, metallic packings, steam traps, and such like; and that is, the estimating clerk will find it necessary to have by him a large quantity of price lists in order to be able to deal at once with inquiries comprising some such speciality. Now, even a moderate collection of lists of the nature above referred to means a good deal of paper, and, if not arranged according to some system, the lists are practically useless for ready reference. A set of pigeon holes in which they can be placed in alphabetical order, will be found useful; and a scrap-book, in which the more commonly used lists, say, of pulleys, belting, tubes, &c., can be pasted, will be found most convenient. In this book each list should of course be numbered and indexed for easy reference, and any notes concerning same could be made on the blank pages.

Besides his systematically arranged tables of prices, which are a *sine quâ non* to him, the estimating clerk should have a properly arranged dimension book, with all possible details and dimensions of the machinery made by his firm. He should leave ample space in this book in which to note results of engine and boiler trials, particulars of special machinery manufactured, and a thousand-and-one little details, which are sure to be of use some time or another; for although the estimating clerk is not in the ordinary course of things called on to decide upon technical matters of moment, yet he very often has to settle technical details of less importance, and he can never tell, when, through the absence of some of his chiefs, he may be called upon to give his decision in matters of consequence.

Finally, it will be seen that the post of estimating clerk is a very responsible one, as on him depends to a great extent whether the firm obtain orders or not, and if obtained, whether sufficiently profitable or not. In fact, the success of a growing firm of engineers will often depend to a considerable degree on the ability and knowledge of the man who rules the destinies of their estimating department.

THE PADDLE STEAMERS KONINGIN WILHELMINA, KONINGIN REGENTES, AND PRINS HENDRIK.

The Fairfield Shipbuilding and Engineering Company, Limited, of Glasgow, has recently built and engined the three above-named swift steel paddle steamers for the Zeeland Steamship Company, to take part in that company's admirable passenger service between Queenborough and Flushing. Our illustrations show in elevation and plans the form and arrangements of these fast and commodious steamers, as well as the general appearance of their powerful engines, as viewed from the after-end of the engine-room.

The principal dimensions of the Koningin Wilhelmina and her two sisters are 320ft. by 35ft. 6in. by 24ft. deep to the uppermost or awning deck. The hull is in each case carefully subdivided into water-tight compartments by eight steel bulkheads efficiently stiffened, which extend to the main deck, as well as several other bulkheads reaching as high as the lower deck. Ample provision has, therefore, been made against such a contingency as one or more compartments being penetrated by collision. The materials in the structure have also been most judiciously distributed in order to provide the greatest strength where it is most needed and to have a sufficiency everywhere. All the supports to engines and boilers have been given the form of continuous longitudinal girders, and by effectively incorporating them with the framing and plating of the hull proper they have been enabled to form the double purpose of keelsons and of engine and boiler bearers. Special attention, too, has been given to the construction of the massive entablature supporting the crank shafts, which is attached to a thick transverse bulkhead, and supported by a series of vertical girders that act as web stiffeners to the bulkhead. In view of the great engine power this was a wise arrangement, and the massing of so much material at that part of the vessels has been amply justified by the freedom from vibratory movement experienced when running at their highest speeds.

Of course, the Fairfield Company had the advantage of considerable experience of the Zeeland Company's requirements, having previously contributed no less than seven steamers to its excellent fleet. It happens that for a considerable fraction of the total distance of 110 knots separating Queenborough from Flushing the steamers are in shallow water, and consequently the resistance to fast steaming is greatly increased at that part of the route. The drag upon a vessel in shallow water is, of course, so great that it practically fixes a limit beyond which fast steaming is impossible. The object in view with these vessels was to cover the 110 knots in about six hours; but to do this it became necessary to attain, if possible, a speed of 21 knots in the deep water of Wemyss Bay, where the preliminary trials were run. The builders were so far successful in their efforts that in each case the 21 knots were slightly exceeded, the mean result being about 21¼ knots per hour. With this deep-water speed in them, the vessels have been enabled to fulfil their requirements on the Queenborough and Flushing route.

As will be seen by our illustration, the engines supplied to these vessels are triple expansion, diagonal, surface condensing, and their three cylinders are placed side by side to work a three-throw crank shaft. They are, in fact, the most powerful triple expansion engines fitted to any paddle steamer yet afloat. The Zeeland Company adopted this style of engine in the new vessels with a view to maintaining the reputation they already enjoyed among the travelling public for affording smooth and easy motion without vibration when running at a high speed, and at the same time to secure economy of fuel consumption. The cylinders are 51in., 75in., and 112in. in diameter, with a 78in. stroke. The high-pressure cylinder has a piston valve, while the intermediate and low-pressure cylinders each has a flat slide valve, all being worked with the usual double excentrics and link motion valve gear. Both the crank and paddle shafts are of mild steel manufactured by Sir Joseph Whitworth and Co., the crank shaft being connected to the paddle shaft by flanged couplings and bolts. Between the cylinders and the supports for the crank shaft the condenser is placed, which is of cylindrical form and constructed of boiler plate, the necessary condensing water being supplied by a large centrifugal circulating pump worked by two independent steam engines. A feed heater, feed filter, an evaporator, and all other such modern appliances are also provided in the engine-room. The starting and reversing of the main engines is effected by a steam and hydraulic reversing engine. The whole of the paddle-wheels, including the floats and feathering gear, are of Siemens-Martin steel, and the floats are formed with a curved surface.

There are two stokeholds in the vessels, one before and one abaft the engines. In each stokehold there are three large single-ended boilers of the ordinary "Scotch" type, and fitted with forced draught. As each boiler has four furnaces, there are consequently twenty-four furnaces in the vessel. The working pressure is 170 lb. per square inch, and the horse-power upwards of 9000 indicated.

Being for cross-channel passenger service, and intended for a run of about six hours, one would suppose that the accommodation provided would for the most part be that of a daylight trip. This is to some extent the case; but, nevertheless, the state rooms afford sleeping accommodation for 180 first-class passengers and 72 second-class, the former being berthed at the after, and the latter at the fore part of the vessel. The full accommodation for passengers is provided on three decks. At the after part of the uppermost deck is a large deckhouse, at the middle portion of which is a spacious entrance for first-class passengers, this part being framed and panelled in teak and maple. A very large state room, framed and panelled in mahogany of different shades of colour, and most elegantly fitted, with a view to being used by distinguished or titled personages, communicates with this entrance, as also do four deck cabins. The remainder of the after deckhouse contains the smoking room, two deck cabins, and the "well" for light and ventilation to the dining saloon. The upper deck entrance opens to a large stairway leading to the main deck, where are situated the dining saloon and the ladies' cabin. The former is framed in mahogany and satinwood, the panels being pictures specially painted for the purpose by Dutch artists. The ladies' cabin has panels of lincrusta-walton, with framing coloured in delicate tints. A corridor extends aft from the dining saloon, framed and panelled in teak and maple, having passages on each side leading to the first-class sleeping cabins, the most of which are situated here and immediately below on the lower deck. At the forward part of the upper deck is another deckhouse, having an entrance which leads to the second-class accommodation, consisting of a dining saloon and ladies' cabin on the main deck and an apartment on the lower deck fitted up with berths or sofa beds.

On the starboard side of vessel forward are built a large mail-room and post-office, the latter being fitted with sorting table, racks, and pigeon-holes complete, for the sorting of letters *en route*. An adjacent apartment is provided for the mail officer. Everywhere in the vessel provision is made for heating with steam, and the details for ventilation have been most carefully and satisfactorily attended to. It need hardly be said that there is also an installation of electric lighting provided. Hold space is provided for cargo, and steam winches fitted for loading and discharging the same. Steam pipes for extinguishing fire are fitted in the holds. Both hand and steam steering gear are provided, also a steam capstan windlass forward, and a steam wharfing capstan aft. Six boats are hung in the davits, and all the other life-saving appliances provided, as required by our Board of Trade. The vessels have been specially surveyed during construction by Lloyd's surveyors for the A1 class for Channel service.

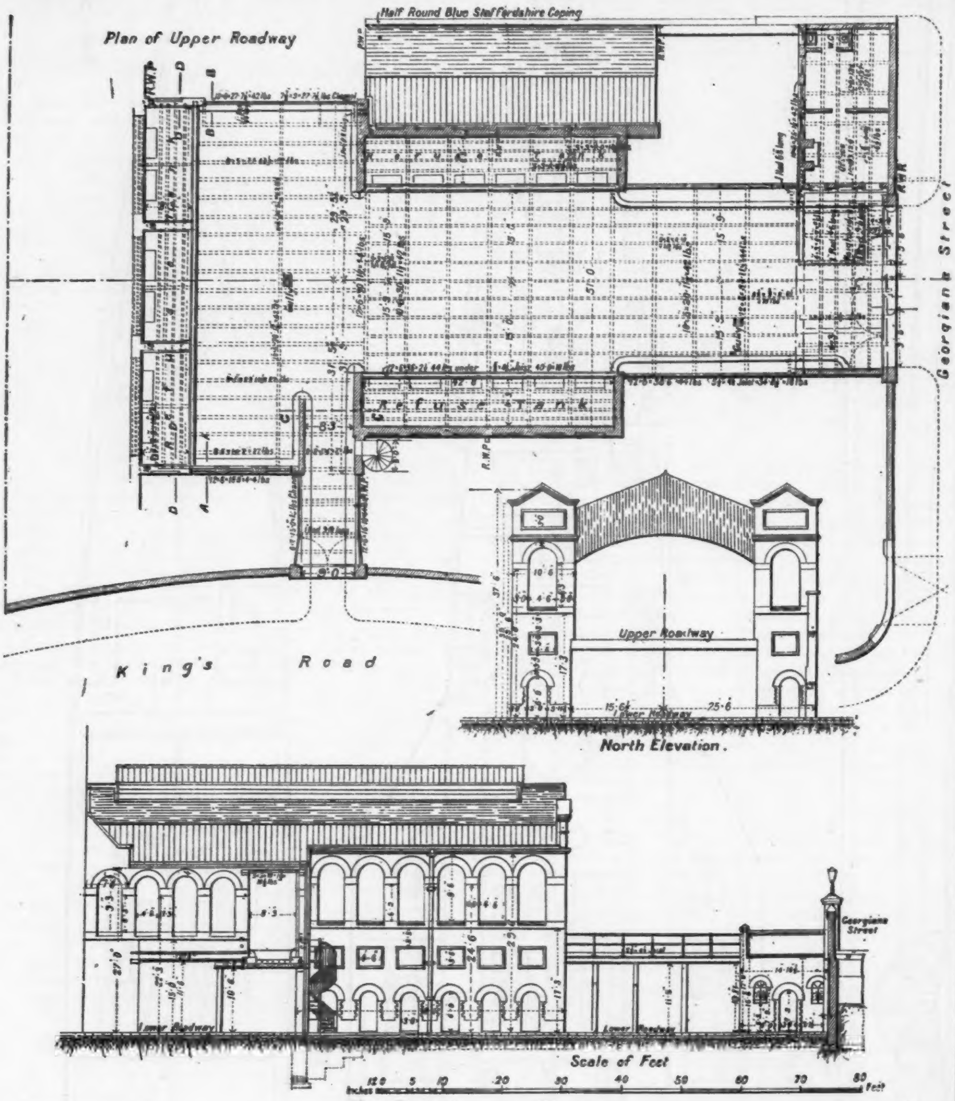
"THE ENGINEER"

SWAIN ENG

ST. PANCRAS ELECTRIC LIGHTING.

THE KING'S-ROAD REFUSE DESTRUCTOR AND ELECTRIC LIGHTING STATION.

During the last two years the St. Pancras Vestry have been constructing at King's-road, Camden Town, works which have a special interest to municipal authorities, as they combine two of the most important operations which devolve upon local authorities, namely, the destruction of dust-bin refuse and the generation of electricity for public supply. The works are erected on the same site, and the two operations can be carried on either in conjunction with one another or quite independently.



"The Engineer" East Elevation Fig 1. Swain Eng.

The question of the disposal of the dust-bin refuse in St. Pancras by means of destructors was under the consideration of the Vestry as far back as the year 1876, and for several years the matter was investigated by a special committee under the chairmanship of Mr. Nathan Robinson. In 1891 the late chief surveyor, Mr. Booth Scott, reported to the Vestry on the cost of the disposal of the refuse and road sweepings during the preceding ten years, and in that year the proposals that had been often made that the Vestry should take into its own hands the disposal of the refuse of their district assumed a definite shape, and a committee was authorised to proceed on those lines. At this time the Vestry had carried out an installation of electric lighting under Professor Robinson—as illustrated in The Engineer, vol. lxxiii.—who suggested, in view of the large demand for electricity throughout the district, that a combined electricity and refuse destructor station could with advantage be carried out for the purpose of utilising the waste heat from the destructors in connection with the boilers to generate electricity. Professor Robinson and Mr. Wm. Nisbet Blair—the then newly-appointed borough engineer—recommended early in 1893 the carrying out of a joint installation at King's-road, and a special committee — of which Mr. Dixon was the chairman — advised the Vestry to adopt this recommendation, and it was approved, a special committee being appointed to carry it out, of which Mr. Lamble was chairman. In this connection mention should be made of the late Mr. T. Eccleston Gibb, who, as vestry clerk, took a leading part, both in supporting this scheme as well as in preserving the supply of electricity as a municipal enterprise in the hands of the Vestry.

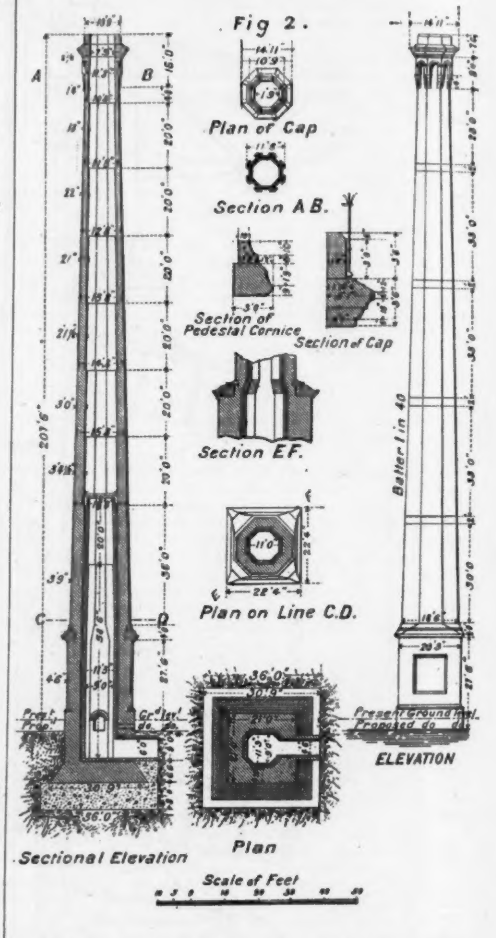
Scale of Feet
Inches 12 0 1 2 3 4 5 6 7 8 9 10 20 30 40 50 Feet

The site purchased by the Vestry for the combined works covers an area of 28,000 square feet, but the present works only occupy about 24,000 square feet; the remainder—being under leases not yet expired—will be available for ultimate extensions of the electricity works. There are frontages on three sides of the site at different levels, which are particularly convenient for dealing with the dustbin refuse and the clinker from the destructor furnaces. Fig. 1 shows the general arrangement of the works.

The north frontage is in Georgiana-street, at a high level affording access for the dust carts to the top of the furnaces. The south frontage is at a lower level, and provides an entrance with a short inclined roadway to the destructor yard, and also a level entrance to the engine and dynamo house. The east frontage is in King's-road, and is utilised for an exit for empty dust carts and for an entrance to the electricity works coal store. A subway 50ft. long, 11ft. wide, and 10ft. high, under Georgiana-street on the north connects the works with Bangor Wharf on the Regent's Canal.

A chimney shaft 207ft. 6in. in height—Fig. 2—was constructed to serve both for the destructor station and for the electricity installation, Messrs. Kelly Bros., of Liverpool, being the contractors.

The shaft stands upon a concrete foundation 36ft. square and 8ft. in thickness, resting upon the London clay at a depth of about 23ft. 6in. below the ground surface. From this base the shaft rises square to form a pedestal 21ft. wide each way, the brickwork of which is 4ft. 6in. in thickness. From this pedestal an octagon shaft is carried up to an ultimate height of 231ft. above its foundation. The shaft is built with stock bricks and Ruabon red brick quoins and strings. The capping is formed of Derbyshire stone, three courses in depth and eight stones in each course, which are all cramped together with copper cramps. For a height of 80ft. from the bottom of the flue the shaft is lined with firebrick, between which and the main structure a 3in. cavity is left, ventilated with openings from the outside, to prevent the heat being communicated to the main brickwork of the shaft. The diameter of the flue is 9ft. at the base and 7ft. 9in. at the cap.



The main block of destructor buildings is 80ft. in length by 51ft. in width, and 30ft. above the ground to the eaves, forming two stories, the lower one containing the furnaces and the refuse tanks, together with passages between them giving access to the furnaces, the upper storey consisting merely of a paved roadway 30ft. wide, by which the vans bringing the refuse have access to the refuse tanks, one of which is situated on each side of this roadway, and three smaller tanks at the south end of the block. The roadway is on a level with Georgiana-street, and at the entrance is placed a 10-ton weighbridge, by Messrs. Avery and Co. An additional exit for the empty vans is provided on the east side, leading down a short incline to King's-road.

The destructor plant consists of eighteen furnaces, together with the necessary flues, both above ground and under ground, to conduct the hot gases where required, and eventually to the chimney shaft. It includes also the refuse tanks and provisions for all the machinery required in the depôt. This work was carried out by Messrs. Goddard, Massey, and Warner, of Nottingham.

Six furnaces are placed on each side of the main building and under the upper roadway, and six more are placed in pairs at the south end of the block, all the furnaces being connected to the refuse tanks by iron hoppers, by which the refuse passes from the tanks to the back of the furnaces. The form of construction of the furnaces is not that to which Messrs. Goddard, Massey, and Warner's name has been attached for some years, but is a design of the borough engineer's—see Figs. 3, 4, and 5—based upon examination of various forms of furnaces. He has aimed at avoiding disadvantages in other arrangements, and in securing as far as possible the greatest efficiency in the working of the furnaces by consuming as much refuse as possible without causing a nuisance, and in producing a continuous high temperature.

He also avoids as far as possible the manipulation of the refuse in the fires, by the adoption of the Healey mechanical stoking fire-bars. The principal points with reference to these are—that every alternate bar moves continuously upon a cam shaft at the back end of the cell and slides on a dead plate at the other end, the object being to carry forward the refuse at a rate found suitable to the consuming capacity of the furnace. Into these bars there are coupled—by knuckle joints—shorter bars at a steeper inclination, and placed at the bottom of the hoppers. These bars also assist in carrying the material forward to the furnaces. The intermediate bars of both the front grate and the back grate do not move.

The moving fire-bars of twelve cells are operated by shafting from the engine-room, where the source of power is a 24 indicated horse-power Chandler's silent engine, which also drives two mortar mills and a stonebreaker for breaking up into macadam any old granite setts that are unsuitable for redressing. The remaining six cells at the south end are served by a small donkey engine.

The engine-room also contains two small vertical engines of Goddard, Massey, and Warner's make, provided to drive separately two Sturtevant blowers, which supply forced draught to twelve furnaces. These blowers are set below the floor level, so that the delivery from them may pass in a straight line to 18in. pipes laid underground without any bends. The air is supplied to the furnaces by means of ports on each side of the ashpits, the ports being provided with shutters to stop the draught during the process of clinkering the furnaces or clearing out the ashpits.

Professor Robinson completed the first electric installation in 1891, and the Vestry commenced the supply of electricity in November in that year, when they opened their first central station at Stanhope-street, Regent's Park. A description of this appeared in The Engineer of February 19th and 26th, 1892. The district supplied then extended from Oxford-street to Park-street, and from Regent's Park to Tavistock-square. The electricity was distributed on the continuous current three wire system, at 110 volts, or 220 volts across the outer conductors. It was always intended that the northern and eastern portions of the parish should at some future time be supplied from one or more additional generating stations, and the King's-road station just completed is in conformity with this. The general outline of the scheme was indicated in two joint reports by Professor Robinson and Mr. Blair, issued in February and March, 1893. The principle of the scheme having been approved by the Vestry, a sub-committee was appointed to consider where the new mains should be laid, and what their capacity should be. This sub-committee took a broad and comprehensive view of the matter, and presented a report advising that provision should be made for supplying 10,800 lamps of 16-candle-power simultaneously in use, distributed over an area extending from Guilford-street, Gray's-inn-road, to Highgate-road, a distance of over three miles, or 2700 yards in either direction from the King's-road site. In July, 1894, Professor Robinson presented a report, in which he recommended that, in view of the large area to be served, and the demand to be provided for, it would be best to develope the three-wire system into the five-wire system, and to distribute the current at 440 volts instead of 220, as in the original scheme. This was adopted, and the works have been carried out on those lines.

ST. PANCRAS ELECTRIC LIGHTING-MAP OF AREA SUPPLIED

Figs. 6 and 7 show the arrangement of buildings containing the generating plant. The contractor for the buildings was Mr. J. O. Richardson, who also erected the destructor buildings, with the exception of the underground condenser water tank, which was constructed by J. W. Killingback and Co. under a separate contract. The tank measures about 53ft. by 32ft. in plan over all, and 20ft. 3in. in height. The depth of water is 16ft., and the capacity 115,000 gallons. The tank was built before the chimney in order to avoid deep excavations near the base of the latter. The covering of the tank is a coke breeze concrete floor 1ft. thick carried on rolled steel joists arranged to suit the flues above. Sections of the tank appear in Figs. 5 and 7.

(*To be continued.*)

THE TUNNEL UNDER THE THAMES AT BLACKWALL.*

By Mr. Alexander R. Binnie, M. Inst. C.E.

During the past ninety years many proposals have been made for crossing the Thames below London Bridge, where the port of London, with its river, ships and docks, forms a barrier to vehicular or pedestrian traffic between its opposite banks. The first work of the kind attempted, but not completed, was Vayes' tunnel at Limehouse in 1805. We then have Brunel's tunnel, 1825 to 1841; then the Tower Subway for foot passengers, 7ft. in diameter, carried through the London clay, in 1869-70, by Messrs. Barlow and Greathead; and finally, the late Metropolitan Board of Works obtained an Act in 1887 to construct a tunnel under the Thames at Blackwall, six miles from London Bridge. This tunnel crosses the river one and a-half miles below Greenwich and three miles above Woolwich, and will bring these growing and populous places into direct communication with Poplar and the East and West India Docks on the north side of the Thames. The section of the tunnel—see diagram No. 2—shows that at this point the river is 1200ft. in width and 46ft. in depth at high water; and borings revealed the fact that although the London clay was present on both banks of the river, yet that the tunnel must pass below it into the sands and clays of the Woolwich series, and for a considerable distance through a bed of gravel which apparently filled an older and deeper river bed. Not only had the river to be passed under, but it will be noticed that it is unbanked, and that what were the old marshes on each side are below the level of high water in the river. Further, it will be observed from the section that the soil of these marshes, to a depth considerably below that of low water in the river, consists of vegetable soil, peat, sand and gravel, all of them highly charged with water. Under this is the London clay with its base beds of impure limestone full of fossils, and then the sand, clays, &c., of the Woolwich beds. All these beds were under the full pressure of water due to the varying tidal level, and in their natural state so saturated were some of the beds of sand as to connect them with quicksands.

But undoubtedly the most serious obstacle was the large deep bed of coarse gravel with but little sand. This gravel was open and fully saturated with the river water, and as the bottom of the tunnel was to be 80ft. below high water, it was certain that a pressure of about 35 lb. on the square inch would have to be encountered. This, however, was not the only difficulty, for it was clear that if the water could find an easy entrance to, and flow among the gravel, air would also as easily escape from it. It was obvious therefore from the outset that the tunnel would have to be constructed under difficulties never before contended with either in the construction of Brunel's tunnel at Rotherhithe or elsewhere. Moreover, it was evident that no ordinary mode of tunnelling could be adopted, and that some description of shield would be required.

Again, from the difficulties met with by Brunel at the much easier site at Rotherhithe, that some more than ordinary measures would have to be resorted to to keep out the inflow of water in passing under the river, and through the gravel bed above referred to. It was consequently determined to use compressed air, as had been first suggested in his patent of 1830 by Admiral Lord Cochrane—Earl Dundonald—and which had been successfully used under Lake Michigan and the Hudson River at New York, as well as at the tunnel under the Saint Clair river, and on a portion of the City and South London Railway at Stockwell. After consultation with Sir Benjamin Baker, and Mr. Greathead, the final design was determined upon, and the contract was let by the London County Council to Messrs. S. Pearson and Son for £871,000 early in 1892. The whole work is 6200ft. in length, the incline on the south or Kent side of the river is on a gradient of 1 in 36, and has a run of 2408·6ft.; the portion under the river for a distance of 1212ft. is level, and the north or Middlesex incline has a gradient of 1 in 34 for a length of 2579·6ft. In other words, the inclined approaches will not be so steep as parts of St. James'-street and Regent-street, and very much less so than the east side of Trafalgar-square, opposite Morley's Hotel; they will, however, be about equal to that of the Haymarket. The work may be divided into three portions—open approaches with side walls, cut and cover arched over with brickwork, and tunnel proper composed of cast iron rings lined and concrete faced with white glazed tiles, all the other parts of the work being faced with white glazed bricks. The lengths of the various portions, including the shaft, are as follows:—Open approach, 1735ft.; cut-and-cover, 1382ft.; cast iron tunnel, 3083ft.; 6200ft., or a total of a little over one mile. To facilitate the work, so as to permit of altering its direction, which it would be difficult to do by means of a long curve in a tunnel of this description lined with cast iron, and to secure ventilation, there are four shafts, varying in depth from 75ft. to 98ft., and having an internal diameter of 48ft.

The tunnel proper is circular, in cross-section 27ft. outside diameter, or 6ft. larger than that of St. Clair—the largest hitherto constructed—built up of fourteen cast iron segments and a key-piece; each complete ring of segments is 2ft. 6in. in width. The thickness of the cast iron is 2in., the flanges are 12in. deep, measured from the outside, and each segment weighs about one ton. All the joints are brought to a true and even surface by machine planing, and the whole are bolted to each other and to the adjacent cast iron rings by wrought iron bolts and nuts. To ensure that the cast iron plates have a firm abutment upon and against the surrounding earth, there is a hole near the centre of each fitted with a screw plug, through which grout is forced, as will be presently described. The internal edges of the flanges of the plates for a depth of 2in. are recessed, and after they are fixed in position and bolted together, this recess is filled and caulked with rust joint cement, composed of iron filings and sal ammoniac. The space between the flanges, and for a distance of 4½in. beyond and around them, is filled up solid with Portland cement concrete, faced with white glazed tiles, so that the effective diameter of the tunnel is 24ft. 3in. Within this the road of 16ft., with two footpaths each 3ft. 1½in. in width, is formed, resting on an arched subway 12ft. in width and 5ft. 6in. in height, for the reception of water pipes. There are also proper drains for the road and channels for smaller pipes for road cleansing, &c. This road of 16ft. will be of the same width as parts of Little Queen-street, Holborn, and King-street, Westminster, and of a greater width than parts of Drury-lane, Fetter-lane, Upper and Lower Thames-street, London Wall, Lombard-street, and Threadneedle-street, and as there will be no occasion for stopping at shops, houses, and street corners, it should be ample for two lines of the largest vehicles. Should the traffic, however, increase beyond the capacity of the tunnel, land has been secured for the construction of another and parallel line of tunnel. The road will be paved with asphalte in the level portion under the river and with granite laid in tar and pitch on the inclined approaches. The whole work underground will be lighted by three rows of incandescent 32-candle power electric lamps, placed alternately 10ft. apart on the common centre line, no gas being admitted to any portion of the tunnel.

---

* Discourse, Royal Institution of Great Britain, Friday, 6th March, 1896.

The cut-and-cover portions of the work are formed of brickwork varying in thickness from 18in. to 2ft.; this is covered with 1½in. of asphalte, and backed with 2ft. of Portland cement concrete, so that the thickness at the thinnest part is 3ft. 6in. Internally the cut-and-cover portions will in all respects resemble that of the tunnel proper formed in cast iron. The open approaches as above described are flanked with inclined retaining walls faced with white glazed bricks carrying a high fence wall with stone coping.

At each extremity the tunnel will be approached through an arched gateway supporting the lodge-keeper's house; there will also be stairway access at the junction of the open approach with the cut-and-cover, as well as stairways down one of the shafts on each side of the river; the other shaft near the river on the south side being in private property, is domed over and a ventilating chimney carried up from it; the similar shaft near the river on the north side being devoted to administrative and working purposes, such as pumping, elevating, lighting, &c. Each shaft is of the shafts so as to prevent the floors from being blown upwards under an air pressure of 4000 tons.

I think that I have now in its main outlines described the principal features of the work, and must proceed to give some account of the mode of its construction. In doing this I shall have first to describe the shield, and then the mode of working it under compressed air—*see* THE ENGINEER, 27th December, 1895. The shield as shown on the diagrams and in the model on the table is a structure of steel, cylindrical in shape, 19ft. 6in. in length and 27ft. 8in. outside diameter. It is stiffened by two circular partitions 3ft. apart, and its forward or working face, which presses against the material to be excavated, is divided into twelve pockets or cells by three horizontal and three vertical partitions. It is within these spaces, which are 6ft. in height, that the men work. Between the two circular stiffening partitions are formed air locks and shoots for passing out the excavated material. Arranged round the inner circumference of the shield, and attached to it and the circular partitions, are disposed twenty-eight hydraulic rams 8in. in diameter, for the purpose of pressing or pushing the shield forward. In the rear of the shield, or that portion of it which faces the completed tunnel, is a space which is merely enclosed within the outer skin of the shield; this space is called the tale of the shield. It always overlaps by 2ft. 6in., or one cast iron ring, the last completed portion of the tunnel, and within it is built up the various rings of iron with which the tunnel is lined.

know that it has bulk, for if we invert a tumbler in a basin of water, there will still be a space filled with air into which the water cannot enter. If we try the experiment, we shall find that this air space will be larger or smaller, depending on the depth to which we immerse the tumbler; consequently, we see that air is an elastic body. By properly constructed air compressing pumps we can force air down into a diving bell until all the water is expelled from it and the surplus escapes through the open bottom of the bell. If we then measure the amount of compression of the confined air we shall find it equivalent to the weight of a column of water equal to the area of the open bottom of the bell and as high as the depth of the water. It having been decided to use compressed air to keep out the water from the tunnel during its construction, the question arose what, having regard to the health of workers, was the greatest safe pressure to be adopted, as on this clearly depended the greatest depth to which the bottom of the tunnel and shafts could be carried. In going into the matter it was evident that it would not be a case of one or two men occasionally going down to perform some temporary work, but that gangs of from sixty to eighty men would have to be kept at work night and day for many months, consequently a safe maximum had to be arrived at. In places in America men had worked under a pressure of 48 lb. per square inch above the atmospheric pressure, that is 63 lb. absolute—at Stockwell, on the City and South London Railway, it was about 15 lb.,—and after many inquiries 35 lb. per square inch, or 50 lb. absolute, was determined upon. I have stated it in this way because in addition to whatever artificial pressure we may apply it must be borne in mind that we always have the initial pressure of the atmosphere to work under, which is about 15 lb. per square inch. In what follows, however, I shall speak only of the artificial pressure, leaving it to be understood that we always have the natural pressure in addition.

ST. PANCRAS ELECTRICITY WORKS—SECTION OF REFUSE DESTRUCTORS AND OF MAIN BUILDINGS

58ft. outside and 48ft. inside diameter, and is formed, as it were, of two skins of riveted wrought ironwork; the two skins are braced and held together by wrought iron struts and ties, the space between them being filled in solid with Portland cement concrete. Near the lower extremity of each shaft its side walls are perforated by two openings 29ft. 4in. in diameter. These openings are for the purpose of forming junctions with the tunnel, and were temporarily fitted during the time the shafts were being sunk by means of large wrought iron plugs. At a distance of 8ft. from the bottom the inner skin is bent outwards to join the outer skin, and together form a comparatively sharp cutting edge. All the shafts will be lined, when finished, with white glazed brickwork.

The shafts were sunk in the following manner:—Having been built up to a considerable height above the surface of the ground in the positions they were to occupy, the earth, clay, sand, &c., were excavated within the circumference of the shafts from below the cutting edge, and as this process of excavation proceeded the shaft sank into the ground, partly by its own weight, and in some cases assisted by additional weight placed upon it. When the final level was reached, the bottom for a depth of 13ft. was filled in with concrete, in which, and attached to the walls of the shaft, was fixed a water-tight wrought iron floor. As the junction between the tunnel and shafts nearest to the river had to be made under compressed air, provision was made for fixing temporary air-tight floors at a level of a few feet above the crown of the tunnel. These air-tight floors were held down by wrought iron girders 12ft. in length and 4ft. in depth, secured to the sides

Attached to the back or rearward part of the two circular stiffening partitions, and projecting into the tail of the shield, are two hydraulic erectors for placing the segments of the rings in position. There are two vertical rams which cause a rackwork to move up or down in a vertical direction. These racks gear into a pinion which carries an arm. Consequently, the vertical motion of the rack causes the arm to move through an arc of a little over 180 deg. This arm carries another ram by which the arm can be lengthened or shortened as desired. In working, the end of the arm can be attached to the lug or projection cast on the centre of the inner side of each segment, where, by the turning and lengthening motion of the arm, the segment can be placed in any desired part of the ring. This shield, weighing about 250 tons, was built in an excavation at the top of shaft No. 4, and when completed its ends were closed with timber to make it water-tight, and it was floated into shaft No. 4, which had been filled with water. The water was then pumped out of the shaft, and as the water fell, the shield, floating on its surface, gradually descended until it rested on the bottom. As above described, it will be noticed that the twelve working cells or pockets are open in front, and the shield is so used in hard or stiff ground, but in the gravel beds the working face has, except when the excavation is in progress, to be very carefully closed with the wrought iron shutters, secured with screws—as shown on the section—the mode of working which will be presently described.

Compressed air.—We all know that air at the sea level presses with a force of from 14¾ lb. to 15 lb. per square inch, and can support a column of mercury of from 30in. to 31in. in height. We

If the extreme safe pressure be fixed at 35 lb. per square inch, it follows that the bottom of the tunnel must not go much lower than 60ft. below high water mark. This being settled, the next point to be decided was how large could we make a circular tunnel so that it did not project upwards through the gravel into the river. In other words, what was the safe minimum amount of cover that could be allowed over the top of the tunnel and between it and the river bed. This, after much consideration, was provisionally fixed at 8ft.; but in construction, as will be seen on the section, the least depth was somewhat less. It was due to these considerations, coupled with the widths of the busy streets above spoken of and the size of the largest vehicles, such as furniture vans, &c., that the outside diameter was fixed at 27ft. Having now described the work and some of the main conditions under which it has to be constructed, you will have noticed that to keep out the water compressed air is employed, and that to drive the shield forward hydraulic pressure is used, the machinery for which requires a few words of description. For the purpose of air compression, six steam engines and air pumps are provided, and these are situate on the south bank of the river, near shafts Nos. 3 and 4. They have a united capacity of 1500-horse power, but only about 1000-horse power to 1200-horse power are used continuously, as one engine has to be kept idle in case of accident or breakdown. When working at 1000 to 1200-horse power these engines and pumps force into the tunnel about 8000 cubic feet of air per minute, or 17 tons weight per hour. The air from these various engines is first conducted into a wrought iron reservoir 28ft. in length and 7ft. in diameter, formed like a steam boiler. The first effect of compression, it is needless to say, is to raise the temperature of the air very much—in fact, to about 90deg. or 100deg. Fah.; consequently before it can be conducted into the tunnel it has to be cooled by passing it through a series of smaller tubes surrounded with cold water, like the surface condenser of a steam engine. From these coolers it is led in pipes down shaft No. 4 and along the tunnel, through the air-tight bulkhead, presently to be dealt with, to the working face.

In describing the shield I mentioned that it weighs about 250 tons, and that it has to be thrust forward as the excavation is completed, and each ring of plates, 2ft. 6in. in width, erected by the twenty-eight hydraulic rams, which abut or press upon the last completed ring of the tunnel. To produce the necessary total pressure of about 2800 to 3000 tons, a hydraulic pressure up to 2¾ tons per square inch has to be maintained. This is developed by two hydraulic engines of 70-horse power, is transmitted in hydraulic pipes down shaft No. 4, along the tunnel and through the air-tight bulkhead to the working face. I have previously spoken of a certain structure which I have called the air-tight bulkhead. This I must now describe. It is clear that if we are to use the compressed air in the tunnel to press against the working face and keep out the water, it must in some way be confined, or it would rush out backwards and escape up the shaft. To confine the air in the tunnel temporary air-tight walls or partitions called bulkheads are built across it. As these have to bear an outward thrust or bursting pressure of about 1000 tons, they are formed of massive walls 12ft. in thickness, built of brickwork in Portland cement. It is, however, obvious that they must not be solid, but must have means of access formed to allow of entrance and exit both for men and materials. To permit of this access air locks have to be formed through the bulkhead. These are for a similar purpose and act in a like manner to the locks on a canal, the difference being that in one case we have to overcome a difference of water level, and in the other a difference of pressure between that of the ordinary atmosphere outside—15 lb. per square inch—and the working pressure produced by the air compressing engines inside the bulkhead, be it 20 lb., 25 lb., or 30 lb. per square inch. The air locks consist of wrought iron cylinders 15ft. in length and 6ft. in diameter, securely built into the brickwork of the bulkhead. There are two of these air locks at the level of the road near the bottom, each provided with two doors 5ft. by 4ft., fixed at either end of the lock, and opening inwards towards the pressure inside. There is another but smaller air lock placed near the top of the tunnel to permit of escape in case of accident. Supposing you wish to enter, the outer door is open, but the inner one closed and pressed against by a force of, say, 30 tons. It is clear that you cannot open this door until you have equalised the pressure on both sides of it. To do this you enter the lock and close the outer door to prevent the escape of air, after which a tap or cock is opened, which permits the compressed air from inside to rush into the lock until the pressure within it is equal to that on the inner side of the bulkhead. As soon as this equality is established, the inner door can be opened, and you step into the working pressure.

Visit to the tunnel.—In attempting to describe the work of construction, I do not think I can do better than in imagination to conduct you over the work during a visit of inspection. It is first necessary for ladies and gentlemen alike to put on waterproof boots, woollen overalls and caps, so as to keep dry and clean; these are in readiness for the purpose at the tunnel. Descending by the steps at the end of the open approach on the south side of the river, we pass for over 300 yards through the finished cut-and-cover portion of the work, and have an opportunity of noticing what will be the general size and appearance of the interior of the tunnel, and that, although it is all below high water mark, and its lower end beneath the level of the bed of the river, yet it is quite dry and dusty under foot. On reaching the bottom of shaft No. 4, the large steam pumps for lifting out the water during construction will be noticed, for it must be remembered that although the work when finished will be quite dry and water-tight, yet during construction, even with the use of compressed air, a large volume of water enters the work and has to be got rid of. This mainly arises from the fact that the difference in hydrostatic external pressure due to the 27ft. in height of the shield amounts to about 9 lb. per square inch; so that if the full air pressure due to the external hydrostatic pressure at the bottom of the shield and working face were always kept up, much of it would escape in too large volumes from the top of the excavation and through any porous soil. In fact, to prevent this too rapid escape of air through the gravel, as well as to weight the material over the shield, where the covering was least in thickness above it, clay, as shown on the section, was deposited in the bed of the river for a width of 150ft. and from 10ft. to 15ft. in depth, immediately over the part of the tunnel under construction. While the tunnel was being formed beneath the river, there was always a very large escape of air which boiled up through the water, and also came up in some places inland at a distance of 800ft. from the working face. Notwithstanding all the precautions taken, the air pressure on two occasions blew up the bottom of the river, and once the surface water rose to a height of 25ft. over a diameter of 50ft. Any water, therefore, which enters the tunnel between the working face and the air-tight bulkhead is forced out through pipes which extend from the working face through the air-tight bulkhead to the bottom of shaft No. 4, the superior air pressure within the working part of the tunnel being used for the purpose, and from the bottom of shaft No. 4 it is raised by steam pumps to the surface.

Passing from the bottom of shaft No. 4 down the incline to shaft No. 3, the visitor may observe the cast iron rings of which the tunnel is built up quite uncovered, as the inner lining of concrete has not yet been inserted. It will be noticed that the work is lighted by means of incandescent electric lamps, which give sufficient light to see that as fixed the plates are quite water-tight, and but for appearance sake require no internal lining. After passing the bottom of shaft No. 3, which is domed over, we enter on the portion of the tunnel below the river, and most probably soon after hear a loud rumbling roaring noise. This is caused by the escape of the compressed air from one of the air locks as some men or materials are being locked out. Arriving at the air-tight bulkhead, we enter the lock, close the outer door, and turn on the compressed air, which enters from the working space beyond the bulkhead. The effect of so doing is at once apparent, for the noise of the inrushing air is as loud as that of the steam escaping from some large steam boiler, and quite drowns the voice and renders hearing impossible. At the same time every one feels a more or less acute pain in the ears, caused by the increased pressure of the air on the outer surface of the drum of the ear; this can in most cases be removed by equalising the pressure through the Eustachian tubes, which communicate with the middle ear; this is effected by swallowing and blowing into the nose when it is pinched with the fingers, but if the pain becomes and continues very acute, the person suffering should at once leave the air lock. As the air in the lock becomes more compressed, the temperature rises rapidly; this is due to the compression, and only lasts while in the lock, for as soon as equalisation is established, and the inner door is opened, and you step into the working space, you find the temperature falls to about 60 deg. to 65 deg. Fah.

I am often asked what it feels like in compressed air. This, I think, must in all cases be a personal matter. But summing up the result of my many weekly visits to the tunnel during the past two years, I should say that I feel no difference from that when under the ordinary atmospheric pressure. There is a very slight feeling of exhilaration if the pressure is over 20 lb. per square inch, probably caused by the larger amount of oxygen absorbed by the lungs; everyone appears to speak with a nasal intonation; you cannot whistle, and the skin acts more freely than at the same temperature under normal conditions. I should here note that no one becomes ill from the effects of compressed air while under its pressure; the baneful effects, if experienced at all, usually show themselves on coming out of it. But I have arrived at the conclusion that, among otherwise healthy persons, some can and some cannot withstand air pressure, and I have had the pleasure of conducting many persons over the works, from little girls of thirteen up to gentlemen of over seventy years of age, who have not felt the least ill effects from compressed air. Passing on to the shield and the working face, we see the two main operations in progress—(1) excavating, and (2) erecting the cast iron rings of the tunnel.

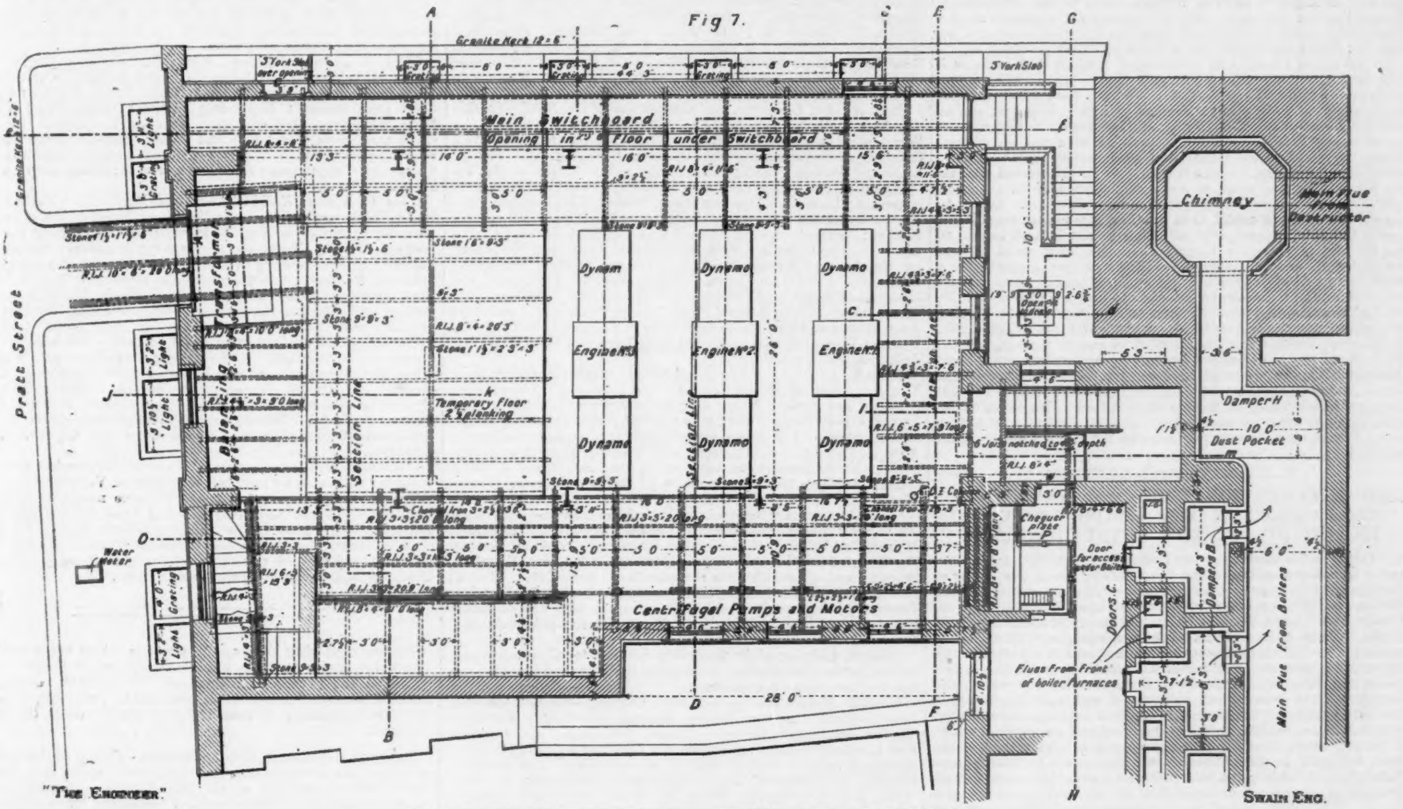
Excavation.—As to the excavation, the mode of conducting it will depend on the kind of ground being pushed through. If it be hard or stiff enough to stand with a vertical face when pressed against by the various partitions of the shield, the men simply dig or pick it away in front for a few inches or a foot or two, passing the excavated material out to the stage behind the shield, from which it is tipped into wagons and removed. After a sufficient amount has been cleared and loosened in front of the shield, the latter is by the hydraulic jacks pressed forward, it may be a few inches or perhaps 2ft. 6in., the distance depending on the nature of the ground. Each ring displaces 54 cubic yards, and progress has varied from 1ft. up to 10ft. a day. If, however, the material be gravel, the progress is very slow, as this material will not remain vertical when dug into, but runs down as fast as it is excavated. Besides which, so rapid is the escape of air that, if precautions were not taken, it would pass out in dangerous quantities. To obviate this, and to support the face, the front of each pocket or working face is closed with three wrought iron shutters, pressed forward by powerful screws, and all the joints luted with clay. In these circumstances the excavation is made either by raking out the gravel through holes in the shutters, or by drawing them back one at a time, digging out a small portion, and then screwing up the shutter again. When all the shutters have been screwed forward the shield is pressed, and as the screws are so arranged as to allow of their slipping through the nuts attached to the shield, the result is that it moves forward past the shutters which remain in the positions into which they have been screwed. It need not be said that this is slow and tedious work, requiring great skill and patience.

Erecting the rings.—After the shield has been pressed forward so as to leave a clear space in the tail of 2ft. 6in., the erectors are brought into work, and, as before described, the various segments and the key piece erected. It will be noticed that as the tail of the shield overlaps the last finished ring of plates it leaves an annular vacuity, 4in. in width, between the back of the plates and the natural ground. This space is made solid by the injection of grout under pneumatic pressure by means of the contrivance patented by Mr. Greathead. This consists of a closed horizontal cylinder, in which lime or cement can be mixed to the consistency of thick cream by a horizontal spindle with arms which pass through it. The upper side is furnished with a pipe, through which air pressure can be applied to the surface of the grout, and from the lower side the grout is conveyed in another pipe to the holes in the plates, through which it is forced by the air pressure. To provide against accidents, two precautions are adopted in case of an inrush of water. One is an elevated temporary wooden gangway or path extending from the shield to the upper escape air lock in the air-tight bulkhead. The other is a fixed curtain of wrought iron, which descends to the semi-diameter of the tunnel, so that in case of an irruption of water it would not fill the entire tunnel, but a certain portion of compressed air would be trapped between the curtain and the air lock, and so form a kind of elongated diving bell. Having now viewed all that is to be seen in compressed air, we return to the air lock for the purpose of passing out. This is in some respects different from passing in, and is an operation requiring some little time and caution, as the removal of the artificial air pressure and the return to normal conditions is more than equivalent to an ascent beyond the tops of the highest mountains on the earth, as the artificial pressure may be 30 lb. per square inch, all of which has to be removed before we return to the normal 15 lb. As to sensation, no difficulties about the treatment of the ears is experienced, as the compressed air in the middle ear gradually and naturally discharges itself with a not unpleasant crackling sound. Owing, however, to the expansion of the air in the lock, the temperature falls rapidly, so much so that the invisible aqueous vapour contained in the air is deposited, as a thick damp fog and a chill is experienced. Beyond this there is nothing particular to notice.

From the tunnel we ascend the shaft No. 4, and in the cabin at the top take a cup of hot coffee, which slight stimulant is sufficient to restore the system to its usual condition. I am frequently asked if we have found any objects of interest or antiquity in our various excavations; but as most of our work has been through the tertiary beds of the London clay and Woolwich series, nothing but the fossils peculiar to these formations have been met with. On the table will be found specimens of the base bed of the London clay, and of the conglomerate bed which lies just below it. These two formations have also been met with on other works, as at Abbey Mills and the Beckton Gas Works. There is also a specimen of the shelly clay of the Woolwich series. In the superficial gravel, part of an elephant's tusk was found on the south shore of the river; a similar tusk was also found on another work in the gravel beds near Abbey Mills, at Stratford. On the north side of the river at Blackwall Cross, about 8ft. below the street level, a human skeleton was found, and as a stake was also found which appeared to have been driven through the body at the time of burial, in all probability the remains were those of some poor suicide, who had been interred with all the superstitious rites of our ancestors. Beyond the above I do not think anything of interest has been discovered.

Experience of compressed air.—In some previous works carried out under compressed air much illness and some deaths had occurred. The illness of the more frequent, though not serious, consequence is violent and acute pains of a neuralgic kind generally in the limbs, and which is experienced at the time of, or shortly after, coming out of compressed air. The more serious, and in some instances fatal, cases took the form of vertigo and paralysis, usually of the legs. Consequently, at an early period, the London County Council adopted every precaution; they obtained Parliamentary power to compensate persons permanently or temporarily injured, and they appointed a resident medical officer, Dr. Snell, whose duty it was not only to attend to cases of illness, but to see that none but healthy men were allowed on the work, and to keep

Fig 7.



"THE ENGINEER" SWAIN ENG.

ST. PANCRAS ELECTRICITY WORKS—GENERAL PLAN OF BUILDINGS a watch on all the men employed in compressed air, besides which he was instructed to note from a medical point of view and make a study of all the conditions of the problem. We have now been at work under compressed air for about two years; we have had no deaths, and only one case of permanent injury—a case of Menier's disease, due to rupture of the semi-circular canal of the inner ear. It had often been noticed on previous works that illness was most prevalent when the work progressed most slowly, and that it decreased as the progress became more rapid. We now believe from our experience at Blackwall that this was due to the larger amount of air pumped down during rapid work. Without for a moment wishing in any way to forestall Dr. Snell, who will no doubt make public the result of his observations at the proper time, we believe that up to a pressure of from 30 lb. to 35 lb. per square inch healthy men can work with almost an entire absence of illness, if a sufficient amount of compressed air, say 8000 to 9000 cubic feet per hour, be supplied to each man.

Conclusion.—In drawing this discourse to a conclusion, I feel that I have but very imperfectly performed the duty which I have undertaken. We have now completed all the work on the south side, the river has been passed, and we are working up the incline near shaft No. 1, and if all goes well we hope to complete the whole by about March next year. In contemplating the work at Blackwall, it is interesting to compare the progress in engineering work during the past fifty years. Brunel's tunnel was of about the same length as the portion under the river at Blackwall, and it took about nine years, with many long pauses, to complete; the portion of the Blackwall Tunnel under the river between shafts 2 and 3 was tunnelled in about thirteen months. The cost of Brunel's tunnel was at the rate of about £1300 per yard, while that at Blackwall averages £550 per yard. This is most gratifying after the gloomy forebodings by which we were met before we commenced the work—it was at that time predicted, and I was personally warned by members of my own profession, that if we succeeded at all, it would only be by chance, and at the cost of much suffering and death. The success that has attended us is due to all who have been engaged upon the work, and particularly to the skill and untiring energy of three gentlemen, the two resident engineers, Messrs. Hay and Fitzmaurice, and to Mr. Moir, who acts as engineer for, and representative of, the contractors, Messrs. Pearson and Son. But in claiming for ourselves at the present time credit for the success that has attended our efforts, we must not forget the honour due to those who have preceded us.

No one can in a large and complicated modern work such as I have been describing claim for himself the exclusive credit for the whole or any important part of it. We have been using a shield under compressed air, pushed forward by hydraulic power, and at once the names of Bramah, Brunel, and Dundonald remind us that we are largely indebted to them. Much has been said and written about the shield we have used, and some names have been associated with its design. I wish it clearly to be understood that no one has any right to do so, as it is a combination of all the good points in many previous efforts in the same direction. But if to anyone is due more credit than another, it is to that remarkable genius the elder Brunel, who, although he was himself unable to use his own invention, saw clearly how the work could be best accomplished, and as far back as 1818 took out a patent for a shield and mode of constructing subaqueous tunnels. As described in and shown on the drawings attached to his specification of 1818, we find a cylindrical wrought iron shield, divided into working cells or pockets, the tail of which overlapped a tunnel some 20ft. in diameter, which tunnel was formed of cast iron rings, and the whole shield was to be pressed forward by hydraulic jacks. From Dundonald's specification of 1830, we get the mode of making a tunnel under compressed air, and to Bramah is due in a great measure the invention of the hydraulic press. Therefore, in this as in so many other of our works, it is seen that we owe a deep debt of gratitude to our predecessors for the success we have attained.

THE INTERNATIONAL HORSE AND HORSELESS CARRIAGE AND ROADS LOCOMOTION EXHIBITION AT THE CRYSTAL PALACE.

ON Friday last a meeting of the Honorary Committee of Advice—under the chairmanship of the Lord Mayor, who is the Master of the Ancient Company of Coachmakers—took place at the Mansion House. After some observations by the Lord Mayor on the connection between the Mansion House and the great exhibitions held at the Crystal Palace, Sir David Salomons proposed the following resolution:—"That, having regard to the great and daily increasing interest taken in the revival of self-propelling traffic on common roads, and the great magnitude of the industries involved in the manufacture of horse-drawn vehicles, as well as to the fact that the introduction of mechanically-propelled carriages is calculated to revolutionise modern modes of transport and travel, the present is an opportune time for organising upon a large scale—on the lines indicated in the announcement just read—an international Exhibition of both horse and horseless carriages, together with everything pertaining to locomotion of all kinds upon common roads. That on account of its size, the extent of its grounds, and its position in regard to the metropolis, the Crystal Palace is the most suitable *locale*. That the holding of such an Exhibition in London, and at this period, would be highly advantageous to the industries involved, including as they do not only the manufacture of light road carriages suitable for private users, professional men, and the trading classes generally, but also of mechanically-propelled vehicles suitable for the economical transport of agricultural produce. That, being calculated to stimulate the engineers of this country to greater efforts in improving and perfecting the motors and mechanical arrangements of self-propelling vehicles, the Exhibition is eminently worthy of influential support." In proposing this resolution he drew attention to the importance and interest attaching to the proposed exhibition, especially with respect to the horseless carriage industry, which will, no doubt, rapidly reach great proportions. Some remarks were made on the necessity for an early repeal of the existing restrictions at present preventing the use of horseless carriages, and on the difference between the position of the users and builders of these vehicles on the Continent and in this country. The industry in horseless carriage and trading vehicles had already become an important industry in France, while in England, where nearly sixty years ago a considerable degree of perfection in steam carriages had been reached, there was no such industry. This resolution was seconded by Mr. George J. Jacobs, president of the Institute of British Carriage Manufacturers, and it was unanimously agreed to.

Mr. Samuel Green then moved the appointment of the honorary Executive Committee for horse-drawn vehicles.

Mr. Vaughan Pendred seconded this motion, and dwelt on the importance of some of the points raised by Sir David Salomons. He also spoke of the offer by the proprietors of THE ENGINEER of prizes to the value of one thousand guineas with a view to stimulating the design of and industry in mechanical road carriages in this country.

On the motion of Major Flood Page, seconded by Captain Simonds, chief of the Metropolitan Fire Brigade, the honorary Executive Committee for mechanically-propelled vehicles was appointed.

The Executive Committee includes the following:—Horse-drawn vehicles: Mr. Robert Alford, Mr. Charles Thomas Bartlett, Mr. Andrew W. Barr, Mr. Frederic Chancellor, Mr. George N. Hooper, Mr. George J. Jacobs, Mr. Peter De Lande Long, Sir John B. Monckton, Colonel James Peters, Mr. Percy Preston, Mr. John Philipson. Mechanically-propelled vehicles: Sir Frederick Bramwell, Bart., F.R.S., Sir David Lionel Salomons, Bart., Sir Douglas Galton, F.R.S., Sir Henry Trueman Wood, Mr. Andrew W. Barr, Mr. W. Worby Beaumont, Professor Vernon C. Boys, Mr. James Dredge, Mr. Walter Hancock, Dr. John Hopkinson, F.R.S., Professor D. E. Hughes, F.R.S., Mr. Edmund Macrory, Q.C., Mr. A. R. Sennett. Mr. A. R. Sennett, Assoc. M. Inst. C.E., was appointed honorary executive commissioner; Mr. Henry Gillman, the manager of the Crystal Palace, having the general management of the whole exhibition.

The prospectus of the International Exhibition now being organised by the Crystal Palace Authorities, aided by the large committee of advice and executive committees representing the many numerous interests which such an exhibition will comprise, has been issued. The exhibition will be held under very influential patronage, and will be opened in May.

The prospectus mentions that there exists at the moment in this country an industry—that of the manufacture of self-propelling vehicles for use upon common roads—which is scarcely yet beyond its nascent condition, but which is far more advanced, and indeed has assumed considerable magnitude, in other countries, and in regard to which proper publicity and demonstration cannot be given in this country under existing legislation, except in extensive private grounds such as those attached to the Crystal Palace. It is intended that concurrently with the exhibition and demonstration of the most modern applications of science to mechanical locomotion upon common roads, there will be an exhibition of all kinds of animal-drawn road vehicles and carriages of both historical and current interest, including illustrations of ancient modes of travel, and of road conveyances now displaced by the introduction of railways. The Crystal Palace Authorities will also be aided by the practical assistance of the City Companies, the Worshipful Company of Coachmakers, the Institute of British Carriage Manufacturers, as well as private owners, who are lending their valuable and unique collections.

The exhibition is divided in to twelve sections, which are again subdivided into Classes:—Section I. (Classes A, B, and D), Fine Art, Literature, Sculpture, Antiques and Curios, and Illustrations of Primitive Modes of Travel. Section II. (Classes B and E), Ancient and Modern Harness. Section III. (Classes C and D), Ancient and Mediæval Carriages. Section IV. (Class D), Ancient and Modern Carriage of the Mails. Section V. (Classes E, K, L, P, and Z), Accessories to Modern Travel and Sport. Section VI. (Classes G and H), Coaching. Section VII. (Classes F, G, and H), Modern Carriages. Section VIII. (Classes H, J, and Z), Modern Transport. Section IX. (Class Y), Military and Cycle Transport. Section X. (Classes M, N, O W, and X), Material, Plant, and Machinery. Section XI. (Classes Q, U, V, and Y), Mechanical Road Locomotion. Section XII. (Classes R, S, and T), Horseless Carriages.

The following is the classification of exhibits:—

Class A. Art, Literature, and Journalism of the Road.—In this class are included the valuable collection kindly lent by the Worshipful Company of Coachmakers and the Institute of British Carriage Manufacturers. Oil Paintings; Engravings; Prints; Etchings; Models; Casts; Bronzes and other Works of Art relating to Horsemanship, Coaching, Vehicles, Travel, and Transport generally; Books and Treatises upon Roads; Road Construction; Horses and Mules; Harness, Ancient and Modern; Saddlery and Bitting; Driving; Cycling; Coach and Carriage Design; Coaching; Coach and Carriage Building; Special Plant and Machinery for Coach and Carriage Building; Civil and Military Transport; Mechanical Road Locomotion; Steam, Electric, Petroleum, and other Road Motors and Carriages; Man-propelled Vehicles; Cycle Construction; Cycle Makers' Special Tools, Plant, and Machinery; Journals devoted entirely to the Road, to Coaching, to Civil and Military Transport, and to Mechanically Propelled Road Vehicles; Ordnance and Road Maps.

Class B. Antiques and Curios.—Ancient, Mediæval, and Antique Trappings and Caparisonments; Antique Lorrinary; Ancient Bits, Stirrups, and Spurs; Whips used by celebrated Coachmen; Celebrated Coach Horns; Old times Coaching and Travelling accessories; Mediæval Harness and Trappings; Antique Saddlery; Antique Carriage Laces; Regal and Queenly Travelling Equipments; Heirlooms and Souvenirs of the Road and Travel in olden times; Antique Carriage Heraldry; Antique Harness, Chased Work, and Heraldry.

Class C. Ancient Conveyances and Modes of Travel.—(*a*) Wheelless: Snow Shoes; Snow Skates; Skees; Sledges; Toboggans; Man-carried Litters; Horse-carried Litters; Palanquins; Sedans. (*b*) Wheeled: Wheeled Sedans; Ancient Chariots; Egyptian, Roman, and other Chariots; Carouches; Cabriolets; Chares; Berlines; Post Chaises; Chariots (four-wheeled); Curricles; Tilburies; Buggies; Coaches; Whiskeys; Carrioles; Buckboards; Barouches; Vis-à-vis; Dandies; Dandy Horses; Velocipedes; Bone-shakers.

Class D. Carriage of the Mails.—Is devoted to all things appertaining to the Carrying and Delivery of the Mails and Parcels Post, and to Travelling with the Mails.

Class E. Modern Harness and Horse Clothing.—Modern Harness, Four-in-Hand, Tandem, Single, Racing, and Heavy Haulage; Quickly Detachable Harness, Collars, Pole-chains, and Gear for Fire Engines; Saddles; Safety Saddle Bars and Releasing devices; Stirrups; Spurs; Collars, stuffed, spring-packed, and metallic; Farriery and Farriers' Tools; Horseshoes, hand-made, machine-made, and anti-slipping; Horseshoe Nails; Removable Roughs; Whips; Whip Sockets; Rein-holders; Breaking-in and Training Appliances; Mechanical Jockeys; Veterinary Appliances; Medicines; Foods; Horse Clothing; Monogram Loin Covers; Pack-horse Trappings suitable for the Colonies.

Class F. Modern Animal-drawn Vehicles (Two-wheeled Pleasure Conveyances).—This class includes Gigs; Dogcarts; Village Carts; Pony Carts; Buggies; Stanhopes; Irish Outside and Inside Cars; Mail Carts; American Trotting Buggies; Private Cabs.

Class G. Modern Animal-drawn Vehicles (Four-wheeled Pleasure Conveyances). This class includes Mail Coaches; Four-in-Hand Pleasure Coaches; Private Omnibuses; Sociables; Broughams; Landaus; Landaulettes; Victorias; Spider Phaetons; Ladies' Phaetons; Mail Phaetons; Wagonettes; Tea Carts; Pony Chaises; Dogcarts (four-wheeled).

Class H. Modern Animal-drawn Vehicles (Public and Trade Conveyances.)—(*a*) Four-wheeled: Omnibuses; Drags; Char-à-Bancs; Cabs (public); Trade Vans, &c. (*b*) Two-wheeled: Cabs (public); Tradesmen's Delivery Carts, &c.

Class J. Modern Animal-drawn Vehicles (Heavy Haulage and Special Transport Conveyances.) — Town Wagons; Tumbrils; Trollies; Lurries; Drays and Vehicles for general Merchandise; Special Vehicles for Timber, Metallic Girder, Water Main, Stone, Plate Glass, and Liquid Haulage; Wheeled Fire Escapes and Fire Engines; Agricultural Carts and Wagons; Wagons specially adapted for use in Mechanical Haulage.

Class K. Coach, Carriage, and Hunting Accessories.—Coach and Carriage Lamps, internal and external; Mats; Rugs; Umbrellas; Foot Cosies and Warmers; Electric and other Heaters; Travelling Outfits and Containers; Splash-board Clocks; Carriage Clocks; Coachmen's Communicators and Indicators; Velocimeters: Cyclometers; Coach Horns; Warning Bells and Syrens.

Class L. Coaching, Driving, and Equestrian Tailoring.—Coach-Guard Uniforms; Coachmen and Footmen's Liveries; Livery Hats; Cockades; Monogram and Coat of Arms Buttons; M.F.H. Huntsmen's and Whips' Caps; Buckskins; Cords and "Pinks;" Jockeys' Outfits; Special Driving and Covert Coats; Top-boots; Ladies' Habits —Cycling Costumes for both Ladies and Gentlemen; Hunting and Driving Waterproofs; Travelling Clothing for all climates.

Class M. Coach and Carriage Builders' Material.—Coach and Carriage Leathers; Coach Laces; Lining Cloths; Brocades; Genoas; Tabarets; Velvet Piles and other Lining Materials; Budget Trimming; Curtains; Tassels; Trimming Material and Gimping; Spring and Roller Blinds; Buttons; Communicator Cords; Speaking Tubes; Colours; Oils; Varnishes; Painting Material; Lining Tools; Candles; Lamp Oils.

Class N. Coach and Carriage Builders' Parts.—Hand-made and Machine-made Wheels; Heavy Haulage Wheels; Channel Felloe Wheels; India-rubber Tire Wheels; Pneumatic Tire Wheels; Metallic Boxes; Roller and Ball Bearings; Axles; Springs, Elliptic, Metallic C, and Strap Suspension; Body Parts; Shafts; Forgings; Bolts; Nuts; Washers; Pins; Door and Window Furniture and Fittings; Self-Acting Door Opening and Closing Gear; Material and New Inventions connected with Springs, Axles, Boxes, Wheels, Tires (metallic and anti-percussive), Poles, Shafts, Fore-Carriages, and Carriage Constructional parts generally.

Class O. Coach and Carriage Builders' Plant and Machinery.—Machine and Hand Tools used in coach and carriage building; Special Wood-working Machinery used in body-making; Wheel-making Machinery; Spoke and Copying Lathes; Tire Rolling, Drawing, Spinning, Fitting, Removing, and Shrinking Machinery; Shaft-making and Bending Plant; Window Glass Bevelling and Embossing; Pneumatic Spray Painting Plant.

Class P. Stable and Harness-room Fitments and Equipment.—Metallic Stalls; Loose Boxes; Mangers and Fittings; Racks; Special Pavings; Cornbins, rat proof and metallic; Harness Brackets; Jacks and Lifting Gear; Mechanical and Electric Horse Groomers and Clippers; Carriage and Stable Utensils of every description.

Class Q. Modern Muscularly Propelled Vehicles.—Cycle Chaises; Cycle Cabs; Special Gear Cycles; Cycle Fire Engines; Cycle Tradesmen's Carts; Cycle Parcels Deliveries.

Class R. Horseless Carriages. — Mechanically Self-propelling Passenger Carriages (public or private) of all kinds driven by Electricity.

Class S. Horseless Carriages. — Mechanically Self-propelling Passenger Carriages (public or private) of all kinds driven by Springs, Caustic Soda, Ammonia, Gas, CO_2, and either Spirit or Petroleum, ignited within the cylinders.

Class T. Horseless Carriages.—Mechanically Self-propelling Passenger Carriages (public or private) of all kinds driven by Steam, Compressed Air, Compressed Gas, Hot Air, Petroleum used as an evaporative fuel for boiling either water or spirit, and all Motors actuated by the expansion of gases but in which no ignition takes place within the cylinder.

Class U. Mechanically-Propelled Road Vehicles.—Mechanically Self-propelling Goods-carrying, Composite, or Haulage Vehicles driven by Electricity, Petroleum, or Steam, or other motive power.

Class V. Motors and Gears.—Steam, Electric, Compressed Air, Spirit, and all kinds of Motors suitable for Mechanically Self-propelling Road Vehicles, together with the various and special Gears for use in conjunction with them.

Class W. Autocar Builders' Materials and Parts.—Light Steel Construction Tube; Aluminium Castings; Metallic Wheel Rims; Wire Spoke or Suspension Wheels; Light Spoke Wheels; Heavy Road Loco Wheels; Expanding Wheels; Boxes Sheet Metal; Deep Stampings, hot and cold Pressings; Sprocket Wheels; Chain and Tooth Gear; Ball and Roller Bearings; Balls; India-rubber and Pneumatic Tires; Armoured Tires; Pneumatic Tire Valves and Compressors; Special means of mounting and removing Pneumatic Tires.

Class X. Autocar Builders' Plant and Machinery.—Machine and Hand Tools used in Autocar Building; Metallic Wheel-making Machinery; Metal-working Machinery; Lathes, Shaping, Drilling, Milling, Slotting Machines; Contouring Machines; Rubber and Pneumatic Tire-making Plant; Tire, Rolling, Drawing and Spinning Machinery; New Inventions relating to Auto-Carriage Construction; Electro-Silver and Nickel-Plating Plant; Grinding, Buffing, and Polishing Machinery; Electric Welding, Bending, and Setting Plant.

Class Y. Military Locomotion and Transport.—Military Traction Engines; Gun Carriages; Army Service Corps Transport Wagons; Hospital Corps Ambulances (wheeled) Panier Ambulances, Army Medical Department Transport of Material; Mule Transport; Devices for attaching Guns and Carriages to Mule Saddles; Cycle Corps Equipment; Mechanically Propelled Gun Carriages and Transport Wagons; Cycle Machine Guns and Light Ordnance Carriages.

Class Z. Miscellaneous.—Special Vehicles for the live and dead transport of Horses by road and rail; Special Vehicles for the rail transport of Cycles; Ambulances; Humane means of despatch; Life-boat Transport Carriages; Board of Trade Rocket Apparatus Transport Carriages; Stable Slinging Gear; Marine Transport Slinging Gear; Stag and Hound Carts and Vans; Home Exercisers for both Saddle and Cycle; Coaching and Hunting Trophies; Challenge and Competition Cups and Shields.

PORTSMOUTH NEW DOCKS.—In our account of these works in THE ENGINEER of the 21st ult. we mentioned the names of the makers of the Portland cement used. We omitted, however, the names of Messrs. Charles Francis, Son, and Co., who inform us that they were contractors of from 17,000 to 22,000 tons of the cement required.

TRADE AND BUSINESS ANNOUNCEMENTS.—Owing to the falling in of a lease, the old-established business carried on for fifty years by Samuel Fisher and Co., at the Nile Foundry, Birmingham, as specialists in tube-making plant and machinery for sugar making, has been transferred to Pershore under an amalgamation with the well-known firm of E. Humphries and Co., Limited, agricultural and general engineers of that place, where in future the combined businesses will be carried on under the management of the acting partners in the late Birmingham firm.

ELECTRIC MOTOR CARS are to be tried on the Manhattan Elevated Railway in New York city. The system to be experimented with is that controlled by the Electric Storage Battery Company, of Philadelphia, in which the motor car has a storage battery sufficiently powerful to operate it for a round trip. The battery furnishes part of the current required by the motors when starting a train or climbing a steep grade, and all the current when the motor car is on the curve or on side tracks at terminals. On the other hand, when the train is running on a straight and level track the current distributing rail furnishes current in excess of that required by the motors, which goes to charge the batteries. *Engineering News* says a special advantage of this system of elevated railway service is that breaks in the line by fire or accident do not stop the operation of the whole road, as the trains can be run by battery alone over such portions of the line as are dead.

THE INSTITUTION OF JUNIOR ENGINEERS.—On Saturday, 29th ult., the members of this Institution visited, by invitation of the directors, the National Skating Palace, to inspect its engineering features, the party numbering over 150. They were shown over by Mr. A. H. Tyler, Mr. Cooper, and other gentlemen. At the conclusion of the visit, Mr. H. B. Vorley, vice-chairman of the Institution, expressed the members' acknowledgments for the special arrangements which had been made for their benefit on the occasion. The two main refrigerating engines of this installation were supplied by Messrs. J. and E. Hall, and are each capable of making 25 tons of ice per 24 hours. The electric light engines, by Messrs. Crompton and Co., are of the inverted vertical compound type, and indicate 57-horse power at 250 revolutions per minute. Three Davey-Paxman 40 nominal horse-power boilers of the locomotive type supply steam. The water is obtained from a well 353ft. deep, which was sunk by Messrs. Tilley and Sons. The steam from the main engines is condensed in jet condensers worked by the engines themselves, and that from the electric light engines by an evaporative condenser situated on the roof, the air pump being worked by an independent engine. The refrigerating engines, which are of the compound tandem variable expansion type, are worked upon Messrs. Hall's carbonic acid system—cooling a solution of chloride of calcium by the evaporation of the liquefied gas. The brine is circulated by centrifugal pumps through the entire rink floor, consisting of a series of shallow tanks, upon the upper surface of which the ice is formed. The actual skating area of the rink is 11,117 square feet.

RAILWAY MATTERS.

It is notified that the Snowdonian Railway is finished, and will certainly be ready for, very possibly, a huge summer traffic.

Although it is only seventy years since the first railway in the world was finished, four hundred thousand miles have been constructed, the British Empire accounting for about one-sixth of this.

The Madras Electric Tramway Company is making great extensions, in very striking contrast to the progression by inches, with much retracing of footsteps, that formerly made the company's early days so unfortunate.

The Indian Government has made arrangements for taking land in the Hassan district for the construction of a railway from Arsikere to Mangalore, *viâ* Habankatta, Adiballi, Bogdedudda, Hassan, Alur, Belagod, Saklespur, Hebsala, Yettiyanhalli Valley, Kempkal and Marlibid.

During the year 1895 the Baldwin Locomotive Works built 401 locomotives. The output is about 28 per cent. in excess of that of the previous year, when but 313 locomotives were built, and about 52 per cent. of the product of 1893, when 763 locomotives were sent out. Of the 401 locomotives built during the past year, 162 were for export. There are now in hand orders for 90 engines. Of the number 20 constitute the balance of the order placed some months ago by the Russian Government. These 20 engines are now about ready for shipment.

The formal ceremony of cutting the first sod of the Ahmedabad-Parantij Railway Company was performed recently by the Governor of Bombay, and in the meantime the work has been taken in hand by the disposal of the Bombay-Baroda and Central India Railway Company, who are to construct and work the line for the proprietary company. An extension of the line as far as Ahmednagar, in the Idar State, has already been sanctioned, making the total length of the line about fifty-four miles. A further extension to Oodeypore will doubtless follow at no distant rate.

The Canadian House of Commons on Tuesday night, by 55 votes to 54, threw out the Bill enabling the Chignecto-Maine Railway Company to issue further bonds and extending the time for the completion of the enterprise. Nearly £700,000 of British capital has already been sunk in the project. The members who spoke against the Bill said that they were rendering good service to investors, as the additional capital required—£300,000—would be simply thrown away, and the project would never pay. The *Times* says, "Mr. Provand, M.P. for the Blackfriars Division of Glasgow, has been in Ottawa some weeks in the interests of the railway."

A large electric locomotive, built for experimental purposes by the Baldwin-Westinghouse combination, has been shipped from the Baldwin Locomotive Works at Philadelphia to the Westinghouse Electric and Manufacturing Company, at East Pittsburgh, where the electric equipment will be put in. This locomotive is intended for passenger service and has two four wheel locomotive trucks, each with a 6ft. wheel base and 42in. wheels. It is designed for 1000-horse power, and the weight on drivers is 120,000 lb. A short line has been built near the Westinghouse Electric and Manufacturing Company's works, on which this locomotive will be tried.

The Metropolitan Traction Company of New York city reports very favourably on the substitution of mechanical traction for horses in the operation of its system of street railroads. Under the horse system operating expenses were 70 per cent. of the gross receipts, while after substitution of mechanical traction—cable and underground electricity—on 20 of the 120 miles under the company's control, they amounted to but 54·4 per cent. On the Broadway line alone, the *Engineering Record* says, operating expenses have been reduced from 66 to 38 per cent. Recent additions to the system make its mileage of single-track cable, 25·34; electric conduit, 6·78; and horses, 131·38.

The returns of accidents on Indian Railways for the quarter ending March 31st, 1895, are now published. The total number killed was eight, and fourteen were injured, against nine and twenty-six for the corresponding period of the four previous quarters. The largest number of accidents occurred on the specal gauge lines. The East Indian and North-Western Railways were responsible for five and eleven collisions respectively more than in the four previous quarters. The Southern Mahratta Railway had the largest number of cattle accidents, *i.e.*, trains running over cattle straying on the line. In proportion to train mileage run, the number of accidents was largest on the Jorehat State Railway, and smallest on the Great Indian Peninsular Railway. Among the accidents recorded, the most serious was that which occurred on March 2nd, 1895, when the down Jubbulpore mail was derailed, owing to a rail having been maliciously removed between Jubbulpore and Deoree, which resulted in the death of four railway servants, and severe injuries to three passengers and one railway servant. The *Indian Engineer* says the marvel is that the casualties were not heavier.

For some time past the question of taking some step with the view of arresting the continued decrease in the second-class traffic, which for some years has been a prominent feature in railway accounts, has been engaging the careful attention of the principal railway companies, and we are authorised to state that the directors of the Great Western and London and South-Western Railway Companies have just decided to reduce the second-class fares generally over their respective systems, to a sum equivalent to about 1¼d. per mile, in the hope that this substantial reduction may induce many who would otherwise travel third-class to avail themselves of the second-class carriages. We are also informed that with a view to securing as far as practicable uniformity in the mode of caculating the first-class fares, the directors of the above companies have now determined to reduce the first-class fares to about 2d. per mile in all cases in which they are at present in excess of that amount. The exact date on which these alterations are to take effect has not yet been finally decided, as it will take some time to arrange the necessary details for giving effect to such important changes over the extensive systems of the two companies referred to.

The Leeds express on the Great Northern Railway got off the line last Saturday night. The settlement of a newly laid piece of line after a heavy fall of rain, taken with the great weight of the engine and tender, about 90 tons, are mentioned as causes. Two people were killed. Driver Guest is one of the oldest drivers in the company's service, and was in the Hitchin accident in 1869, when the York express ran over some sleepers, and in the Essendine accident in 1881, when the same train ran into a snow plough, and he was thrown into a goods wagon on the opposite line. He said the train was travelling down the incline between sixty and seventy miles an hour, when he felt a violent oscillation, and immediately called to the fireman, "We are off the road." His fireman applied the handbrake, and he shut off the steam, the train pulling up in 990 yards. Asked as to why the vacuum brake did not act immediately, he said it did. When the last carriage went into the parapet and broke its couplings the train quivered throughout its entire length, almost stopped, and then, with the brake on, skidded down the line, greasy with rain, like a skater going over ice, the sparks flying up and making it appear as if the train was on fire.

NOTES AND MEMORANDA.

In a recent paper on radiations emitted by phosphorescence, M. H. Becquerel describes an experimental proof of the fact that light emitted by phosphorescent substances possesses the power of affecting a photographic plate through a screen which is opaque to sunlight.

In a recent number of the *Comptes Rendus* is a paper on "The Carbide of Manganese," by M. H. Moissan. This carbide, Mn_3C, which is easily prepared in the electric furnace from Mn_3O_4 and sugar charcoal, differs from other metallic carbides in the simplicity of its reaction with water.

At the last meeting of the Physical Society, Sir D. Salomons showed some experiments with incandescent lamps. A large electro-magnet is excited by means of a continuous current, while an alternating current is passed through an incandescent lamp. On bringing the lamp near the magnet the filament is set in vibration, which is sufficiently intense to break the filament, if the lamp is brought near enough. The number and position of the nodes formed in the vibrating filament are found to be independent of the natural period of the filament, but depend on the frequency of the alternating current.

Of Russia's consumption of coal, 79 per cent. is her own coal, 17 per cent. is British coal, and 4 per cent. comes from other countries. In Sweden 88 per cent. of the coal consumed is British; in France, 12 per cent.; in Spain, 50 per cent.; in Austria-Hungary less than 1 per cent.; and in Italy nearly the whole is of British origin. The number of persons employed in coal production in various countries in 1894 was as follows:—United Kingdom, 665,747; Germany, 299,627; Belgium, 117,103; France, 131,587; Japan, 1893, 30,345; the United States, 1893, 363,309: British India, 43,197; Canada, 9654; New South Wales, 9131; New Zealand, 1899; and the Cape, 1601.

A question relative to animal mechanics was dealt with in a recent paper before the Paris Academy of Sciences on "The Relation between Muscular Work and the Albuminoid Materials of the Body," by M. A. Chauveau, which is an experimental study of the question as to whether albuminoids take part in the production of external work. The results show that the amount of nitrogen secreted is practically the same whether the animal is doing external work or not, and thus confirming the conclusion drawn by the author from previous experiments, that it is by the combustion in the muscle of carbohydrates that the energy necessary for external work is produced.

In 1894 the United Kingdom produced 188,277,000 tons of coal, Germany 76,741,000, France 26,964,000, Belgium 20,534,000, Austria 9,573,000, Japan—1893—3,371,000, and the United States 152,448,000 tons. Of the British Possessions, Canada produces between three and four million tons, and in addition imports about half her total consumption, principally from the United States. New South Wales produces about three and a half million tons, but, unlike Canada, her output has been of late years practically stationary. New Zealand yields over 500,000 tons per annum, but shows little or no increase. Natal's output rose from 26,000 tons in 1889 to 141,000 in 1894. Similarly in British India the production has steadily risen from 1,316,000 tons in 1883 to 2,821,000 tons in 1894. The countries which import coal in excess of the amount they export are Russia, Sweden, France, Spain, Italy, and Austria-Hungary; and of British Possessions, Canada, Victoria, Queensland, Tasmania, New Zealand, the Cape, and British India, together with all the minor Colonies with the sole exception of Labuan—Borneo.

Among the most recent and novel applications of wire, attention is drawn in *Hardware* to the wire fly-wheel, lately erected at the Mannesmann Tube Company's works, Germany, and especially notable in view of the well-known fact that heavy fly-wheels, driven at high velocities, present such dangers of breaking asunder from the great centrifugal force developed. The wheel at the factory mentioned is described as a cast iron hub or boss, to which are attached two steel plate disks, or cheeks, about 20ft. in diameter. The peripheral space between the discs is filled with some 70 tons of No. 5 steel wire, completely wound around the hub, the tensile resistance thus obtained being found to be far superior to that of any casting. This huge fly-wheel is driven at a speed of about 240 revolutions per minute, or a peripheral velocity of 2·8 miles per minute, or approximately 250ft. per second, which is said to be nearly three times the average speed of any express train in the world. For such a constructed fly-wheel the length of wire is estimated at about 250 miles. The use of paper is also regarded with favour for large fly-wheels, the tensile strength of paper being enormous, and it is quite possible that some of the new big wheels will be built up with a paper rim.

Mr. Henry Hall and Mr. Joseph S. Martin, two of her Majesty's Inspectors of Mines, have presented a report to the Home Secretary, which has just been printed, on the visit which they paid at the end of last year to Schalke, near Gelsen-Kirchen, in Westphalia, to investigate the experiments conducted there by Herr Bergassessor Winkhaus. The report contains a detailed description of these experiments, illustrated with reproductions from photographs. The inspectors think that the experiments prove, if further proof was needed, that the use of certain safety explosives in the stead of such explosives as gunpowder, dynamite, gelatine dynamite, gelignite, &c., would substantially diminish the risk of blasting operations in coal mines. English roburite appears to have been hitherto the most successful explosive. Legislation should not only specify the kind of explosive, but should also place a limit on the amount of charge and forbid its ignition except by electricity. It cannot be said that any safety explosive is absolutely safe; either ignition should take place "between shifts," in the absence of the workpeople, or the vicinity of each shot should be copiously watered. The inspectors add that gunpowder is entirely forbidden in mines representing about 80 per cent. of the total production—40,000,000 tons—of Westphalia. They recommend that a return should be obtained showing to what extent safety explosives are already in use in England with a view to their compulsory and general adoption.

In the discussion on Mr. A. A. C. Swinton's paper before the Society of Arts, on 4th inst., on the new photography, Mr. Brooks, of Reigate, drew attention to the fact that in March, 1877, he made a communication in that room to the South London Photographic Society with regard to non-luminous actinic rays, but he had no electric appliances, and used a horseshoe magnet. By exposing plates in complete darkness to the action of the magnetic field he obtained certain images, and found that even outside that there were invisible rays by which he could photograph through blackened cards, as had been shown that evening. But when he brought this subject forward, it was pooh-poohed, and so he let it drop. He would now renew his experiments, especially as he had seen some things now which explained what he could not then understand. He found that the rays he used were not due to magnetism, although associated with it; and he also found that he could even get rays from the fingers. In those days wet plates were universal, and a friend of his asked him for some chemicals and a bath to prepare some plates; he gave them to him, but next day his friend said they were useless, for every plate fogged. He himself then excited a plate, and exposed it, and found it perfectly clear, and so he came to the conclusion that there were some effect due to his friend's personality, and he proved this to be the case; for the placing of his friend's hand on the back of a plate was enough to fog it. In those days there were no pneumatic holders, and each plate had to be held by the corner, and on investigating the matter he found that in about 2 or 3 per cent. of cases rays were given off from the tips of the fingers, which shoot out 2in. or 3in.

MISCELLANEA.

Messrs. Laird launched on the 3rd inst. the second of the four 30-knot torpedo boat destroyers which they are building for the Chilian Government.

A Reuter telegram from St. Petersburg says that the Russian Admiralty has placed an order with the firm of Friedrich Krupp, of Essen, for the armour belt of the Poltava, the plates to have a thickness of 368 mm.

Amongst the new books announced by Messrs. Crosby Lockwood and Co. is one on light railways, by Mr. J. C. Mackay, A.M. Inst. C.E., and Messrs. Whittaker and Co. announce one on "Trade in the Far East," by Mr. C. C. Wakefield, F.R.G.S.

The £100 premium offered by the Marlborough Town Council for the best drainage scheme most suitable for the requirements of the borough has been awarded to Mr. G. Maxwell Lawford, Assoc. M. Inst. C.E., Westminster, and his scheme has been selected for immediate adoption.

The Imperial Russian Government having decided to lay down a considerable number of torpedo boat destroyers of the Sokol type—built by Messrs. Yarrow and Co., of Poplar—have invited that firm to co-operate with the Franco-Russian works for the construction of these vessels at St. Petersburg.

The Marylebone Vestry have decided to light Upper Regent-street with electric arc lamps. The cost will be £180 per annum, and the light equal to 6000-candle power; the present cost of gas—850-candle power—is £150 per annum. Upper Regent-street reaches only from Oxford-circus to the Langham Hotel, but has a considerable traffic.

The price of gas in Melbourne is 4s. 8½d., as against 4s. 6d. in Sydney and suburbs. The *Builder and Engineer* says, as larger steamers were employed between Melbourne and Newcastle than between Sydney and Newcastle, the difference in freight in favour of Sydney was trifling, and more than made up by the higher price obtained for residuals in Melbourne.

It is probable that the Government Bill dealing with the water supply of the metropolis, the pilotage of which through the House of Lords has been entrusted to Lord James of Hereford, will be introduced next week. The measures promoted by the water companies are down for consideration to-day, and the Government may be expected to assent to the second reading on the understanding that they shall be referred to a hybrid committee.

The officials at Devonport have received the programme of work for 1896-97. An improved Renown will be laid down on No. 3 building slip, on which the Arrogant is now in course of construction. The *Army and Navy Gazette* says that by the end of March, 1897, the Devonport, battleship, will be advanced to the extent of £125,772. The Arrogant is to be completed and the Furious is to be advanced. The Renown is to be completed for sea by June and the Talbot by May; the other item of new construction is the completion of the machinery of the Proserpine.

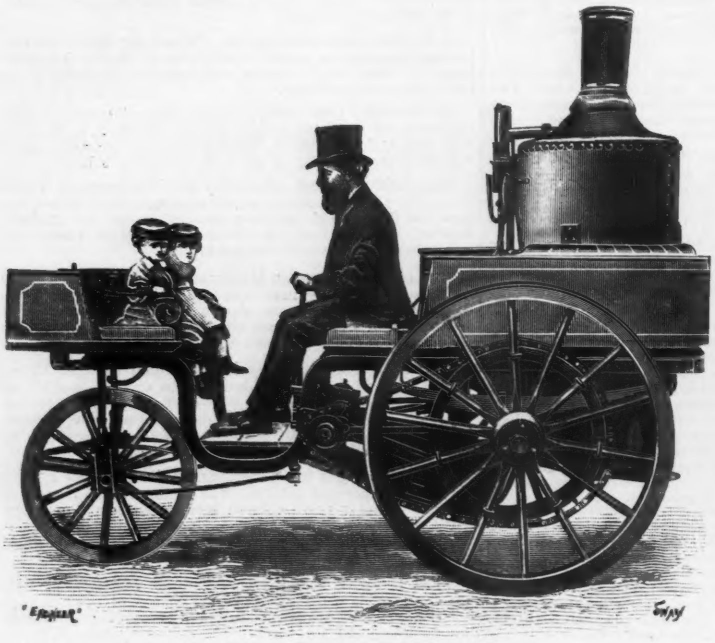
That "destroyers" of the Sokol type are finding favour with other than the Russian naval authorities, is evidenced by the fact that Messrs. Yarrow and Co. have now in hand at their works, and in an advanced state, four of that type of vessel—but somewhat larger—building for the Argentine Government. In these vessels—following the precedent of the Japanese Government—the machinery space will be partially protected by armour. All of them will be fitted with the Yarrow type of water-tube boiler. Messrs. Yarrow have also in hand at their works a number of water-tube boilers of their special type for various navies, the vessels for which are being built abroad.

The Admiralty have determined to solve the problem how to communicate effectually and promptly, not only between the bridge and the engine-room of a warship when she is steaming at high pressure, but between all parts of the ship. The *Naval and Military Record* says the service voice-pipe has long been condemned as a source of worry to all who have been called upon to use it, while the Admiralty have prudently hesitated before introducing the telephone, except in such parts of a ship as are not disturbed by the rattle of machinery or affected by electric currents. During last year's manœuvres the Homacoustic voice pipe was tried on the cruiser Fox, and although it was not a success at first, it was found that when three seamen from the deck and three stokers from the engine-room—one of each rating to serve in each watch—had become acquainted with each other's voices, the sound could be satisfactorily heard. Since then the apparatus, which has been so improved upon as to absolutely insulate the sound, has been tried with good results in the torpedo boat destroyers, and the company is now putting in an installation in the Eclipse, which is to have her trials in May. One side of the ship is to be supplied with the service voice-pipe, and the other side with the Homacoustic apparatus.

Particular attention is being drawn now to the woods of the South American colony of British Guiana, and especially to the Greenheart, which as sawn timber is being largely introduced into this country by the Berbice Steam Saw-mill Company, and used for platforms, brewery floors, and other places where the well-known weather and water-resisting qualities are of great value. Greenheart has long been looked upon as an expensive timber, but necessary to some kind of engineers' work, and it seems almost strange now to see it used for the more commoner purposes. Among other British Guiana timbers now being sent out in various sawn scantlings by the company may be mentioned Bullet Tree or Beefwood, Mora, and Wallaba, which are in some respects second only to Greenheart. Like that timber, Bullet Tree or Beefwood is very hard and durable, and is suitable for resisting great wear and tear. Mora is recommended for railway work, for wood blocks for street paving and for other purposes. In British Guiana it has been found to answer well in the construction of sleepers, having proved very durable. It costs less than Greenheart. Wallaba is used very extensively for vat making in connection with the rum industry on the sugar estates, and would, it is said, answer well for brewery vats. The Berbice Saw-mill Company have offices in London, and Messrs. Whitbread and Co. have used their Guiana timbers for several purposes.

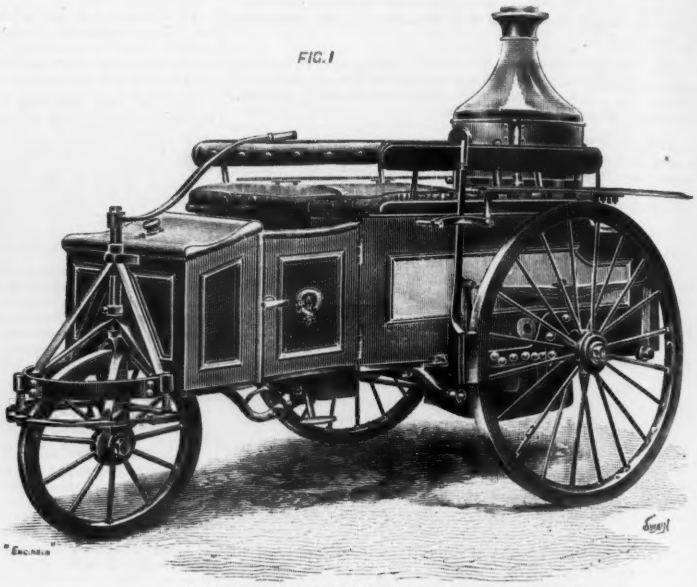
The opening ceremony of the Howrah waterworks took place on the morning of the 8th ult. The works are designed to furnish the municipal town of Howrah, having a population of 125,000, with a water supply of 10 gallons *per capita*, or a maximum of 1,250,000 gallons per day. The water is taken from the river Hooghly at Serampore, where the pumping station is located, and after passing through the usual settling tanks and filter beds is pumped into three raised reservoirs in the town of Howrah, from which it is distributed throughout municipal limits by thirty-seven miles of iron pipes varying in diameter from 16in. to 2in. The water is served to the public by 240 standposts. The supply pipes to the elevated reservoirs are so arranged that in the event of accidents or damage to any of the reservoirs, the supply to it can be cut off from the main, and continued to the distribution pipes direct by a by-pass provided with the usual fittings. The pumping plant consists of two duplicate sets of compound condensing direct-acting steam pumps of Messrs. Joseph Evans and Son's well-known duplex type. The engines for the suction and delivering into the filter beds have steam cylinders of 8in. and 14in. diameters and a stroke of 18in., while those for the filtered supply have cylinders of 11in. and 20in. diameters with a piston stroke of 12in. Steam is supplied to both sets of pumps by three Lancashire boilers.

SOME HORSELESS CARRIAGES



HOLT'S STEAM CARRIAGE, 1867

FIG. I



CATLEY AND AYRES' STEAM WAGONETTE, 1863-67

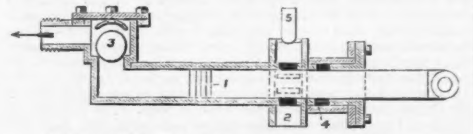
SOME HORSELESS CARRIAGES.

IN our impression of the 7th ult. a description was given of the steam carriage designed and made in 1866 by Mr. H. Percy Holt, a carriage in which there are several points of interest in connection with the engines and their gear and arrangements. This carriage was subsequently sold to Mr. S. G. Rhodes, who had previously been making a carriage which we now also illustrate. Mr. Rhodes of this carriage says it was one he "began to build in 1863," and that, "when completed, it did some very fair running. At first it was direct action on four wheels, and not satisfactory, but when altered to the form as shown in the drawing, it ran splendidly on any road and over new metal."

He also bought the steam carriage from Mr. Holt, and of this he sends us the photograph we now reproduce. Mr. Rhodes made some alterations in it, including the lap of the valves and the position of the excentrics. And writing from the works of Messrs. Rhodes Bros., mechanical and electrical engineers, Hanover Works, Leeds, Mr. Rhodes says:—"The photograph shows myself and twin sons on Holt's carriage a quarter of a century ago; Rhodes Bros. are the same twins." Referring to the pump mentioned in our notice of Mr. Holt's carriage, Mr. Rhodes sends a sketch, from which the annexed engraving is made, saying that he had previously used it on his own carriage.

In this engraving 1 is the plunger with rings on the end; 2, a cage round pump barrel over the slots with water inlet pipe 5; 3, ball delivery valve; and 4, packing, which had not any pressure to withstand.

Of this pump he says:—"This pump, when running quickly, would lift water in a state of ebullition 3ft. and force into boiler at 150 square feet. The plunger bared the slots at the end of the stroke, where it was moving slowly and coming to a stop; the pump never failed."



FEED PUMP OF HOLT'S STEAM CARRIAGE

Of his own carriage Mr. Rhodes sends the drawings, from which it appears that the two cylinders are connected to one crank shaft with cranks at right angles, and with a chain pinion on each end driving the road wheels, to which chain wheels are attached to the spokes. Both wheels are equally driven, no arrangement being provided for turning corners. Subsequently the crank-shaft was separated into two lengths, and each engine ran independently, thus allowing for corner turning. The frame was made of 4in. by ¼in. flat iron, with a 1½in. angle riveted to the top edge, and was carried on three wheels, two driving-wheels 5ft. diameter by 3in. face, and one steering-wheel 3ft. diameter by 3in. face, strongly made of oak, and steel-tired; between the driving axle and frame were long leaf springs, connected with radius rods to the engine crank shaft; the front wheel was carried by a fork fitted with sliding bearings supported on spiral springs and connected by links to the steering handle.

The boiler was 2ft. diameter by 3ft. 6in. high, and had seventeen Field tubes and thirty-six flue tubes into smokebox, and worked at a pressure of 150 lb. per square inch. The engines were placed one on each side of the boiler, and had cylinders 3⅛in. bore by 9in. stroke, and geared 5 to 1 to the driving-wheels by means of pitch chain.

The feed pump, which was worked from one of the engine crossheads, was specially designed, and probably the first of its kind, made to lift and force boiling water, and had only one valve. A feed pump made to this design was afterwards fitted to Mr. Holt's steam carriage.

Part of the exhaust steam was turned into the water-tank to heat the feed, the remainder into the chimney, and rendered noiseless by means of a double cone blast nozzle. All the machinery was completely enclosed, and the carriage ran successfully for many years without any serious accident or complaint, and would make from twelve to fourteen miles per hour with ease.

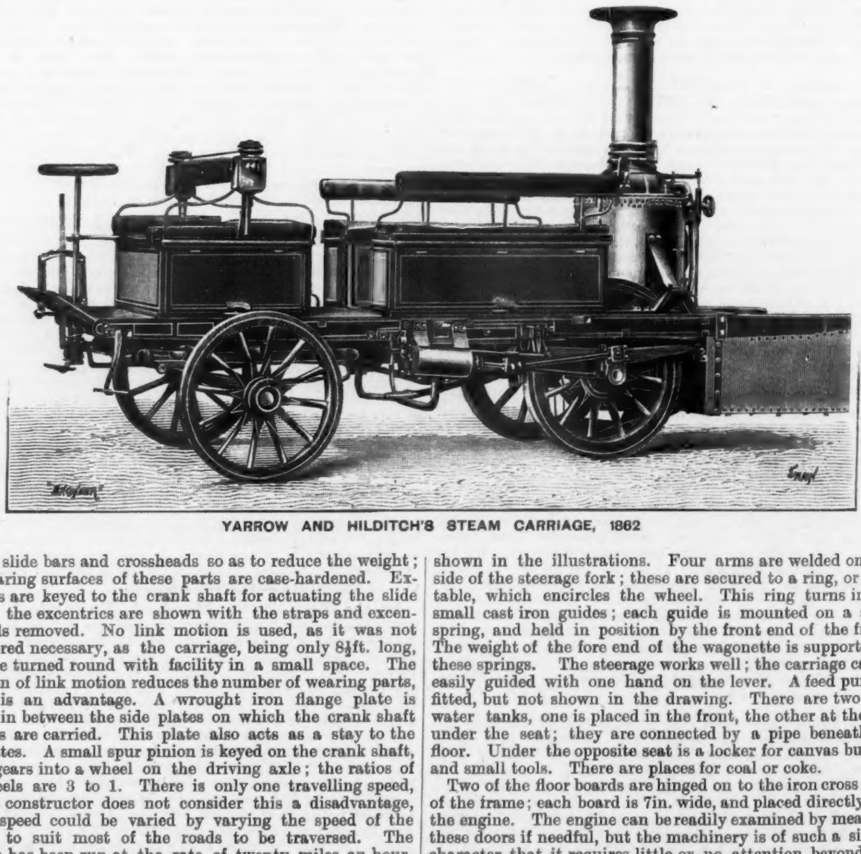
In further addition to the steam carriages which have recently appeared in THE ENGINEER, there is another of merit yet to be described. This vehicle was made in 1869, by Messrs. Catley and Ayres, who exhibited it at the Yorkshire Agricultural Society's meeting held at York in 1871, and has only been briefly referred to in any publication.* There are several interesting features embodied in this carriage deserving a full description, which at the present time cannot fail to interest many of the readers of THE ENGINEER.

The wagonette is illustrated by the above engraving from a photograph. On page 265 is a plan of the machinery, with the carriage body removed, and a side view of the same. The frame is made of bar iron 3¼in. deep and $\frac{5}{16}$in. thick, bent to the shape required, and the ends welded together. About the middle of the frame there are two pieces of tee iron, and there are transverse bars in other parts for stiffening the structure. The horn plates for the axle-boxes and the deeper plate for the cylinders are welded in the frame, as shown on page 265.

The carriage is propelled by a pair of horizontal engines, driving a short crank shaft with the two cranks placed at right angles to each other. The cylinders are 2⅜in. diameter, and 5¾in. stroke; the piston heads are forged with the rods. The pistons have grooves cut in them for two steel rings; each ring is $\frac{3}{16}$in. wide and ⅛in. thick. Wrought iron is used for the slide bars and crossheads so as to reduce the weight; the wearing surfaces of these parts are case-hardened. Excentrics are keyed to the crank shaft for actuating the slide valves; the excentrics are shown with the straps and excentric rods removed. No link motion is used, as it was not considered necessary, as the carriage, being only 8½ft. long, could be turned round with facility in a small space. The omission of link motion reduces the number of wearing parts, which is an advantage. A wrought iron flange plate is riveted in between the side plates on which the crank shaft bearings are carried. This plate also acts as a stay to the side plates. A small spur pinion is keyed on the crank shaft, which gears into a wheel on the driving axle; the ratios of the wheels are 3 to 1. There is only one travelling speed, and the constructor does not consider this a disadvantage, as the speed could be varied by varying the speed of the engines to suit most of the roads to be traversed. The carriage has been run at the rate of twenty miles an hour, and has travelled up gradients of 1 in 20.

The hind axle is 2in. in diameter; the bearings are made of cast iron sliding in the iron plates; the weight of the hind part of the carriage is passed to these axle blocks through long plate springs, as shown in the engravings. As the crank shaft and main axle are on the same horizontal centre line, the up-and-down motion of the axle caused by the action of the springs will not affect the spur wheels very much, if the movement is not excessive. An arrangement like this has been used on one maker's traction engines for many years without any serious inconvenience.

The driving wheels are 3ft. 6in. in diameter; the twenty spokes in each wheel are made of ½in. round iron, with collars forged on the outer ends faced in the lathe, and chased on the ends beyond the collars, as shown in Fig. 3. The ends of the spokes are screwed into a 2in. by $\frac{5}{16}$in. wrought iron hoop, and into the ash tire also; the felloes are dowelled together with iron pins. At this stage the wheels were sent into the foundry to have the bosses cast on, afterwards they were bored and faced in a lathe; the wood tires were also turned on the sides and on the outer edge. The outer hoop was next shrunk on; it is made of 2in. by ½in. iron. It will be seen that the inside hoop, the wood tire, and outside hoop are riveted together. This makes a light and satisfactory wheel. One of the driving wheels is keyed to the axle, the other runs loose so as to facilitate turning. The front wheel is 2ft. in diameter, and is made in the same manner as the hind wheels; the leading wheel runs in a fork, the spindle of which turns in a double guide of light wrought iron; the guide is riveted to the fore part of the frame, as shown in the illustrations. Four arms are welded on each side of the steerage fork; these are secured to a ring, or turntable, which encircles the wheel. This ring turns in four small cast iron guides; each guide is mounted on a spiral spring, and held in position by the front end of the frame. The weight of the fore end of the wagonette is supported by these springs. The steerage works well; the carriage can be easily guided with one hand on the lever. A feed pump is fitted, but not shown in the drawing. There are two feed-water tanks, one is placed in the front, the other at the side under the seat; they are connected by a pipe beneath the floor. Under the opposite seat is a locker for canvas buckets and small tools. There are places for coal or coke.



YARROW AND HILDITCH'S STEAM CARRIAGE, 1862

Two of the floor boards are hinged on to the iron cross stays of the frame; each board is 7in. wide, and placed directly over the engine. The engine can be readily examined by means of these doors if needful, but the machinery is of such a simple character that it requires little or no attention beyond the lubrication of the working parts. The driving wheels are fitted with lever hand brakes, as shown.

The boiler is of the vertical fire-tube type, constructed of Lowmoor iron plates. It is 3ft. high, and 17½in. external diameter. The shell plates are $\frac{5}{16}$in. thick, and the tube plates are $\frac{7}{16}$in. thick. A spiral tube superheater is fitted in the smoke-box made of 1½in. piping; the steam passes through this coil on its way to the engine cylinders. The iron smokebox and chimney are covered with a polished copper casing. To prevent the radiation of heat, the boiler is coated with a

PLAN

CATLEY AND AYRES' STEAM WAGONETTE

RHODES' STEAM CARRIAGE

thickness of non-conducting material, and polished mahogany lagging outside. Mr. Catley tested the boiler with water up to 400 lb. pressure per square inch. The working pressure is 150 lb. By using good coal very little smoke was made, but coke could be used if required. The boiler supplied dry steam, and the engines are set to work with an early cut-off. The passage of the exhaust steam into the chimney base causes very little noise, and therefore was not suppressed. Twenty gallons of water and about 2 cwt. of fuel can be carried.

The engine made many journeys during three years, carrying four passengers for eight or ten miles round York; the speed could be increased up to about twenty miles an hour on good level roads, and slower rates of speed were attained on gradients. Little noise is made by the carriage when travelling; there is no vibration whatever, and Mr. Catley says, "The horses they met during their numerous journeys took no notice of it."

An important feature of this steam wagonette is its very moderate weight. When the boiler, tanks, and bunkers are full, ready for a run, the total weight was only 19 cwt. Among the objections urged against the steam engine for carriage propulsion the supposed weight is always dwelt upon. But this example appears to show that with careful designing a steam carriage of substantial construction, and well adapted for hard work, need not necessarily be as heavy as many that have been built. The reduction in the weight is secured by the use of light bars of wrought iron for the frame. No cast iron is employed except where it is absolutely necessary, and when it is used the parts are made as small as possible. The driving gear is simple. The use of one speed cuts down the number of parts, and although in respect of the driving of only one wheel, and in small details improvements could easily be now made, it will be admitted that Mr. Catley's carriage presents several features of interest.

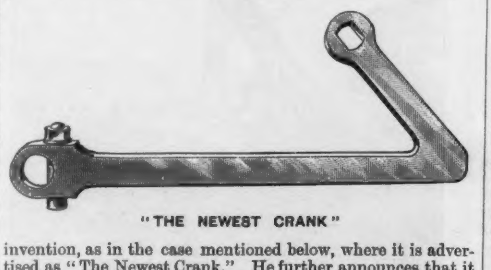
Brief descriptions and some illustrations have been published of Yarrow's steam carriage, exhibited in the 1862 exhibition by Messrs. Yarrow and Hilditch. We now publish an illustration made from a photograph placed at our disposal by Mr. A. F. Yarrow, and the following description is from a paper read by Mr. Yarrow before the Society of Engineers:—

"It is made to carry thirteen persons, including a steerer and a stoker. The steerer sits in the centre of the front seat, having one passenger on each side. Back to back with them are seats for three others, and for six more—three on each side—facing each other. By this mode of arranging the seats, it can conveniently be covered in, with a door on one or each side for entrance. The stoker is placed in the tender behind. The boiler is of the ordinary upright tubular type, the outside shell being steel. It is 2ft. diameter and 3ft. 9in. high; it has 40 square feet of heating surface, and a fire-grate 21in. in diameter. It is fitted with a perforated steam pipe round the top to reduce the chance of priming. The main framing of the carriage is ash, 4½in. deep, lined with edge plates ¼in. thick. To the outsides are bolted two iron foundation plates for carrying the cylinders, &c. On the inside of the framing are the driving wheels, which are 3ft. diameter; they have a cast iron boss similar to Crosskill's, and are both keyed on the main driving axle; on the outside of these wheels come the bearings which carry the springs; beyond these are fixed the cranks, to which one end of the connecting-rod is attached. The advantages claimed for thus arranging the parts are:—'That the gauge of the hind wheels being considerably reduced, does not necessitate throwing the inner one out of gear when turning curves; and, secondly, that direct action is obtained without having the axle cranked, which past experience has shown to be highly objectionable, as the continuous jolting very soon breaks it.'

"In order to keep the axle in its right position, a link is employed in preference to axle-box guides, as, by its use, far less friction is caused, and the distance between the shaft and cylinder is maintained precisely the same, and the action of the valves remains unaffected by the vertical play of the springs. One end of the link is connected to the axle bearings and the other to a provision on the foundation plate. The working parts are entirely boxed in to protect them from dust and grit. The cylinders are 5in. in diameter and 9in. stroke. When fully loaded the weight is 2½ tons; about 40 cwt. is carried on the hind wheels, and 10 cwt. on the front ones."

CYCLE MECHANICS.

IT has long been obvious that ordinary mechanical principles are things which many cycle inventors regard as inapplicable to cycles, and as mere trammels which prevent new developments. It is true the same inventors usually bow to these principles later, but in the meantime the public is sometimes taken into their confidence, with the result that public and inventor find out together that mechanical laws are most expensive when most ignored. It is not often that an inventor who defies these laws, so correctly names his invention, as in the case mentioned below, where it is advertised as "The Newest Crank." He further announces that it is protected, and says, "By this arrangement power usually wasted in the endeavour to get away from the centre or axle is utilised to create a circumferential movement, the efficient length of the crank is increased some 20 per cent., the traverse of the foot remaining the same. There being practically no dead centre, a perfectly even movement is obtained." We hope no steam engine makers will be caught infringing "The Newest Crank" patent.



"THE NEWEST CRANK"

SAFETY APPLIANCES FOR PETROLEUM TANKS.*

THE destruction by fire of the petroleum tank storage at Harburg in May last has directed attention to the subject of petroleum tanks, and the danger likely to accrue to the community from their situation in inhabited districts. The report on the Harburg fire, drawn up by M. Albrecht, tended, however, to dissipate the alarm at first occasioned by the catastrophe, by bringing to light the fact that the fire was not due to any specific danger inherent to the use of tanks for storage, but to defective appliances whereby a large volume of an explosive mixture of gas and air was enabled —under the favourable atmospheric conditions, viz., absence of wind, prevailing at the time—to collect above the cover of the tanks, and facilitated—or, at least, did nothing to hinder—the passage of the flames ensuing, when the mixture was ignited by lightning, into the interior, and so firing the inflammable gaseous mixture existing therein above the surface of the oil.

In considering how similar accidents can be guarded against, three main questions arise, viz., how can the tanks be protected against ignition: (1) by lightning, (2) by communicated flame from another fire, and (3) how may the danger of explosion be obviated? For the proper understanding and appreciation of the last question it must be recollected that the air space above the oil is filled with a mixture of gaseous hydrocarbons and air, the proportions of which mixture are liable to continual variation from the expulsion of mixed gas and the inflow of air occasioned by the alternate expansion and contraction due to changes of temperature. To return to the protection of tanks from lightning; it is requisite that an efficient installation of conductors must be provided. This can be carried out most suitably by the erection of four rods about 30ft. long, connected at about 16ft. above the lid of the tank by a copper cable of appropriate diameter; this will divert the course of a flash striking between the vertical rods. The system should be grounded to a network of pipes—gas or water pipes—or else to a copper plate of suitable dimensions sunk in the soil water, particular care being taken that all the connections are sound and protected by an efficient covering to shield them from atmospheric and other influences. The rods, cable, and ground plate will, of course, require to be capacious enough properly to conduct the electric current to earth, and the periodical examination of the condition of the installation is absolutely essential, especial care being needed to see that the weak points, viz., the connections, are in thorough working order. Measuring the resistance by means of the ordinary apparatus is not sufficient to detect other than large faults in this respect.

In the second point under consideration, the object in view is the prevention of the transference of flame from the external air into the gas space in the tank, and the most efficient method of effecting this is by making the ventilator tubes of a U form, the longer limb projecting through the edge of the tank lid downwards for a few feet, and being provided with three partitions of fine wire gauze—120 meshes to the square centimetre. This downward direction of the tubes will prevent the accumulation of heavy hydrocarbon gases on the cover of the tank. The ventilators will need to be of large diameter to allow ready escape of air during the filling the tank, and may conveniently be enlarged at the points where the partitions are inserted, in order to diminish friction.

The efficiency of this method of protective ventilation has been thoroughly tested on a small scale by the author, who found that the evolved gaseous mixture from petroleum heated in a current of air burned quietly away beyond the gauze interceptors, so long as there was gas to consume, but that, notwithstanding the varying proportions of the mixture—from saturation with gas down through the various degrees of inflammability and explosibility to attenuation—no lighting back behind the gauze occurred.

So far as reducing the effects of an explosion to a minimum is concerned, the chief precaution to be adopted is to make the tank cover as light as possible, and provide a liquid seal—glycerine or similar fluid—at its junction with the body, taking care that the cover cannot be carried away by the wind, and that it is in electrical connection with the lightning conductors.

The value of such appliances in the tanks as steam pipes—or, as has also been proposed, for places where steam is not available, carbonic acid apparatus—for the extinction of fire, is still problematical; but there is no doubt that the provision of a sound wall or embankment around the tanks is highly essential for the prevention of the outflow of burning oil, and not only would the risk of this be still further reduced by the introduction of a series of channels converging to a main leading to a spacious collecting basin at some little distance away, but the chances of saving a great part of the oil in case of fire would be notably increased.

SWALES' SPOON DREDGER.

In many situations and for some kinds of work a spoon dredger is the most effective machine. That which we illustrate by the accompanying engraving is the invention of Mr. W. Swales, Shoreham, and was used for years in connection with the Bournemouth and Boscombe sewage outfall works, for which Mr. Swales was the contractor. It was built by Messrs. Courtney and Birkett, of Southwich, Sussex.

Fig. 1 is a side elevation of the dredger, showing the bucket at various positions during the action of dredging. The dotted one marked A shows when the bucket is lowered and all ready to commence the cut. B shows the same after the end of the cut when the bucket has been hauled to the lowered gantry. C shows the bucket partly raised by the continued hauling in of the chain by the winch, and the radius described by the rising of the gantry, and at the point where the horns or projections H on the gantry are about to pass under the bridle of the bucket which keep it raised when over the shoots. D shows the whole in position ready for slacking back the hauling chain, and consequent opening of the hinged bucket bottom, allowing the discharge of spoil into the shoots. O is the chain used for holding the gantry in position when lowered. It takes the pull due to the force required to make the cut, and is worked from a roller winch controlled by a hand brake.

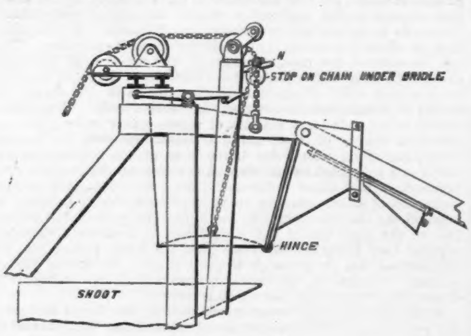

Fig. 2 is a side elevation to an enlarged scale, showing the arrangement and position of bucket over the shoots. Fig. 3 is a plan of this. Fig. 4 is an end elevation, and Fig. 5 is a longitudinal elevation partly in section of the dredger, showing the arrangement of steam winch and method of the driving screw propeller from it, and the universal joint for lowering or holding up the propeller, as may be required. Fig. 6 shows a plan of the gearing between the main winch shaft and the propeller shaft. When not dredging the dredger will make five knots an hour. It will do ordinary dredging in any depth from 3ft. to 30ft., lifting from 15 to 20 tons per hour, and discharging into hoppers or barges on either side. The water for clearing the bucket and shoots, it should be remarked, is discharged direct into the bucket by a pair of semi-rotary pumps worked by the main engine.

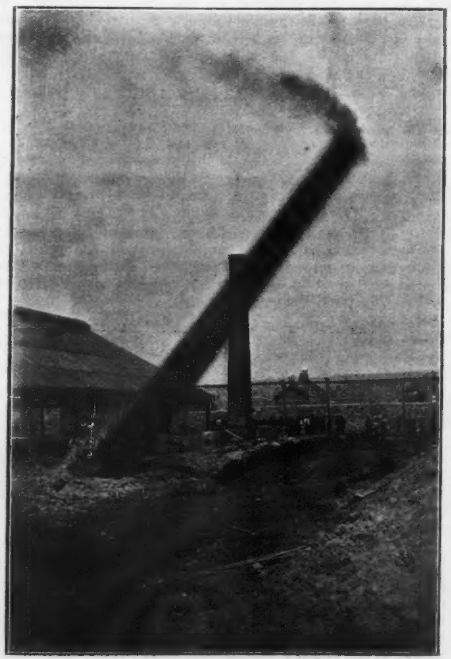
The Society of Arts.—In connection with the Indian Section of the Society of Arts a meeting is to be held at the Imperial Institute next Thursday evening, the 19th inst., when a paper will be contributed by Mr. J. H. Glass, C.I.E., on "The Great Landslip at Gohna, in Gurhwal." The chair will be taken at half-past eight o'clock by Sir Charles H. T. Crosthwaite, A.C.S.I., Member of the Council of India.

LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

DEMOLISHING CHIMNEYS.

Sir,—Referring to the illustrated article in your issue of February 28th, where you describe the demolition of a brick stalk in Manchester, I enclose you a photograph of a similar operation carried out by myself here in the year 1883. I proceeded in precisely the same manner in preparing the stalk as described in your article, and you will observe the smoke issuing from the top of the chimney from the fire which burnt away the supports. In these days instantaneous shutters were scarcely so highly developed as they are at present, and hence the image is somewhat hazy; the photograph was taken immediately before the final collapse took place. I did not take precise measurements at the time, but I remember remarking how small a space the fallen bricks occupied, and how suddenly the stalk collapsed and fell apparently vertically to the ground at the end of the operation. The collapse, if I remember rightly, took place at an angle only a few degrees greater than shown in the photograph. The method was not original on my part; I had heard of it being done some years before, but without details. I think that with the modern instantaneous shutter Mr. Smith might get some most interesting photographs taken at regular intervals during the falling of some large chimney. The eye is so apt to be deceived by operations of this nature which take place almost instantaneously.



I hope this photograph may be of interest to your readers.

Dumbarton, March 6th. A. Denny.

AMERICA AND THE BESSEMER PROCESS.

Sir,—Judging by the claims that have been put forward for Mr. Kelly as against Sir Henry Bessemer in the annual presidential address delivered at the recent Pittsburg meeting of the American Institute of Mining Engineers by Mr. J. D. Weeks, it would appear that this gentleman is very desirous to make amends to the Spanish nation for the action of the Americans in the matter of the Cuban revolution. Such, at any rate, must be the opinion of those Spaniards who regard their country as the birthplace of steam navigation. For if Mr. Weeks's arguments are to prevail, then the fame of Blasco de Garay must eclipse that of Robert Fulton, and with so much greater justice in this case as 260 years exceed 7, the number of years by which Kelly is said to have anticipated Bessemer's discovery.

If claims to inventions are to be wrested from those to whose names they are attached by the method of Mr. Weeks, it will fare badly with other inventors besides Sir Henry Bessemer, Kelly himself among the number. Turning, for example, to patent No. 3944 of the year 1815, we find mention of metal not being sufficiently decarbonated, or "not high enough blown," which, by the logic of Mr. Weeks, is clearly an anticipation of all subsequent pneumatic processes.

A. L. Holley's name occurs many times in the presidential address referred to, and apparently to give weight to Kelly's claim, or the claim made for him. Like other authorities, however, this one may be cited on either side. Speaking at Washington, D.C., on February 22nd, 1876, when Holley worthily occupied the very office now held by Mr. Weeks, he said to the assembled mining engineers, "Proceeding upon a chemical knowledge little superior to that of the average schoolboy, Bessemer developed his revolutionary process." No mention is made of Kelly in the whole of this address. How obscure Kelly's experiments must have been, and that they can have had no influence on the industry may be inferred from numerous references that were made as to the source of Holley's knowledge over his grave.

At the memorial session of the same Institute, now presided over by Mr. Weeks, held at Washington February 22nd, 1882, Mr. A. S. Hewitt, an ex-president of the Institute, said, "I think that I first called his—Holley's—attention to the Bessemer process, I mean to the subject of its introduction into this country. My firm had made a feeble effort within six weeks after the famous Cheltenham paper was read in 1856, to see whether pig iron could be thus converted into steel. It was three or four years, perhaps, after that that Mr. Holley's attention was called to the matter, and he went to Europe and brought back for his friends the control of that patent." It is strange Kelly's fame at this time should have been so obscure, if his achievements were what Mr. Weeks would wish us to infer.

Mr. P. Barnes, of Springfield, Ill., speaking at the same meeting, said, "My acquaintance with our good friend Holley began just before he went abroad to arrange for the definite introduction of the Bessemer process into this country, and after January, 1869, I was, until the day of his death, almost continuously employed, either as an *attaché* of his own private office, or else in local charge of some one or other of the works with which he was associated. . . ." No mention is made by Mr. Barnes, who was so intimately connected with Holley in the Bessemer industry, of any inspiration derived from Kelly.

I cannot find any reference to other than English practice as the starting point of that marvellous American development of the Bessemer industry, from which no one who is acquainted with it can withhold admiration.

At the memorial session of the American Society of Mechanica Engineers, held at Philadelphia on April 19th, 1882, Mr. James C. Bayles said, in his "tribute" to Holley, "We cannot fail to find interesting how this—present extent and prosperity of the industry—was brought about, chiefly by Holley's persistent industry and close study of details. Fully impressed with the possibilities of the Bessemer process, as he had witnessed its workings in England, he inspired others with his own enthusiasm." And again: "Early in the history of this industry Holley seems to have concluded that the best foreign practice was merely a starting point for an ingenious American engineer to work from." And yet again: "Bessemer probably has more claim to recognition as a great inventor than Holley; but if we compare the two men we see strikingly exemplified the difference between the inventor and the industrious engineer. Where Bessemer left the process which bears his name, Holley's work began. It was full of possibilities." . . . No disposition is shown by any of the speakers to give Bessemer one particle more than they thought his due, but the origin of the invention is never denied him.

Mr. J. C. Hoadley, of Boston, Mass., also said at the same meeting: "A few years later—in 1863—I met him, Holley, in London. He was seeking at that time to make arrangements with Mr. Bessemer for the manufacture of Bessemer steel in this country. With a perspicacity entirely characteristic of the man, he had perceived the transcendent importance of this invention, which was almost unnoticed by the world, and before Mr. Bessemer had ever received a shilling of legitimate compensation for his invention." And further on: "In that stage of the invention Mr. Holley, perceiving its great importance, with his own true-hearted loyalty, went directly to the man who had invented the process to get at the very limit—the utmost outpost of the invention; and we all know how much further he has carried it." Can stronger evidence be adduced in repudiation of Kelly's claim? F. J. R. CARULLA.

84, Argyle-terrace, Derby, March 10th.

RAILWAY ECONOMICS.

SIR,—Pending the further information promised by Mr. Tratman, I am content to leave the question of rail sections as it now stands in your correspondence columns; but concerning what has been called "building for posterity," Mr. Tratman sums up his view in a sentence more oracular than practical, which invites remark, particularly in view of light railways at home and new lines in external dependencies, both involving the question of State aid.

He says, "The underlying principle of colonial railways should be the construction of the greatest mileage at the least cost and in the least time; 'least cost' being, of course, considered in relation to the prospects of immediate or delayed increase in traffic."

It seems to me that the whole issue depends on the relative attention bestowed at the cutset upon immediate and delayed traffic. In the opening up of a new country the first lines constructed are likely to become the main trunks of the future, for two reasons: (1) They will, from commercial considerations, be located to serve the more developable districts, and planned to follow the easiest routes in conformity with the lay of the land. (2) The fact of their presence will stimulate activity in their neighbourhood, and create tributory traffic, and so pioneer lines will reap the advantage of being early in the field; an advantage which, in the plenitude of harvest, we may be too prone to ignore in our old country.

With these probabilities of pioneer lines becoming eventually main trade routes in a busy country, to lay them out on the principle of least cost for immediate traffic would be very false economy. A bad road cannot be transmuted into a good road easily or cheaply, and the more the necessity for reconstruction the greater becomes the difficulty of amendment as traffic increases. Initial mistakes are thus likely to be perpetuated, to the detriment, not only of the undertaking, but of the country.

This is the point which seems to be overlooked by Mr. Tratman, and generally avoided, as is, perhaps, natural when immediate dividends are the first consideration, or when capital is insufficient. It is the dividing point between true economy and makeshift expediency, and possibly also a point at which Government interference may assist commercial enterprise.

There is little fundamental difference between the economics of railways and common roads, and I fear we have forgotten the immense influence of the old coach roads made by the Romans, or after their example, in developing our own country. If our ancestors had been satisfied to let roads evolve themselves, on the principle of immediate requirements, by filling up ruts and holes now and then, there would not have been money or enterprise enough in the whole land to build the first railway. At the present time, however, the great results of this imperial interference are thought of no more than the rotation of the earth, and other familiar institutions, which in a vague way we credit to Providence, when it occurs to us to think of them at all.

The parent question concerned permanent way only, but future requirements ought to be kept in view when curves and gradients are determined for a pioneer line. With light railways having no expectation of great traffic, permanent way is, perhaps, of even greater moment as a factor in true economy, although in a rather different sense. Here the main object should be to construct a road requiring the least outlay in renewals, and the least daily attention; and therefore wood should be excluded altogether, both for sleepers and keys. For light traffic metal keys may be made perfectly efficient; and with steel sleepers and light double-head rails—with their advantage in stiffness which has been pointed out—a track may be constructed which will require the minimum of maintenance.

Whether we regard pioneer railways with their potential importance, or light lines with their slender incomes, the necessity of adequate outlay in the beginning is alike apparent if we consider economy in its proper sense. It is the duty of the State, and the policy of great corporations, to consider posterity; and the power of capital possessed by both can never be more beneficially exercised than in founding reproductive works on the ancient Roman system of doing things well. JAMES WHITESTONE,

113, Queen Victoria-street, E.C., February 25th.

ENGINEERS FOR THE NAVY.

SIR,—The 200 engineers proposed to be raised to 300 are those of the Naval Reserve—see end of paragraph 3 under the heading Royal Naval Reserve, page 5, Statement of the First Lord of the Admiralty, explanatory of the Navy Estimates, 1896-7—but as this force has been nearly stationary for the last two years, this increased number is not likely to be obtained.

The statement that the number of applicants is such as to meet the necessary requirements of the service is as inaccurate, misleading, optimistic, and at variance with the facts as official utterances on this subject usually are. At the end of the year 1894-5 the number of engineers were 773, a deficiency of 12 on the strength of the establishment. The Navy Estimates for 1895-6 provided an additional 53, bringing up the extra number required to 65.

The above statement of the First Lord of the Admiralty gives the idea that these 65 engineers have been obtained, but this is not the case; the number obtained are but 27, all assistant engineers for temporary service, entered at a greatly reduced standard. The deficiency, which at the end of 1894-5 was 12, has thus risen at the end of 1895-6 to 38. The Navy Estimates for 1896-7 provide for 850 engineers, an increase of 12 on the estimated numbers for 1895-6, and of 50 on the present numbers. The incorrectness of the First Lord of the Admiralty's statement as to engineers throws doubt on those as to engine-room artificers and stokers. If statements which can be rectified turn out incorrect, what is likely to be the case as to those whose accuracy the public have no means of testing? C. P.

Westminster, S.W., March 10th.

PRIOR PUBLICATION OR NOT.

SIR,—The further facts stated by "J. H." do not assist him. The question in the third paragraph of his letter is clearly settled by Fry, L. J., in the case quoted in my last letter in your issue of February 28th. It follows from that judgment that if the public became possessed of an invention through fraud, they cannot be estoppel of the user of the invention by them, because the means they became possessed of the invention were fraudulent and the public cannot be charged with fraud. "J. H." makes no point in the words "mere inspection," for he cannot gauge the psychological capacity of the person who inspects; the plan of the invention may flash upon one man's mind, whilst another arrives at it by a slow logical process.

In Lang *v.* Gisborne, Ch. (1862), the Master of the Rolls states, "I am of opinion that it is not at all necessary to establish the fact that one volume of that book was sold, for I think that as soon as an inventor informs the public of what his invention is and prints it in a book, which he sends to a publisher to sell, from the moment that the book is exposed for sale in the bookseller's shop, there becomes, in point of law, a complete publication of the invention." The book was written in French.

This goes much further than "J. H.'s" case. People have seen "J. H.'s" full-size working model, no one need have seen the inside of the book. But it is hardly possible in a letter to give more than general outlines of the law. Each case has some peculiar feature that is important, and which may be overlooked by the non-expert in such matters, but which would, if known, influence any opinion given. Some points in the case of Lewis *v.* Marling, 1829, are pertinent to "J. H.s" facts. But this case would have to be considered, as against this in Carpenter *v.* Smith, 1842, it was laid down, "the public use and exercise of an invention means a use and exercise in public, not by the public, and it is of no importance whether an invention has been used by one or used by five." Stead *v.* Williams, 1843.

As regards the last paragraph of "J. H.'s" letter, nothing that he states is relevant to the issue. It is of no consequence what was done by the persons after they had seen the model, as long as they establish the fact of having seen it.

As regards "J. H.'s" remarks in the fifth paragraph, that is so obviously true that it needs no comment; the case "J. H." has described stands in quite a different category.

To put the case in a hypothetical manner, A invents a machine and makes a full size working model of it, and then invites B, C, and D to inspect it with a view of purchasing the invention. B, C, and D decline to purchase. After B, C, and D have seen the full-size working model, A applies for a patent.

Now, applying the cases before quoted, B, C, and D are representative of the public, and if they were shown the invention that will be sufficient publication to invalidate the patent. A has no power to gauge B, C, and D's mental appreciation of his invention, and cannot do so. This is strictly "J. H.'s" case, and all other matters he mentions in his fourth paragraph are beside the point, and do not apply to the method of publication he sets forth.

I have not put forward my own opinion; that is of no value in such a case as this. Patent law is to a very large extent case law, and, apart from a knowledge of this consideration of "J. H.'s" facts, would be valueless. M. W. LLEWELLIN, C.E., F.S.P.A.

15, King-square, Bristol.

LIME KILNS AND LIME BURNING.

SIR, With reference to "J. F. S's." question in last Saturday's ENGINEER, I should like to say that a definite statement as to what is the best form of construction for a lime kiln cannot be made without some further particulars regarding the surrounding circumstances.

Assuming other conditions of the problem to be suitable, then the tower kiln is undoubedly preferable to any other, because its operation is continuous and the waste heat is utilised more completely than in any other form of kiln.

One ton of fuel to four tons of lime is a first-class result in ordinary tower kilns with solid fuel. I am interested in a kiln which is fired by producer gas, and eight tons of lime are being produced by one ton of fuel, and the lime is of much better quality than before the conversion of the kilns, because the fuel is not mixed with the lime at all, but is gasified outside the kiln in a gas producer. There is consequently no clinker, far less sulphur and, altogether a better product from the same stone. For metallurgical purposes the absence of sulphur is a great advantage, and it has been found that the lime will carry more sand when used for building purposes. Another great advantage is that no smoke is made by the kilns, because the fuel is properly burnt and the whole of it is utilised, whereas in the ordinary system of solid firing all the gaseous constituents of the fuel are driven off in the form of smoke before the fuel becomes hot enough to burn. About 35 per cent. of the weight of the fuel is thus wasted. If the fuel happens to be of poor quality a great deal of ash and clinker is carried down with the lime, and this has to be picked out when the lime is drawn. In the gas-fired kiln the whole of the ash and clinker remain in the producer, and are drawn by the fireman about once in twenty-four hours. Besides all this the labour entailed in charging the fuel is much less than with solid fuel put in at the top of the kiln. W. J. JENKINS.

340, Queen's-road, Cheetham, Manchester,
March 9th.

MILITARY HORSELESS CARRIAGES.

SIR,—Referring to your article in last week's ENGINEER *re* "Military Horseless Carriages," you make some remarks on Boydell's wheels being used on ploughing engines, and crossing ploughed fields with the utmost ease. That is no exaggeration; I remember my father nearly thirty-five years ago using a traction engine—by Burrell, of Thetford—for haulage purposes, only fitted with the wheels in question. There was no difficulty in the engine travelling on bad roads and soft ground, but having to run in its daily work on the hard roads, the shoes, as we called them, soon got out of repair, and after several months' running had to be discarded for smooth wheels, but after doing that, it necessitated the laying down of a narrow gauge tramway alongside the bad roads, and across the fields where the said engine could travel when fitted with Boydell's wheels.

I quite agree with you that similar wheels would enable an engine to cross the sand of the desert. The principal thing to provide against is wear and tear, which I think could very easily be done with the present experience and materials. W. COOPER.

Dublin, 9th March.

JAMES WATT AND CO., SOHO WORKS.

SIR,—The letter of your correspondent, "One of the Staff," is evidently that of a disappointed man. The fact remains that under the management of "a large and expensive office and staff with the proprietor at the head," this great business came to grief. Can it then be wondered at that the present proprietors, who are successful men of business, should exercise their discretion in the selection of the assistants they thought proper to retain?

March 9th. SOHO.

COAL PREMIUMS.

SIR,—Since my arrival in England this time I have endeavoured to steer clear of controversial questions as regards railway matters. In the first place, I have no leisure for controversy; and, secondly, experience teaches me that the discussion of such subjects is apt to arouse a spirit of virulent partisanship, which I am unable to understand and with which I have no sympathy whatever.

I feel, nevertheless, that it would be ungracious not to respond to the very courteous appeal so pointedly made to me by Mr. C. E. Stretton in your journal. I therefore desire to say that I myself am not in favour of the coal premium system.

CHARLES ROUS-MARTEN.

26, Chelsham-road, S.W.

SIR,—I am, I think, in a better position to answer Mr. Stretton's question than Mr. Rous-Marten can be. I assume that Mr. Stretton really asks for information, and does not wish to air drivers' grievances. This being so, I can assure him that the coal premium system effects such a saving that railway directors are not likely to abandon it. The drivers have as much coal as they ask for. If their trains are late, they are fined. The best drivers like it; the incompetent do not. These are the facts in a nutshell.

March 11th. A RUNNING SHED FOREMAN.

RAILWAY COACHES.

SIR,—Being much interested in the building and maintenance of railway coaches, I have long been anxious to obtain information of a sound and authentic character on the following questions, and perhaps some of your readers will be generous enough to enlighten me and your readers generally (1) as to the difference in time which an underframe of a coach will last, without and with the vacuum brake; (2) and what effect, if any, has the vacuum brake upon the bearings or brasses of a coach?

I would suggest that it would be more satisfactory, and of more practical value, if this information could be supplied as regards the actual mileage worked, rather than by a time measure.

March 10th. HEADSTOCK.

BRITISH WARSHIP BUILDING NOTES.

IN view of the new orders for battleships, cruisers, &c., which may shortly be expected to be distributed among the Royal Dockyards and private shipbuilding and marine engineering establishments, the following notes of the progress made with some of the unfinished battleships and cruisers ordered under the late Spencer programme may be of interest at this time.

Of the battleships nearest completion the first to be noticed is the Renown, an armoured steel vessel of 12,350 tons displacement, which was built at Pembroke and launched last May, and has been engined by Messrs. Maudslay, Sons, and Field, of Lambeth. The progress made—after her launch—in fitting the machinery was so rapid that she was enabled to leave Pembroke for Devonport on November 14th under her own steam. The Renown is the only ship of her design yet constructed, and it is noteworthy that the new battleships to be built under what we may now, we presume, call the Goschen programme, are all to be of the Renown type, but with some increase in displacement and armament. It is also worth noting that the time taken—six months only—in fitting the engines and boilers on board the Renown in Pembroke, where very poor facilities for such work exists, was appreciably less than in the case of the Magnificent at Chatham, and the Majestic at Portsmouth.

The next battleship in order of completion is the Prince George, an armoured steel vessel of 14,900 tons displacement, built at Portsmouth, and engined by Messrs. Humphrys, Tennant, and Co., of Deptford. The whole of this vessel's machinery, boilers, &c., is in place, but the work upon the ship has been very fitful in its progress; it is, however, so far advanced that she will be ready for steaming at moorings in May, for her official trials in July, and it is hoped she will be completed in October.

Rapid progress is being made with the new battleship Victorious, lately launched at Chatham Dockyard, and described in our columns, large numbers of workmen of all trades being employed upon her, many of them working overtime. About seven-tenths of the whole weight of the structure, including armour, has been built into her, but the casemates are rather backward, due to their armour not being delivered fast enough from the contractors.

The builders of the engines—Messrs. Hawthorn, Leslie, and Co., of Newcastle—are employing a large staff, working overtime, to get the machinery fixed in the ship as soon as possible. The main engines and boilers are now in place, and in a forward state, and the fixing of the auxiliary machinery—which includes about eighty sets of engines—is being rapidly proceeded with. The armament is being fitted in place, and the hydraulic machinery for working the 12in. breech-loading guns to be carried in the barbettes is also being steadily advanced. Every exertion is being made to have a trial of the machinery of the ship in the dockyard basin in June, and it is expected that the vessel will be able to proceed to sea for her official steam trials in July, and be finally completed next October.

The first-class cruiser Powerful, building by the Naval Construction and Armaments Company at Barrow, is rapidly approaching completion, the whole of the structure of the hull and steel work in her being finished, and the armour of the barbettes, casemates, and conning towers, in place. All decks are laid, bridges and deck houses up, masts and fighting tops stepped, and the rigging practically complete. The steering, windlass, capstan, and hoisting engines and gear, with the anchor gear and air compressing machinery, are all in place and complete. The magazines, shell and store-rooms are lined and fitted, and rapid progress is being made with the ventilating systems, electric light installations, telegraphs, &c.

The main engines and all the boilers — which are of the Belleville water-tube type — thirty in number, are now in place, leaving only the armour gratings and casings over the boiler-rooms to be closed and finished, and it is expected to have steam up in a couple of months.

The Terrible—sister ship to the Powerful—building by Messrs. J. and G. Thomson, of Clydebank, is making very fair progress towards completion, but in consequence of the late strike in the Clyde district, and the engineers having only lately resumed work, the construction of the ship has been much retarded. As, however, the contract date for her delivery is January, 1897, this will no doubt easily be anticipated by her builders.

The work of completing and getting ready for sea the new second-class protected cruiser Minerva, whose float out at Chatham Dockyard was recorded by us last September, is being pushed along at a truly marvellous rate. This vessel, it will be remembered, is being supplied with her propelling machinery by the engineering department of Chatham Dockyard, and it being desired that her steam trials may take place in May, and her final completion be effected in July, a very large number of all classes of workmen is employed upon her with this object. The material now worked into her weighs nearly 2400 tons, including armour; the fixing of her machinery is far advanced, the work of fitting her armament on board is well forward, and her torpedo tubes are nearly complete. This vessel has a coal capacity of 550 tons, and her engines, which are of the three-cylinder inverted triple expansion type, driving twin screws, are expected to develope 9600 indicated horse-power under forced draught to her boilers, and to give her a speed with that power of 17¼ knots.

The progress of construction of the armoured battleship Illustrious, now building at Chatham, is very much behind, when compared with the celerity shown in the building of her sister ship, the Magnificent, at the same yard. The first-named vessel was laid down just a year ago, but is as yet only plated up to the armour deck, some only of the frames of the superstructure above that deck being in place. The boiler bearers and part of the auxiliary engine bearers are also in place, but the outer brackets for carrying the stern shafts will not be ready for a month.

The propelling machinery of this vessel has long since been completed by the engineer contractors—Messrs. John Penn and Sons, of Greenwich—and is waiting for transmission to the ship. It will be some considerable time before the vessel can take the water, unless a greater number of hands than is now employed is started to work upon her.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

J. M. T. (Cardiff).—*Your feed pump will pump boiling hot water if you will raise the tank from which it draws so high that the pump barrel will fill without any suction action. Probably a head of 5ft. on the suction side will suffice.*

W. L.—*We believe that it has been stated that a steam turbine has been run up to 60,000 revolutions, but we are unable to say whether it is true or not. We are inclined to think not. Professor Unwin has registered a speed of about 31,000 per min. with a special steam turbine.*

R. H. (Heaton).—*There is no special treatise on the care and construction of the marine boiler that would be likely to suit you. If you will state on what point you want information we will endeavour to supply what you want. The subject has been dealt with in almost every treatise on the marine engine and boiler, but not, we suppose, in the way you want.*

MACHINES FOR PAINTING MOULDINGS.

(*To the Editor of The Engineer.*)

Sir,—I shall be obliged if any of your readers can give me the address of a firm that make a special machine for painting mouldings up to 6in. wide with rotary brushes.

S. A.

Bradford, March 3rd.

DRYING APPARATUS FOR ORES, CLAY, AND PHOSPHATES.

(*To the Editor of The Engineer.*)

Sir,—May we ask the names of makers of driers for roasting ores, phosphates, clay for bricks, Portland cement, towns refuse, and articles which are to be baked.

J. H.

Manchester, March 6th.

SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. £0 14s. 6d.
Yearly (including two double numbers) .. .. £1 9s. 0d.

If credit occur, an extra charge of two shillings and sixpence per annum will be made. The Engineer *is registered for transmission abroad.*

A complete set of The Engineer *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
Half-yearly .. .. £0 18s. 0d.
Yearly .. .. £1 16s. 0d.

Thick Paper Copies—
Half-yearly .. .. £1 0s. 3d.
Yearly .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of The Engineer.

MEETINGS NEXT WEEK.

The Institution of Civil Engineers.—Tuesday, March 17th, at 8 p.m. Papers: "The Lixiviation of Silver Ores," by Mr. John H. Clemes, Assoc. M. Inst. C.E. "Mining and Treatment of Copper Ore at Tharsis, Spain," by Mr. C. F. Courtney, M. Inst. C.E. "Tin Smelting at Pulo Brani, Singapore," by Messrs. John McKillop and T. Flower-Ellis. Thursday, March 19th, at 2.30 p.m. Students' visit to inspect the Thames Ironworks, Orchard Yard, Blackwall.

The Institution of Junior Engineers.—Saturday, March 21st, at 3 p.m. Visit the electricity works of the Parish of St. Pancras.

Royal Institution of Great Britain.—Tuesday, March 17th, at 3 p.m. Lecture: "The External Covering of Plants and Animals: Its Structure and Functions," by Professor Charles Stewart, M.R.C.S., F.L.S. Thursday, March 19th, at 3 p.m. Lecture: "Masters of Modern Thought—III. Goethe," by the Rev. William Barry, D.D. Friday, March 20th, at 9 p.m. Discourse: "Immunisation against Serpents' Venom, and the Treatment of Snake-bite with Antivenene," by Professor T. R. Fraser, M.A., LL.D., F.R.S. Saturday, March 21st, at 3 p.m. Lecture: "Light," by the Right Hon. Lord Rayleigh, M.A., D.C.L., LL.D., F.R.S., M.R.I., Professor of Natural Philosophy, R.I.

Royal Meteorological Society.—Wednesday, March 18th, at 7.30 p.m. Lecture: "Weather Forecasts and Storm Warnings, how they are Prepared and made Known," by Mr. Frederic Gaster, F.R. Met. Soc. Illustrated by instruments, diagrams, and lantern slides.

Society of Arts.—Wednesday, March 18th, at 8 p.m. Paper: "The Bahamas Sisal Industry," by Dr. D. Morris, C.M.G., M.A. General Sir Henry W. Norman, G.C.B., G.C.M.G., will preside. Thursday, March 10th, at 8.30 p.m., at the Imperial Institute, South Kensington. Indian Section. Paper: "The Great Landslip at Gohna, in Gurhwal, and the Measures adopted to prevent Serious Loss of Life," by J. H. Glass, C.I.E., Chief Engineer, Dept. Public Works, Bengal. Sir Charles H. T. Crosthwaite, K.C.S.I., Member of the Council of India, and late Lieutenant-Governor of the North-Western Provinces and Oudh, will preside.

DEATHS.

On the 8th inst., from pneumonia, at his residence, Whiteness, Broadstairs, James Abernethy, Esq., J.P., Past President Inst. C.E., F.R.S.E., aged 81.

On the 6th inst., W. H. Le Fevre, Esq., C.E., of 26, Budge-row, Cannon-street, and 48, Argyll-road, Kensington.

THE ENGINEER.

MARCH 13, 1896.

TRIPLE CYLINDER LOCOMOTIVES.

The number of compound locomotives in the world is augmenting. The augmentation is, it is true, confined almost exclusively to the United States. It may, we think, be taken as proved that under suitable conditions a considerable saving of fuel may be effected by compounding. These conditions are, first, that the engine shall be fully loaded; and secondly, that it shall run for long distances without stopping. When comparisons are made in the United States between the compound and the simple engine, it is almost invariably the case that the latter is worked to a disadvantage. We have only to consider the enormous quantity of coal burned per mile in the United States to see that this must be so. There is little or no expansion. The engines are pushed to the last degree. The compound engine has far more cylinder capacity for a given power than the simple engine, consequently instead of exhausting at pressures of 70 lb. or 80 lb. on the square inch, the compound engine exhausts at 30 lb. or 40 lb., and so much more work is got out of the steam. But all advantages of this kind may be neutralised if the engine is not fully loaded, because then, by a well-known law, cylinder condensation is greatly increased, and the proportion which the back pressure bears to the effective pressure rises, with the result that no benefit is obtained. This is no doubt the reason why so little progress has been made in this country with the compound locomotive. On the whole our engines draw much lighter loads than those hauled in the United States. The conditions of traffic are different. They suit the non-compound engine admirably, and they have not suited the compound locomotive hitherto. It remains to be seen, however, whether changes will not have to be made in the conduct of traffic which will re-open the whole question, and in a manner force the compound system into use. The growing tendency to run trains over long distances at high speeds is slowly, almost insensibly, introducing modifications in the design of express locomotives. We have evidence of this in the Caledonian engines built by Mr. McIntosh, the first of which we illustrated last week. The fine engines built by Mr. Dean for the fast traffic of the Great Western system furnish another example. The new engines designed by Mr. Harry Pollit for the London service of the Manchester, Sheffield, and Lincolnshire Railway are different, as our readers will see next week, in several respects from their predecessors. Locomotives of greater and greater power are now turned out. The paramount difficulty lies in augmenting the steaming capacity of the boiler, without wasting coal, while coupled wheels are retained. With single drivers we may have as long a grate as a man can fire; but coupling is indispensable when very heavy trains have to be run in all weathers with certainty, and the length of the grate is limited by the space between the driving axles. It is worth while to consider whether a new departure may not be necessary. The compound system ought to work to advantage when a train of 200 tons has to be hauled at an average speed of sixty miles an hour, let us say, from London to Aberdeen, with runs of 150 miles or so without a stop. Even an increase of 10 per cent. in the efficiency of the machine would be worth having; not because of the pecuniary value of the coal saved, but because it represents 10 per cent. more work to be got out of the engine. But besides this we think we shall be able to show before we have done, that by using three cylinders instead of two, we may secure very important advantages in design, quite apart from compounding, while the conditions are such that if three cylinders are to be used, it is just as easy to work compound as simple. In a word, by using three cylinders in the way we are about to describe, an engine of greater capacity than anything hitherto built in this country may be produced.

We take, then, as a basis Webb's system, and this we do because it permits the use of four driving wheels, and yet dispenses with the coupling rods. Consequently a very long grate may be used. The wheel base between the drivers will also be long, but as the curves are all fairly easy on our great main lines, this is not an objection. But the Webb engine has probably reached its maximum dimensions. A 32in. cylinder is the largest it is possible to put between the frames, and that is, in the opinion of many competent authorities, too large to be suitable for a locomotive. It is, however, clear that the power of an engine is limited by the dimensions of this cylinder. Let us take, for the purpose of comparison, a Webb engine with two 14in. outside cylinders and one 30in. inside cylinder. The areas of the pistons are $154 + 154 + 707 = 1015$ square inches. If, now, we reverse the whole arrangement and put one high-pressure cylinder, 23in. in diameter, between the frames, and two low-pressure cylinders of the same diameter outside the frames, we then have $415{\cdot}5 + 415{\cdot}5 + 415{\cdot}0 = 1245$ square inches of piston area; that is to say, an engine over 25 per cent. more powerful than Mr. Webb's heaviest engine. It is true that larger high-pressure cylinders might be used in a Webb engine, but only by altering the proportions between the cylinders for the worse, and in the same way a larger single high-pressure cylinder might be used if necessary. The weight on each pair of drivers would be about 19 tons, and with 14 tons on the leading bogie, the total would be 50 tons. It is possible that weight might be saved if it were deemed desirable, but this is a detail. The driving wheels must be 7ft. in diameter; we do not think it would be necessary to use anything larger, but a diameter of 7ft. 6in. is available if preferred. The general lines of construction could be very similar to Mr. Webb's Marchioness of Stafford, except that the leading end would be carried on a bogie. We have here an engine with three cylinders, all of reasonable dimensions, and in many respects identical, a matter of some importance as affecting construction.

The first objection that will be urged is that the stress which the 160 lb. steam would exert on the central crank would be more than it could bear. It must not be forgotten that this stress would only be possible at starting, because when running there is always the back or receiver pressure in the high-pressure cylinder, tending to relieve the stress on the crank shaft, and the wheels would certainly slip to begin; but there would be not the least difficulty in providing a couple of fore-and-aft bearings on the central axle to give it support, identical with those used with perfect success in the broad gauge engines of the Great Western class. The single bearing was put between the cranks, and carried no weight worth mentioning; although in most cases a spring was used, carrying perhaps a ton, to hold the bearing down and keep it steady. A little scheming would be needed, but nothing to puzzle a draughtsman accustomed to locomotive work. It goes without saying that all the main bearings must be very long, just as they are in all Mr. Webb's engines.

Mr. McIntosh has shown that it is possible to get a very large boiler on to the narrow gauge. But the true measure of boiler power is, after all, the grate surface. If we take 3ft. as the maximum effective width of grate—because there ought to be always a dead bar at each side—we see that to get 21 square feet we must have a grate 7ft. long. The trailing axle may come up close to the fire-box behind, but the leading crank axle centre cannot well come closer than two feet, and so we drift by degrees into a wheel base of about 11ft. for a 7ft. grate. But a distinct advantage would be gained by pushing a little further the step grate principle adopted in some foreign locomotives with success. The back of the fire-box would be shallower than the front, and the grate bars would be at two levels with a nearly vertical portion uniting them. In this way the grate area would be augmented, and as the back part of the grate would be over the trailing axle, a wheel base less than 11ft. might be had. The centre of the boiler would in any case be high, but not higher—nor, indeed, as high—as that of some very successful fast American locomotives. The valve gear would present no more difficulties than are now successfully overcome. The diameter of the boiler must be considerable, probably nearly 5ft. and 1600 square feet of heating surface could be got in without unduly augmenting the length of the tubes. The major portion of the fire-box must have straight sides, a large tube plate being got by dishing out the front edges of the side plates in the way practised with success by the late Mr. Stroudley on the Brighton line. The tractive effort of such an engine as we have sketched would be enormous; and there is absolutely nothing in the design to prevent a very high speed from being attained. The maximum average turning effort of the high-pressure cylinder would be about equal to that of the two low-pressure cylinders, or, say, at the rail, 151 lb. per pound of effective pressure. This load of 19 tons would hold with a little aid in bad weather at starting from the sand blast.

Objection may be taken to an engine such as we have sketched. Indeed, it may be taken to any design; but if it is once admitted that an extremely powerful high-speed locomotive is wanted, it will, we think, be conceded that the way out of the difficulty which we propose is reasonable. On no other lines can the same amount of cylinder capacity be got, at the same time that enough adhesion is available to utilise that capacity. It is of no use to add to the diameter of a cylinder unless we provide adequate adhesion. We cannot get this by coupling, because we shorten the grate too much, or we are driven to use coupling rods dangerously long. In the United States a partial solution of the problem is found in raising the grates above the tops of the trailing drivers, but the scheme does not commend itself to English engineers. Mr. Webb's engines have been so successful that there is every reason to think that a locomotive such as we suggest would give satisfaction.

If the time should arrive—and it may be nearer than is thought—when a locomotive with 21in. cylinders, 26in. stroke, is required to conduct fast traffic, it will severely tax the resources of engineers to provide a boiler big enough to supply steam to such cylinders. On the Great Northern there are engines running with 19in. cylinders, 28in. stroke. Their capacity is, the driving wheels being 8ft. in diameter, very nearly 3865 cubic feet per mile. A pair of 21in. cylinders with 7ft. wheels would have a capacity of 5370 cubic feet per mile. If 1200 square feet of heating surface suffices to supply on the Great Northern 3865 cubic feet of steam per mile, then a boiler with 21in. cylinders must at the same rate have about 1700 square feet, while if a grate of 18 square feet is just right for 1200ft. of heating surface, 25·5 square feet is just right for 1700 square feet. No load can be placed on one pair of drivers competent to supply enough adhesion for a pair of 21in. cylinders. Consequently, coupling is essential, and the coupling must be at the fire-box end, because the cylinders must be outside, and we cannot couple at the leading end. Save in the way we have indicated, it seems to be impossible to provide the proper grate area, while retaining a design which, in its general features, will commend itself to English railway men.

THE ELEMENTS OF SUCCESS IN ENGINEERING AS A PROFESSION.

IN a brace of articles we have lately dealt with what we conceive to be certain elements of success. We have shown, or attempted to show, that to do a thing well is, as a rule, more paying than to do it badly or indifferently, and that, too, notwithstanding the fact that the demand does not always insist on a high standard of quality. We have also indicated that the road to success seems to us—and we believe that on this point most persons will be ready to assent—to be the highway of specialisation. We wish now to take a retrograde pace and get back to the very starting line whence runs the race for pecuniary and honourable emoluments. And this we are constrained to do from an anxiety not to raise the hopes of the younger community by making the road to fortune seem too easy and flowery. We have said that the route *viâ* specialisation is "not wholly unadorned by the *primula vulgaris*," and that it is a sure road to those who are able to set their feet in it; but we have not, we are glad to remember, forgotten to remind would-be travellers of the necessity of thick soles to their shoes; we ought at the same time to have warned the younger pilgrims that no matter on what path to success they wish to tread, certain qualifications are of vast importance. To be well shod and well knapsacked is by no means sufficient. To be supported by a good stout staff of personal or allied influence—and we do not for a moment underrate its importance—is helpful, but still not enough. It lies in a man's thews and sinews to win races, and no matter howsoever well he may be accoutred, be he knock-kneed or bandy-legged, flabbly-fleshed, or two thick or too thin or short-winded, others will be in before him.

Now, to put metaphor aside, we wish to call attention to the fact, not sufficiently grasped by very many persons, that engineering is not a profession which everyone may take up with certainty of success. There are professions, we believe, in which, with application, even the most deplorably inapt student of engineering might find distinction. The dean of a well-known London college once in an opening-day speech said that while there were doubtless some students present who would in the future be known as men of mark in the engineering world, there were doubtless others who, impelled by the ruthless hand of fate or ill-fortune, would end their days in the Houses of Parliament. He certainly knew from experience that year after year there were enrolled on the college lists names which would in the future be unknown and unhonoured in scientific circles, some too, the names of youths, who had they been more wise in the selection of professions, might have gained no little success. There is, unfortunately, a tendency among parents to consider that if a child in the nursery shows any marked propensity towards the conversion of furniture and firewood into one knows not what of marvellous machines, he is naturally predestined to be an engineer. A fatal error. As well expect every boy who plays with tin soldiers to become a general, as every child who essays to convert his father's umbrella into a flying machine to develope into a mechanical genius. It would seem quite unnecessary to insist on a point so evident. Still the most evident truths are those most often ignored.

But to carry the matter a step further towards the point on which we wish to insist. Suppose a youth really does exhibit mechanical genius, and is sent to school and college, and acquires as much as his masters are paid for or are able to teach him. Suppose, moreover, that he is backed up by a fair amount of influence, is it wise—it is a thing so often done—to prophecy his success? Undoubtedly not. Success, by which we mean pecuniary success, depends more upon a man himself than upon his genius. That is to say, there are characteristics far outside the particular feature in which any one man may be a proficient which are essential to his progress. A very capable mechanician, for example, might be so hopelessly lax or incompetent as a man of business that he would be continually hampering his own prospects. Everyone can call to mind cases which display this and the converse, only the converse is very much more rare, for a capable merchant with a smattering of science will make a fortune, when a proficient scientist, having a fair acquaintance with commercial matters will starve.

We have said at other times, in writing of the education of engineers, that a careful study of the aptitude and character of a youth should be made before he is embarked on a profession which to an incapable man is, perhaps beyond all others, disastrous. Engineering in this country is separated from other professions by insisting on no definite standard of excellence. An engineer is at perfect liberty to practice without holding any diploma. This freedom has advantages and disadvantages. On the whole, the disadvantages seem to preponderate, and though we confess to but a small belief in the value of examinations, we should like to see one of our great institutions become constituted a board of examination for engineers. The benefit would lie in the weeding-out virtue possessed by the implied education. Men who had not the sufficient courage and persistence and love of their work to live down repeated failures would give it up and try some other profession, while others who foresaw the difficulties would be deterred from attempting them if they were not very much in earnest. We do not know, however, if it is possible to design a form of examination which can be relied on as foretelling the future of the examined. We fancy not. There are points of very vital consequence to success which are undiscoverable by question and answer—the determination, perseverance, energy, the common sense and tact which are the principal ingredients of the eminently prosperous man. If a man knew all that was to be known about some particular subject, and was entirely devoid of these attributes, his chances of distinction, nay, of even comparative success, would be few. But give a man these, and but poor talents or abilities to begin on, and he may prosper in spite of the drawbacks. The number of persons who combine these necessary qualifications is comparatively small. But in a suitable combination of men they may all be found. Companies are, as a rule, floated, and partnerships joined, for capital's sake. Here, however, is another very good reason for the co-operation of two or three men, and we may say with certainty that herein is an element of success, that each by bringing certain particular qualifications not possessed by the others, and dovetailing his particular talents in with theirs, produces a composite whole equivalent to one entirely competent person.

After all, we are still on the same road—it is still specialisation, only now specialisation of intellect in a limited circle, whereas before we spoke of the specialisation of production. How far such co-operation of specialised intellect may be carried with success it is not easy to say. To a certain limited extent it is now practised with excellent results, the most patent case being, of course, the partnership of a technical with a commercial man, but it probably is capable of much further development. The one technical man may, of course, be replaced by several, each being devoted to a small section of the entire concern. This is done as a rule in very large establishments, and undoubtedly contributes to their success. In smaller places, however, it is usual for the proprietor or manager to exert control over all departments. As the knowledge required is frequently very varied, it is, from our point of view, improbable that any one man will be sufficiently expert in all branches to bring each to perfection. His control should be more largely managerial, the directing when and where to do, but leaving the doing to persons with particular experience in different matters. We know perfectly well the difficulties in the way of carrying out such a scheme to the extent we mean. A strong hand, however, overcomes all difficulties. An examination of the most prosperous establishments will show that they have been formed, as a rule, by one master, having drawn around him the talents which he lacked himself, and directed them into the channels where he saw they were needed. It has been said that there is a groove provided for every man, and if he can once get into his groove success is sure. It is part of the work of a master to get all of his subordinates into their right grooves. The groove is a specialised line. Some grooves must, of course, be narrow, but where all the grooves converge and join there is a broad and magnificent highway.

May we conclude with a word of advice to the coming engineer? Find out as early in your day as you can the groove in which you are predestined to roll, get into and let nothing put you out of it. Grooviness does not necessarily mean narrowness. The groove is small at the beginning, but it gets deeper and wider as the intellect which rolls along it increases in size. Remember, however, that success is more due to the character of a man than to his genius. Genius is a servant; character its master.

SCOTCH RAILWAY WORKING.

THE results of the working of the Scotch railways for the last half-year are even better than those of the English lines, for two reasons. One is that they compare with the period of a strike in the corresponding six months; and the other is that there is the inclusion of the returns for a mild January—for the Scotch period terminates later than the English half-year; and the results are shown by the Glasgow and South-Western line. It paid £15,000 less for coal for locomotive power in the last six months than the preceding corresponding period—which is a large reduction from payments that were £43,353. This is one of the main causes of the reduction in the percentage of working expenditure, which fell from the high rate of 59·48 per cent. in the strike period to 51·56 per cent. for the half-year just reported on. At the same time, the reduction thus stated has been materially aided by the increase in the gross receipts from £613,000 to £701,000 for the six months—an increase that was spread over nearly every item in the receipts. There was a moderate expenditure of capital, too, on new works—the total for the six months having been about £53,923, of which £12,252 were on "lines and works in course of construction," and nearly all the remainder on lines and works open for traffic, the largest items under the latter heading being £10,043 on the engine sheds, &c., at Carlisle; and of £3432 on the engine sheds, &c., on the Paisley Canal line. In the current half-year the estimated capital expenditure is rather larger, £84,976 in the total, the increase being general, but including a proportionate sum for new working stock. The other great railways in Scotland appear to have had the same benefits by contrast with the period of the strike which forced up the price of coal, whilst it also greatly reduced the mineral traffic. The recent working has seen coal at normal prices with larger coal traffic, and a consequential increase of the earnings of the companies, both gross and net. And there is now the advantage of coal under contracts that are even lower in price, whilst the traffic shows a tendency to increase, both in passenger and goods branches. On one of the lines—the Caledonian—there is a heavy expenditure, but it has now the accompaniment of some of the earlier works being brought into operation, so that concurrently with a large capital expenditure there is an increasing income. For the present there is the prospect before the Scotch railways of full traffic and of moderately low working charges.

AFRICAN LAKE AND RIVER TRANSPORT.

THERE has just been shipped from the Clyde, per s.s. Isle of Dursay, an interesting cargo destined for South-East Africa, and thence to the interior, which in all probability will mark important fresh developments in the commercial and industrial progress of Central Africa. This comprises three steamers and two steel barges—important additions to the already numerous fleet of lake and river steamers which the African Lakes Corporation, Limited, have plying on the rivers Zambesi and Shire, and Lakes Nyassa and Tanganyika. It also includes a powerful traction engine and several goods wagons, intended to develope transport by road past the Murchison cataracts on the Shire, thus connecting the river service at present conducted below and above the cataracts. The road traction engine has been adopted pending the construction of a railway alongside the cataracts, for which the Corporation are now making surveys. Two of the three steamers are stern wheelers of similar type and of very shallow draught. One named the Princess, 85ft. long and 13in. draught, is intended to augment the Corporation's flotilla of steamers now plying on the Zambesi and Lower Shire, between Chinde, the port where cargo is received from the ocean-going steamers, and Katungas, the port nearest the cataracts where navigation is at all practicable. The second stern wheeler is intended to ply from Matope — the nearest navigable point above the cataracts — to the mouth of Lake Nyassa, in supplement to the twin-screw steamer Livingstone, already running upon the Upper Shire. The third is a screw steamer, which has been named Queen Victoria, and is intended to run upon Lake Nyassa. She will be the largest and best equipped steamer on the lake, and will materially strengthen the service which the company already maintain upon that lake with the steamers Domira and Ilala, in connection with the service which they run on Lake Tanganyika by their steamer Good News. The new steamers, which have of course been constructed in sections, have been supplied by Clyde firms—one of the stern wheelers by Messrs. Russell and Co., of Port Glasgow, engined by Messrs. John Kincaird and Co., Greenock, and the others by Messrs. Ritchie, Graham, and Milne, of Whiteinch. With the extensive and well-organised connections already established, and especially with the fresh additions to their working facilities, the company will be in a position to deliver goods to all points on Lake Tanganyika, whether in British, German, or Congo Free State territory. Travellers also to the Congo State and other parts of the remote interior of Africa, will be able to reach their destination, *viâ* the Zambesi, with a degree of comfort and speed which a few years ago would have almost seemed impossible.

MACHINERY IN THE GLASS TRADE.

A DEPARTMENT in which machinery has not made as much headway as in some other spheres of industry is the glass trade. Manual labour is still employed to an overwhelming extent. The application of machinery to glass bottle manufacture has recently formed the subject of a correspondence between the Duke of Devonshire and a representative of the trade. Machinery was some little time ago used in England which purported to produce bottles at 3d. per gross as against 3s. 6d. by the hand blowing process, to make 80 gross a day with boys only, and to save 33 per cent. in men. It seems, however, that not a single glass-blowing machine is at the present time in operation in the United Kingdom. Information is, however, this week received, which shows that if the problem of introducing machinery in this department has been given up in England, an endeavour to solve it is being continued in America. Another machine has been invented there, and has been used with success, we are told, by the Toledo Glass Company, of Toledo, Ohio, which is now building a new factory for the mechanical manufacture of the finer grades of wine and beer bottles. The machinery grasps the molten glass as a blower would, and holds it straight while the mould closes. It then revolves the pipe. The mould next opens automatically, discharges the bottle, dips itself in water, and is ready for the next lot of glass. Working on tumblers, 400 have, it is stated, been produced in one hour, and electric bulbs have also been made. There is great scope in Europe for satisfactory glass-blowing machinery. One bottle works alone in Russia—that of Prince Vjazemsky, at Gorbunova, in Vladimir—puts upon the market 1,500,000 bottles per year, and advices from Germany state that the demand for bottles is extraordinarily large, the manufacturers being crowded with orders. Apparatus for holding and operating a bottle mould is not unknown, but it is the introduction of machinery for the blowing that is the innovation.

THE SHEFFIELD CANAL.

MUCH interest attaches to the development of water communication between Sheffield and South Yorkshire and the sea. The City of Steel has lost several of its heavy industries through lack of cheaper means of transit to the port. Rails, at one time a vast industry in Sheffield, are now made on a greatly reduced scale close to the place, to be delivered on railway sections in the Midland districts. The export rail trade is now exclusively done at the coast. Ship and boiler plates have also passed to other localities, and it has long been felt that unless the waterway to the Humber, the Trent, or the Ouse, can be vigorously developed, other heavy industries must follow rails, and ship and boiler plates. A company was formed—the Sheffield and South Yorkshire Navigation Company—to take over the canals of the Manchester, Sheffield, and Lincolnshire Railway. A year has just elapsed since the new company got to work, and the results of the improved facilities are already evident. At December 31st the company, as the aggregate of ten months' working, had carried 742,000 tons of goods, being an increase of 50,000 tons over the corresponding period of the previous year. The principal cargoes were iron, coal, grain, sugar, and timber. From March to December last over 500,000 tons of coal were conveyed over the canal. The company, with a view to further vigorous extensions, has purchased the Manor Yard and the tramway line from the Duke of Norfolk, and is making important additions to the storage accommodation, and the mechanical appliances required for the effective handling of heavy goods and large consignments of manufactures and produce of all kinds. Messrs. W. France and Co., shipowners, London and Goole, intend shortly to begin a regular service of steam barges between Sheffield and Goole. One or two of these steam barges have come through now and then, but a stated service will be a distinct advance in conveyance by the water-way.

LITERATURE.

Minerals, and how to Study them. By E. S. DANA. 8vo., pp. 380. New York: John Wiley and Sons. London: Chapman and Hall. 1895.

THE author of this interesting little volume tells us in his preface, that some hours which could not be devoted to more serious labour, have been occupied in preparing it, in the hope that it might encourage those who have a desire to learn about minerals, and increase the number of students with similar tastes. With this view the subject is presented in a simple and readable form, without too much detail, and at the same time without cheapening the science; while provision is made for those deficient in essential preliminary knowledge of physics and chemistry, by the introduction of a certain amount of elementary matter on these subjects. The compilation of a properly-balanced introductory text-book upon a large subject is not an easy task; neither is it facilitated by the possession of great detailed knowledge, except a proper judgment be exercised in selecting the matter to be presented. In this instance the selection has been exceedingly well made, and the product of the author's leisure—which we are afraid has been of an enforced kind and a consequence of the severe work involved in the preparation of the sixth edition of Dana's "System of Mineralogy," published in 1892—is a welcome and valuable addition to the stock of good elementary books. In form it is a short systematic treatise on the principal physical and chemical characteristics of minerals, particular attention being given to the simpler methods of identifying them by blow-pipe examination, approximate determination of specific gravity, &c., without going too much into details of exact form and structure, which require more elaborate and expensive methods of application than are at the command of beginners. The same principle has been followed in Chapter VII., which contains notices of about 150 typical minerals, and in addition to the ordinary details as to form, composition, and occurrence, describes telling peculiarities such as the experienced observer is accustomed to rely upon, but which as a general rule are not noticed for the benefit of beginners. Much attention has been given to the illustrations; as an addition to the ordinary geometrical projections of crystals, several of a more pictorial kind drawn from actual specimens are given. These are for the most part very good, the quartz crystal on page 15 and the weathered gypsum crystals on page 256 being specially successful. The frontispiece, representing a large, irregularly-developed crystal from North Carolina, although reproduced from a photograph, is not more satisfactory, and certainly tells less than the engraving noticed above.

Refrigerating and Ice-making Machinery: A Descriptive Treatise for the Use of Persons Employing Refrigerating and Ice-making Installations. By A. J. WALLIS-TAYLOR, A.M.I.C.E. London: Crosby Lockwood and Co. 1896.

THE increase in the literature of this subject is evidence of the growth of the industrial applications of ice and cold air. There is nothing new in Mr. Wallis-Taylor's book, but it is one of the best compilations on the subject, and the value of the work is very much increased by the numerous references which the author gives to the many scattered papers on the subject with which he deals in the proceedings of different institutions and in the pages of technical journals. The descriptions of the different refrigerating machines, and the principles on which they act, are described with an intelligent appreciation of the means and the end. In a great many cases the author's composition would be improved by a little careful editing, and certain of the engravings would have been better if they had not been so much of the style affected by some patent agents; but his book may be recommended as a useful description of the machinery, the processes, and of the facts, figures, and tabulated physics of its subject.

SHORT NOTICES.

Digest of British and Foreign Patent Laws. By Alfred J. Boult, M.I. Mech. E. London: Bemrose and Sons, Ld. 1895. 8vo. Price 5s. In 385 pages, this book gives a more or less extended account of the main features, not perhaps so much of the patent laws as of the law so far as it concerns the intending patentee and the patent agent. To both of these, however, it would have been more useful if the author had not so carefully refrained from giving the Government fees for each of the countries. He does give the yearly taxes in some cases, but not in all, and although these are of interest they are not of much use unless given for all countries, and never so important to the inventor as the various Government fees of first instance. The reason for omitting these is one which defeats its own object, and if a book has not its full possible use to inventors, it is not likely to have it to patent agents.

Mechanics for Beginners. By W. Gallatly, M.A. London: Macmillan and Co., Ld., 1896. Price 2s. 6d.—This little book, with its 253 pages, is no worse and no better than the score of treatises on mechanics which are now to be had. The examples for practice are many and well selected. The diagrams are satisfactory. The author troubles himself no more than other writers of similar books with the inconsistency of his definitions. This makes matters fairly easy for the normal student, who cares nothing and is not expected to care anything about the concepts of physics. What special end a mastery of the contents of the volume is supposed to serve we have no idea, but as an acquaintance with ergs and dynes and poundals is considered in some cases to be necessary, we fancy the student may as well avail himself of Mr. Gallatly's assistance as that of any one else.

Pleasure Cycling, with Hints to Riders. By F. T. Bidlake and Sennocke. London: Iliffe and Son, 3, St. Bride-street, E.C. Price 1s. This little book deals with cycling as a pleasure, and as a recreation of the highest character. It appeals to the wealthier classes, and is a pleasant talk upon various questions which interest the cyclist. It touches on the many points that will occur to those who are considering the advantages, disadvantages, pleasures of cycling, and pains and penalties of learning. Half at least of the little book will be found useful by many for these reasons, and some of the hints on road riding, care of a machine and dress, will interest others who are already riders. With regard to choosing a machine, and also with reference to "specialities recommended," it is a pity that these should form an exact index to the machines and the specialities advertised at the end of the book. It is true that the book has been published by Messrs. Iliffe and Son for the Coventry Machinists Company, but there is nothing to show this, and it is therefore of the nature of a trade circular appearing under the guise of a book by an independent author and publisher. It is prettily, though not usefully, illustrated, and cannot be compared in utility with the little book in the "Nutshell Series" published by the same firm.

BOOKS RECEIVED.

Sewerage and Sewage Disposal. By Henry Robinson, M.I.C.E. London: E. and F. N. Spon. 1896.

An Elementary Treatise on Rigid Dynamics. By W. J. Loudon, B.A. London: Macmillan and Co., Ld. 1896. Price 10s. 6d. net.

The Number Concept. Its Origin and Development. By Levi Leonard Conant, Ph.D. London: Macmillan and Co., Ld. 1896. Price 8s. 6d.

Electric Wiring, for the use of Architects, Underwriters, and the Owners of Buildings. By Russell Robb. London: Macmillan and Co., Ld. 1896. Price 10s.

JAMES ABERNETHY.

MR. JAMES ABERNETHY, Past President Inst. C.E., died on Sunday night, at his residence, Whiteness, Broadstairs, at the age of 81. In the death of Mr. James Abernethy we have lost another of a generation of engineers of high achievements, but whose ranks have been much thinned in the past few years. Mr. Abernethy's works were chiefly of harbours and docks, and of these he has left to himself great monuments. He acquired in his long life a great and well-deserved reputation for soundness of judgment in these matters, and was held in high esteem among his professional brethren. He had retired some years from active work, but occasionally gave opinions to within a recent time. He was some years since President of the Institution of Civil Engineers, and amongst other marks of public recognition, it will be remembered he was called in as one of the consulting engineers of the Manchester Ship Canal, and of the Ribble Improvement Works. We shall say something of his works in another impression.

SOME SPECIAL FEATURES SEEN IN BRITISH WORKSHOPS.

THE following article by Professor John E. Sweet, published in *Machinery*, is one of those which occasionally come from one American to the credit of all America:—

In response to your repeated solicitation to write of my observations while in English and Scotch machine shops, I comply with great hesitancy, because I can see no advantage in saying anything about what seems to be inferior to our own practice, and so far, whenever I have told of the things that seem to me worthy of praise, it has always led to a hot-water discussion, and many times the loss of friends. I certainly shall not deviate, however, from the first idea above expressed.

Although I was in Manchester a day, I failed to see any of the wonders there, because those of my acquaintances whom I remembered there were away, and as I had no letters, supposed that application to any of the workshops without would be useless. Later I found that the English readers of American mechanical papers were numerous enough to have made my name a passport to most of the places where I would have cared to go. This leads me to make another of the hot-water remarks, and it is this, that I think of all the civilised countries there is none where the mechanics know so little about what is done in other countries in the mechanical line as we do, and this comes from two causes—we think we are the leaders in all things mechanical, and hence it is not worth while to know what others are doing, and they also think we are the leaders, and that it is worth their while to know all about it. This in a sense is complimentary, and another thing to our credit is that it is easier for a stranger to see what is done here than in other countries.

At the works of John Lang and Son, at Johnstone, Scotland, they make it their business to build lathes, and one feature is that the bed is a box casting which goes to the floor, and when such a casting is a complete box, it is a good form in which to put the metal.

About all mechanics are beginning to believe that cast iron in a machine pays good interest on the cost, and there can be but one question as to which is the best form to put it, whether in a box section of the largest size possible, which is the stiffest form practicable, or in a plain square solid beam as suggested by Oberlin Smith, which embodies the anvil principle in its most complete form. The beam will sag by its own weight the most or as much as any form of any weight, and there is but one advantage, it may be the best to prevent chatter.

John Lang and Son have a quick change of feed to their lathes that they have been using for years, which we ought to have stolen long ago; I also found there the quick stop and reverse for radial drilling machines, which I had been advocating for several years, and finally had to make for myself, and was rather taken back to find not only that, but that worm gears for rotating the arm of radial drills are old and not uncommon. After two or three years' experience with the quick stop and reverse, I am of the opinion that it is quite as valuable an improvement on a drilling machine as the quick return, and in large radial machines a worm gear adjustment for the arm must be a consolation to the operator.

One thing that particularly attracted my attention about the Scotch lathes was that the workmen could not use a fine feed, nor did they appear to want to, for they seem to shift the lever from $\frac{1}{32}$in. to $\frac{1}{4}$in. feed, where they could without being told.

In the works of the South-Western Railway Company at Nine Elms, London, many things were seen that were new and a surprise. Whatever one tells about locomotive work, if he is not a locomotive engineer, is likely to be wrong, at least in the eyes of the locomotive engineer, and in this connection I have an apt story to tell:—

Their locomotive tenders are divided differently from ours. Our tenders are fixed for holding coal in the middle, and have the water tanks around the outside. In the case of the one I saw there at least, and I think common, the water is at the bottom and the coal on top, and the partition or floor between the two, high at the back, and about 1ft. above the foot-plate; the object being to have the coal naturally work forward and be easy for the fireman to handle the fuel. That appeared to me to be a good scheme. In mentioning the fact to an accomplished Western engineer, he said it would not do in this country at all. On asking why, he said:—"Because you could not carry half coal enough." This was the first time that I was dead sure I had too much mathematics for my own good.

The fire doors of English locomotives open like sliding doors, or two sliding doors in fact, so pivoted and linked that one handle opens both. This handle is convenient to both the fireman and engineer, so that in hard work the engineer can open and close the door for the fireman with his left hand, and without looking; with this advantage helping the stoker and helping the fire, as the door is kept open but a second. This sliding door cannot be blown open when a flue gives out. Whether there may not be some reason why this door would not work in America, I do not know. Thirty years before point switches were used here, they were universal in England, and a valid reason given why they would not work in our ice and snow, and yet point switches are common here now. Perhaps thirty years more will show that coal will slide down hill, and that sliding doors will stay shut the same in one country as another.

At the Nine Elm Works, where not only the repairs of the engines of the system are made, but the new locomotives as well, the assistant superintendent paid three or four of us Americans one of the highest compliments I ever received by spending at least four hours showing the most of what there was to be seen.

Locomotive boilers made tight without caulking, in fact a boiler shop where both drift pin and caulking tool were prohibited was a new thing to me, as was the whole boiler construction. Shell joints that gave 80 to 90 per cent. the strength of the sheet in place of 55 to 60, circular joints butted together and covered with a band shrunk on, and heads riveted to solid rolled angle hoops shrunk on with all holes drilled in place, seemed like a machine job rather than that of boiler work. As one of the engines that had just come in from its run was over thirty years old, it would seem that with the South-Western they found good work worth its cost.

It will likely take the British engineers as long to be convinced that the forged locomotive frame is better than the plate one, as it has our railroad men to be convinced that there was merit in the block system. The plate frame being such an easy thing to make, and filling apparently every requirement when it is made, gives a good deal besides prejudice to overcome before they will be convinced.

At the Nine Elm Works their facilities enabled them to pile ten plates top of each other with a template on top, follow around the template with a slotting machine, cutting the pile into shape, and without unpacking, run under three radial drills and drill all the holes without moving. In this way the frames for five locomotives are finished in a lot, and all alike within the allowable limit of error.

A milling machine carrying two mills 8in. or 10in. in diameter by about a foot long, slabbing two connecting-rods at a time, appeared to be a dozen years old, and a machine for grinding the slots in case-hardened links to the proper radius, and another one grinding the two end holes perfectly without revolving the links were as good pieces of devising as one can see anywhere.

First an emery wheel, mounted on a high-speed spindle, was caused to travel like a planet within the holes; so far, that was easy enough to do, but in addition, the wheel could be set out as the stock and wheel were ground away, and that while under motion as easily as an ordinary wheel is set up to its work, the wheel travelling back and forth to keep the holes parallel.

The English seem to make a distinction between forging done by machinery and that done by hand, the former being called "forging" and the latter "smithing." Special pride is taken in the amount and perfection of the forging, pieces of all shapes being smashed into shape ready for the milling machine without any hand work whatever.

Casting the two cylinders in one casting is the practice; a double boring machine used to bore both cylinders at once; and as the two valve chests are between the cylinders—the valve seats are not over 4¼in. apart—a special milling machine is made to stand on its head, go down between and dress the faces and ports. How often we hear it said, "This is the country where the milling machine was developed," and the impression conveyed that comparatively little is done in other countries. Such a conclusion can easily be reached if one will only go in the right shop here and the wrong shop abroad. On the other hand, the reverse conclusion would be reached if the searcher for facts should go into the works of Alfred Muir in England, and in the shops of Tom, Dick, and Harry here. I have been told by Americans that in no other shop in the world, not even in the Steinlen Works at Alsace, can such a variety of milling machine work be found as in Alfred Muir's works at Manchester. I give this second-hand, but have no reason to question its truth.

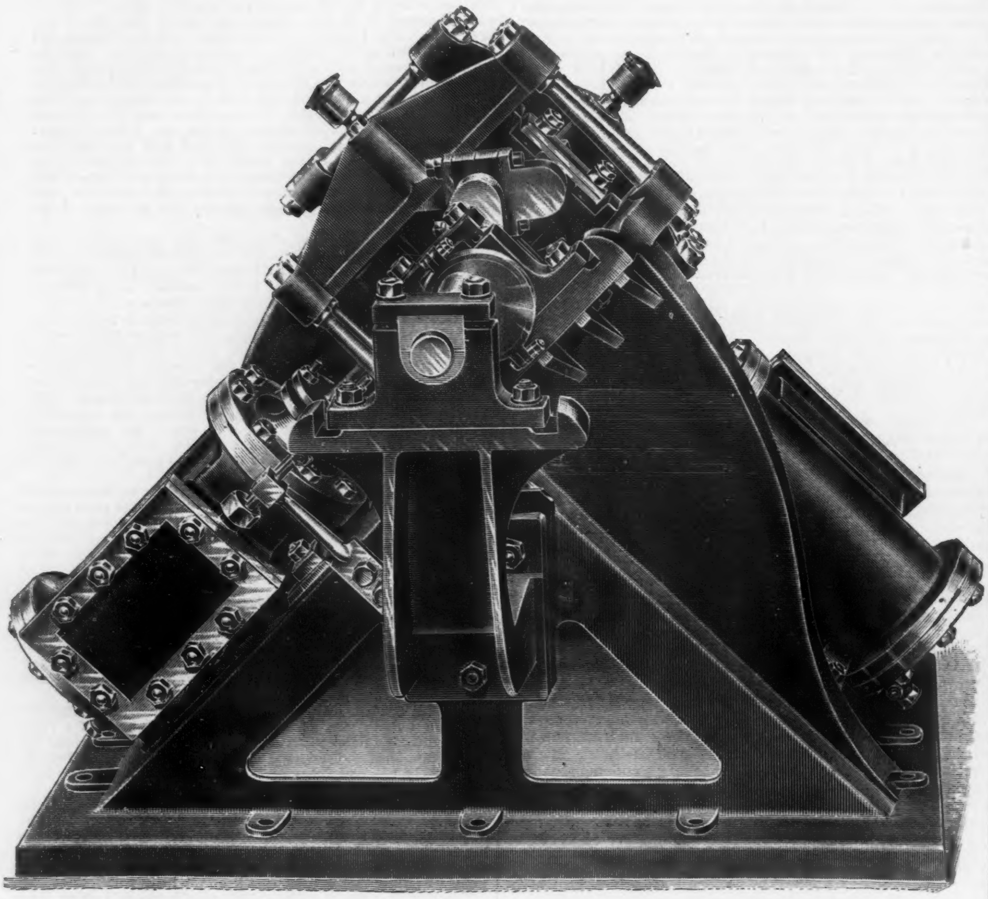
At the engine works of Willans and Robinson, Thames Ditton, two wonders await every American, except those who will not admit that anything can be done except what we do. There are a number of features about the engine that students in engineering have been taught to believe are contrary to the best practice, but experience shows that they produce the results, and the style of the engine renders good work necessary, and the good work produces results where it would be wasted on other designs.

The cylinders and steam chests are piled up one above another, and it is important that they be true and in line. These cylinders are bored, reamed and faced on an ordinary lathe, a regular English lathe, with no fixtures except a holder attached to the slide rest to carry the reamer, that is, the reamer is held and driven through the work by the slide rest and not by the tail stock. Mr. Eaton Shore—the works manager who, as well as every one connected with the company, gave me every attention, all information, and every opportunity possible to see and learn—is firmly of opinion, as I am now convinced, that the results obtained could not be continuously produced by the tail stock feed. As an example, a half-dozen cylinders some 14in. in diameter and 1ft. or so deep, with a flange outside at one end and inside at the other, were by the lathe just finished. One taken at random was sent to the testing floor and placed on an oiled surface plate. The testing plug, made like a web pulley, with about 2½in. face, was started in the cylinder and crowded down until about even at the top, when with a finger on the top at one side the plug was shown to be so free from contact with the sides of the cylinder as to spin around like a top. The man then stood upon the plug, and it carried his weight on the air. This job probably could be done in any good shop if one went at it the right way, but for one thing the castings are made from re-cast pigs, re-cast after the mixtures are made. This makes a uniform iron which is more likely to keep its shape, but is very hard, and that makes the work difficult. Such hard cylinders and the accuracy contributes to the success of the engine, but such accuracy would be of no particular advantage in an ordinary engine when the cylinders are distorted by steam in one place or on one side, and exhaust in another.

The Willans engine is, in its design, workmanship, and method of construction, so dependent one upon the other, that it is not easy to describe how things are done, and give them their due force, without describing the engine itself, and the whole would be more than a single article would cover, and I find that I must leave it. They have in use what I understand is a common thing, a flexible copper steam pipe, capable of resisting any required pressure, that bends around like a rubber hose. Not a double wire arrangement like Almond's, depending on mechanical fits, but an absolutely tight copper pipe constructed in such shape as to be easily bent around—an ideal device for an erecting floor.

It is useless to attempt a description of the interesting and wonderful things to be seen at the works of the Willans and Robinson Company, and to one who appreciates wonders some such thought as this must come to him—the death of a great engineer is a loss to the world. When Peter William Willans died, the world lost a genius.

CHAPMAN'S LINK MOVEMENT ENGINE



THE LINK MOVEMENT ENGINE.

We illustrate a curious engine patented by Mr. G. Chapman, and constructed by Messrs. John Milne and Sons, Milton House Works, Edinburgh. The object of the inventor has been to produce an exceedingly compact engine, and a glance at the engraving will show that he has accomplished his purpose. There are no connecting-rods. Roughly speaking, the two pistons move diagonally, and cross and recross midway at every stroke, a link, half the length of each, connecting them; a pin at each end of the link passing through the crossheads forms the respective cranks, and circular motions cause the rotation of the shafts, the pressure on the slippers being reduced to a minimum.

It is a known geometrical fact that any point in the circumference of a circle revolving on the inside of another of double the diameter will describe a straight line. Mr. Chapman's engine utilises this principle in a way that will be readily understood by the aid of the two small diagrams annexed.

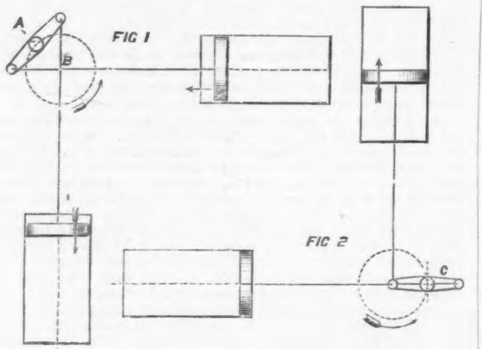


Fig. 1 shows the pistons at the ends of their strokes, and Fig. 2 shows one at half stroke. The crank length is from A to B, or half the diameter of the virtual circle within which the crank pins revolve. Any of our readers accustomed to geometrical work will see that this is an extremely pretty parallel motion without further description. The details of the engine have been very neatly worked out. It is not possible to dispense with guides, because the pressure on the pistons varies. But Messrs. Milne say that a new engine which they have tested gave about 78 per cent. of its indicated power on the brake at 180 revolutions per minute. This, for a small engine, with cylinders only 5in. diameter by 10in. stroke, is very good work.

The cranks are side by side, the flying crank C, Fig. 2, acting like an ordinary drag link. This seems to us to be a very meritorious attempt to solve a difficult problem.

COLLISIONS AT SEA.

A device for minimising the effects of collisions at sea has been described in an address delivered by His Excellency Admiral Makaroff, to the Hong Kong General Chamber of Commerce. He proposes that when a ship has been fitted with engines, boilers, water-tight doors, and everything else which cannot be damaged by water, a trial of the bulkheads should take place by filling the compartments with fresh water to the upper part of the bulkheads. This trial ought to be made in the presence of competent officials, who should certify that the bulkheads are strong enough to withstand the full pressure of water, and that they are water-tight.

Admiral Makaroff writes:—If the collision takes place upon one of the main bulkheads, two compartments are filled with water. In order to avoid this I propose that each main bulkhead should be supplied with extra small water-tight compartments at the side of the ship, from 10ft. to 12ft. wide. Then the collision would only affect one bulkhead of these small compartments, and the result would be that instead of two big compartments being filled with water only one big compartment and the little one would be flooded.

The general opinion is that the colliding blow is so very powerful that nothing can minimise the effect of it; but I can give proofs that even when the force of the blow is comparatively slight the skin of the ship is penetrated. It is a matter of fact that the vertical stem acts as a knife, and that very little energy is required to penetrate the skin of the ship which is run into.

In order to demonstrate the difference between touching the skin with a ram which is without a buffer and a ram with a buffer

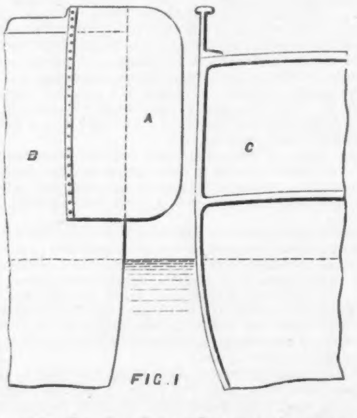

FIG. 1

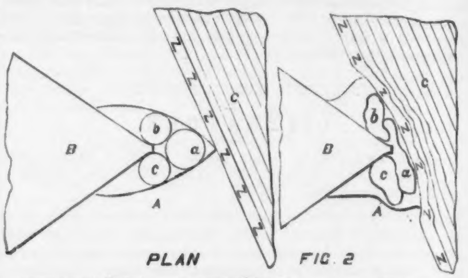
I made some experiments a few weeks ago on board my flagship Emperor Nicholai. Vice-Admiral Buller, Rear-Admiral Hoffmann, Commodore Boyes, and many captains were invited to witness them. A model representing a ramming vessel was moved by a weight so as to ram a model which represented the amidship section of a ship. A small buffer of $\frac{1}{4}$in. thickness of cotton cloth was made which could be adjusted to the ram. When the blow was dealt without the buffer the ram easily penetrated the skin of the other model and the ramming vessel made an inroad of $\frac{3}{4}$in., and cut a hole 2in. in length, which in reality means 8ft. When a similar experiment was made with the buffer on the ram an inroad of only $\frac{1}{4}$in. was sufficient to arrest the progress of the vessel, and the skin was only slightly bent and not penetrated. It shows that the model experiments, if properly carried out, are very useful in testing the application of new improvements. Does it not also show that something can be done to minimise the effect of collision? What is the reason, then, that up to now nothing has been done to minimise the effect of collision?

It is impossible to build a ship with a flat nose, but the solution of the problem is to build the ship in such a way that her forepart should be sharp while she is propelled through the water, but that at the moment the nose of the ship touches the skin of another her fore part should collapse and present a flat surface. The power of the shock will consequently be distributed over a wide surface of the skin, bending inside ribs, beams, &c., without making a hole in the skin. Some part of the power of the shock will be exerted in collapsing the fore part of the colliding ship, and if this part is designed properly the collapse will absorb the greater portion of the blow. It would be most desirable that at the moment of touching the false nose should begin collapsing before the skin of the other ship begins to give way. The force required for collapsing should increase with the progress of this collapse, because more surface of the striking ship is engaged in resisting the shock—maybe it will be possible to altogether avoid damage to the vessel which is struck by so arranging the false nose that the full power of the shock will be utilised for smashing this nose. By that time the ship which strikes will lose the greater part of her speed, and the other will recede in a corresponding manner.

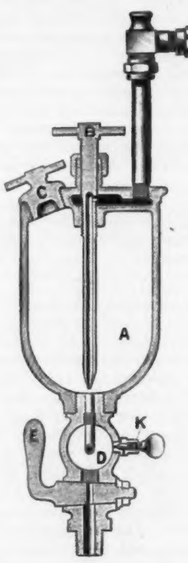


PLAN FIG. 2

Let us imagine that the nose of the ship is built as usual, and that the false nose is an additional part which can be put on or taken off when necessary. I imagine that it ought to consist of very thin sheets of steel, say one-eighth of an inch, and should run in front of the ship as shown upon the diagram. Many little ribs and stays inside ought to give enough strength to the skin to enable it to resist the force of the waves. The space between the false shell and the nose of the ship ought to be filled with some soft, fibrous substance—not powder. This substance is intended to play the *rôle* of a cushion and the shell will play the *rôle* of a pillow-case. After collision the false nose will present the appearance as shown in the diagram. The ship's nose will not be damaged, and as generally there is no cargo in the fore compartment of the ship in front of the collision bulkhead, it will be the work of a few hours to unfasten the bolts and remove the smashed false nose in order that the ship may continue her voyage as if nothing had happened.

LUNKENHEIMER'S AUTOMATIC GRAPHITE SIGHT-FEED LUBRICATOR.

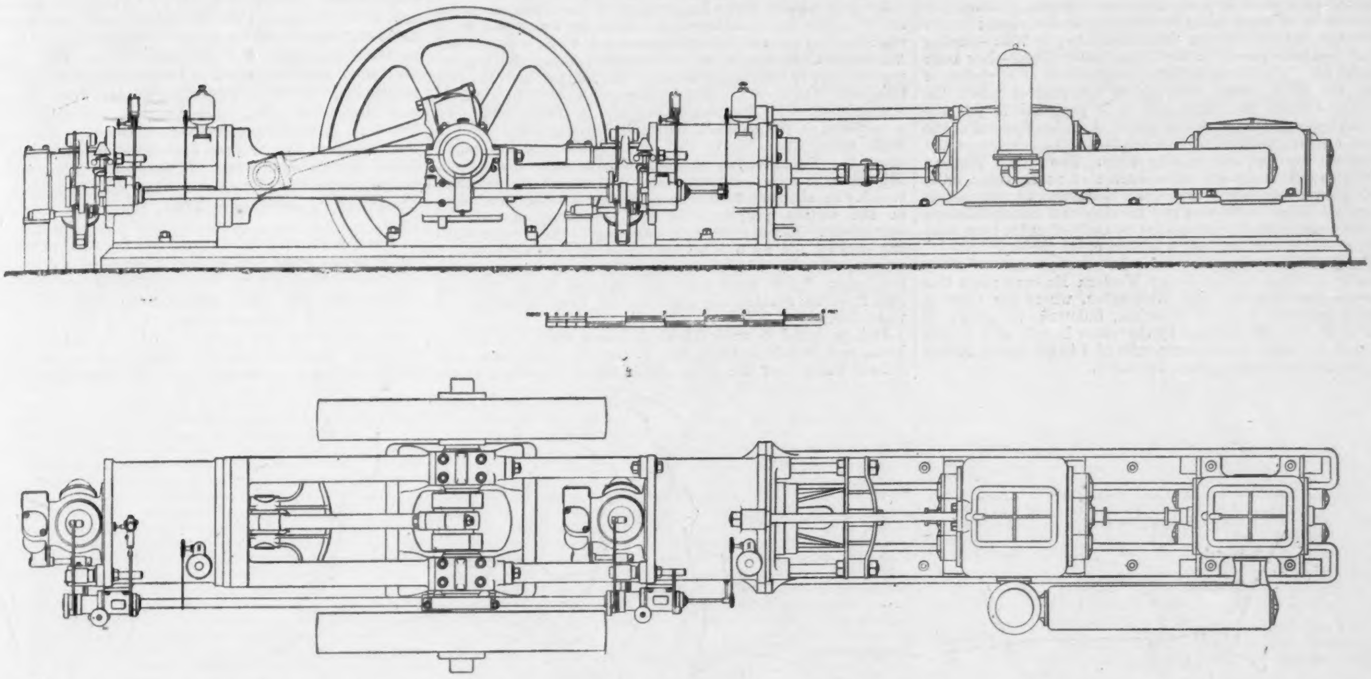
The accompanying engraving illustrates a self-acting valve for sight-feeding a determinable quantity of graphite to steam chests and cylinders, for use instead of oils for high pressures, and for lubricating where with very high pressures or with superheated steam oils are vaporised at once and do no good. The engraving shows only the section of the lubricator. In it A is the reservoir with which the graphite is filled through the plug-hole C. In the upper part of the lubricator cover is a small chamber to which steam is admitted, and from which it can only escape through the small hole leading into the tubular needle adjustable by the handle at B. When steam is turned on and the E opened, steam or water from the needle point carries the fine graphite with it through the tube into the space D, which has a small bull's-eye on either side. From the space D it passes to the steam chest. At K is a drain valve. The graphite lubricator is made by the Lunken Valve Company, Great Dover-street, London.



The Panama and Nicaragua Canals.—For the purpose of ascertaining some particulars of the reported consolidation of the Panama and Nicaragua Canal Companies, a representative of Reuter's Agency called upon Mr. J. R. Bartlett, president of the Nicaragua Canal Company, who has been engaged during the past two months in London and Paris carrying on negotiations, and is on the point of returning to New York. In reply to questions, Mr. Bartlett said:—"No such consolidation has yet taken place. But negotiations for a fusion of the interests of the two companies are in progress. As the matter has not yet received the consideration of the respective Boards, I cannot give details of the scheme. I may say, however, that the proposed arrangement includes a fusion of French and American interests, the Nicaragua Company purchasing the assets of the Panama Company, and both parties concentrating their influence and capital in the construction of a canal over the Nicaragua route, which is regarded by all parties as being the most feasible one. Such a consolidation of interests is regarded with great favour by banking interests in Europe and America, as removing every possible competition. Only one canal is needed to accommodate the maritime commerce now compelled to go round Cape Horn. As the canal is international in its scope, it will not only accommodate the ocean and coastwise tonnage of the United States, but the maritime commerce of other nations." In conclusion, Mr. Bartlett said the attitude of the various Governments concerned was exceedingly friendly.

LARGE TANDEM GAS ENGINE AND AIR COMPRESSOR

MESSRS. FIELDING AND PLATT, GLOUCESTER, ENGINEERS



200 I.H.P. GAS ENGINE AND AIR COMPRESSOR.

The above engraving shows a successful application of the gas engine to the direct driving of air compressors on a scale probably far beyond any hitherto attempted. The engine is one of Fielding and Platt's tandem pattern, and has two cylinders, their pistons being connected by a pair of side rods, the arrangement being such that an impulse to the crank at each revolution at equal intervals is obtained when working at full power. This produces very regular turning and a steady action on the compressor. Advantage has been taken of the compressed air to use a small quantity for the purpose of clearing the cylinder of exhaust gases, with very beneficial results as regards increase of power and fuel economy. The action of the scavenging arrangement is very positive, and its influence decidedly marked, when thrown into or out of action. These engines have been worked under various tests, and have, we are informed, given 182 maximum brake horse-power, at a speed of 150 revolutions per minute. This speed is somewhat excessive for an air compressor of the size in question, and, as a rule, the speed does not exceed 120 revolutions per minute. The engine is fitted with the Fielding patent self-starter, which, whilst very powerful, has the advantage of putting the engine quietly into motion before the starting explosion takes place. The engine is driven by producer gas from a 200-horse power gas plant, also made by Messrs. Fielding and Platt.

The air compressor was made by Messrs. S. H. Johnson and Co., of Carpenter's-road, Stratford, London, E. The whole plant was put in under the supervision of Mr. Howard Lane, of Birmingham, for a large metal works in South Wales, where it has been in daily operation during the last eight or ten months. Recently a number of tests for continuous working have been made with, we are informed, such highly satisfactory results as to leave no doubt as to the suitability of such an installation for work of this nature. The results as to economy must be considered to be exceedingly good. Messrs. Fielding and Platt are informed by the purchasers that they find, after long and continuous trials, that the consumption of coal is about 1 lb. per brake horse-power per hour. The coal used is anthracite from the Swansea district, and there can be no doubt that, for that neighbourhood in particular, fuel gas, and gas engines possess important advantages. The tandem type of engine appears also to be well adapted for electric lighting purposes, owing to the regularity and frequency of impulse obtained at a moderate speed. It would seem to be much better to obtain the required frequency of impulse by duplicating the cylinders than by doubling the speed of the engine. For instance, when running at 120 revolutions per minute, it will give as many impulses per minute as a single engine at 240 revolutions per minute, the wear and tear being reduced.

PROPOSED SHIP CANAL FOR CONNECTING THE BRISTOL AND ENGLISH CHANNELS.

By W. O. E. Meade-King, M. Inst. C.E.

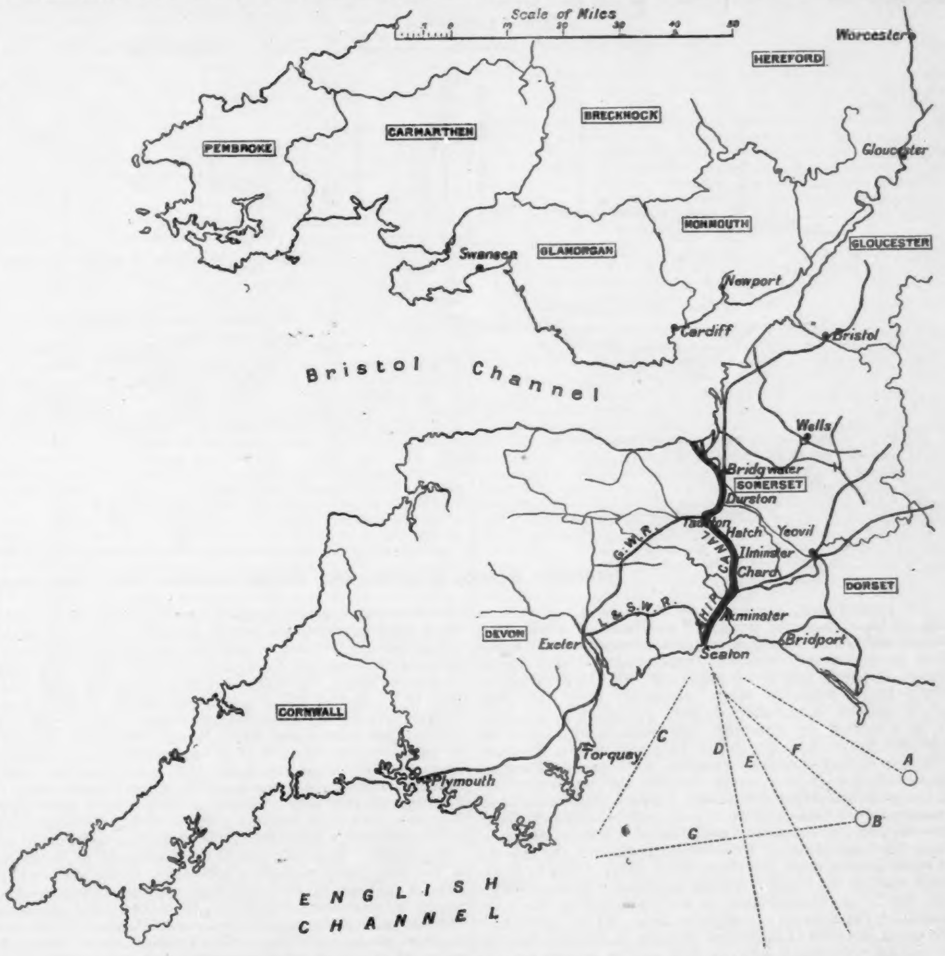
Various schemes have been suggested from time to time to connect the Bristol and English Channels by means of a waterway sufficiently large to take ocean-going vessels, but so far as the author of this communication knows, none of the schemes have ever been described in writing sufficiently fully to enable the public to judge of its practicability or financial prospects. The following description has therefore been committed to paper, and will, it is hoped, coupled with the drawings accompanying it, explain every point of interest and receive the favourable consideration of those to whom the shipping industry of the West of England is of so much importance. A certain portion of Somersetshire now drained by the river Parret and its tributaries, as is generally well known, is often subject to floods, and a portion of the canal now suggested, namely, from a point about two miles to the south-east of Taunton to its entrance in Bridgwater Bay, is so designed as to assist this part of the County in getting rid of its superfluous drainage.

Before describing the scheme further, it would be as well to point out the route it is proposed to adopt, and the reasons for selecting this position. The northern entrance to the canal would be in Bridgwater Bay, west of the point where the river Parret now flows into the Bristol Channel, and following the curve now taken by the Great Western Railway main line, would cross that railway about midway between Durston Junction and Taunton. In selecting this line, advantage has been taken of the lowest land, and also one railway crossing only is necessitated in the place of two, if the canal was made on the east side of the railway. In addition to which advantage, Bridgwater would be practically on the line of the canal, docks and wharves on which would be constructed to suit the requirements of what is at the present time an important port, how important can be seen from the shipping returns, which show total annual imports amounting to 163,645 tons, and exports, 51,194 tons, making a total shipping of nearly 215,000 tons.

About a mile from Taunton, docks might be constructed which would serve two purposes—in the first place, to take a portion of the trade of that important inland town, now wholly dependent on railways; and secondly, it would enable a sharp turn to be made in the canal, thereby avoiding high ground.

Leaving the Taunton docks, the canal would again follow the Great Western Railway, being the Taunton and Chard branch of that line, passing the towns of Ilminster, Chard, Axminster, Colyton, and Seaton. The Great Western line terminates at Chard Junction, when the line, the curve of which the canal would continue to follow, becomes the London and South-Western Railway, which would have to be crossed about two miles to the south-west of Axminster, after which the line of the river Axe might be adopted to its outlet in Seaton Bay. The total length of this canal would be about 42¾ miles, and the route selected, though rising at one part to as much as 300ft. above the sea, is nevertheless claimed as being the most direct, as well as the most practicable, that the country through which the canal would pass will admit of.

Amongst the many schemes that have been suggested, the one that has hitherto received what little favour any of them have found, was one, the line of which left the Bristol Channel east of the river Parret, thence proceeded to Yeovil, and from there to Bridport. This, no doubt, has some advantages, though outweighed by the disadvantages; whatever line is adopted, the watershed from which the rivers Parret and Axe derive their sources has to be crossed, and the lowest point is about 300ft. above the sea, and profiting by the experience gained in some of the difficulties encountered in the Manchester Ship Canal, the fewer the number of railway crossings necessitated the less the opposition to the canal in the first place; and secondly, the less the difficulties



PROPOSED BRISTOL CHANNEL AND ENGLISH CHANNEL SHIP CANAL entailed during construction. The line by Yeovil would mean at least four railway crossings, and possibly five; the line of the present scheme, only rising to the same height above the sea as the Yeovil scheme, has but two railway crossings.

Of course the height to which these railways would have to be raised depends entirely upon what headway is required by the class of vessel likely to make use of the canal; but in estimating the cost of the work a headway of 75ft.—similar to the headway given on the Manchester Canal—has been allowed for. High level bridges, composed of steel girders to carry the lines, would have to be constructed where the railways crossed the canal, and it is proposed to put the railways on embankments composed of excavation out of the canal, having gradients of 1 in 100, until the new line would strike the level of the existing lines. The Great Western Railway would have an embankment of nearly three miles in length on each side of the canal, containing approximately 1½ million cubic yards, and the London and South-Western Railway would have embankments each 1¾ miles long, containing together about half a million cubic yards.

The gradients proposed are not so steep as some of those already existing on the Great Western Railway main line between Burlescombe and Wellington, where for about a mile a gradient of 1 in 81 exists, followed by about 10 chains of 1 in 90, followed by the same length of 1 in 80, followed by rather more than a mile of 1 in 90, therefore 1 in 100 cannot be looked upon as excessive.

The river Parret, through all the low-lying part of Somersetshire, assumes very much the character of the rivers Mersey and Irwell, though on a somewhat smaller scale; it is a river having a very tortuous course, its bed and banks being composed largely of mud and silt, it is liable to heavy floods, when its banks constantly give way, very much to the detriment of the surrounding country. It is proposed to construct overflows from the canal into the Parret, and *vice versâ*, by which means the flood water can be kept under better control. Between the Taunton docks and the Great Western Railway, the river Tone—one of the principal tributaries of the Parret—would have to be crossed, and at this point it is proposed to admit the Tone into the canal by means of a weir, the water level of the latter being fixed accordingly. Once the canal was full, the amount of water passing down the Tone need never again be interfered with, as the canal would be furnished with an overflow into the Tone corresponding in level and size to the weir, admitting the Tone on the opposite side. All this portion of the canal, between 17 miles and 18 miles in length, which is to do duty during floods, as well as for inland navigation, is designed to be 100ft. wide at formation level—the remainder of the canal being 80ft. wide—and at water level a cess or benching is shown on either side, of 15ft.; therefore, if the excavation is got out with slopes of 1½ to 1, and the canal is 20ft. deep, flood water would begin to accumulate with a bottom width of 190ft., and the cutting being 30ft. deep, by the time flood water reached the surface of the land it would have a sectional area of 2050 square feet in addition to the natural area of the canal. A very considerable addition to the area now afforded by the river Parret, and by opening the sluices at the entrance to the canal in Bridgwater Bay, it would be a practical impossibility for any flood in the canal to rise to this height.

The widths given at formation level, namely, 100ft. for the northern portion of the canal from locks 1 to locks 3, and 80ft. for the remainder of the canal, are the actual widths of excavation, and as the sides would have to be protected, for preference with stone pitching, the space occupied by the pitching, say 2ft. on each slope, has to be deducted from the effective width of the channel, thus leaving 96ft. of effective width at the bottom between locks 1 and 3, and 76ft. between locks 3 and 26.

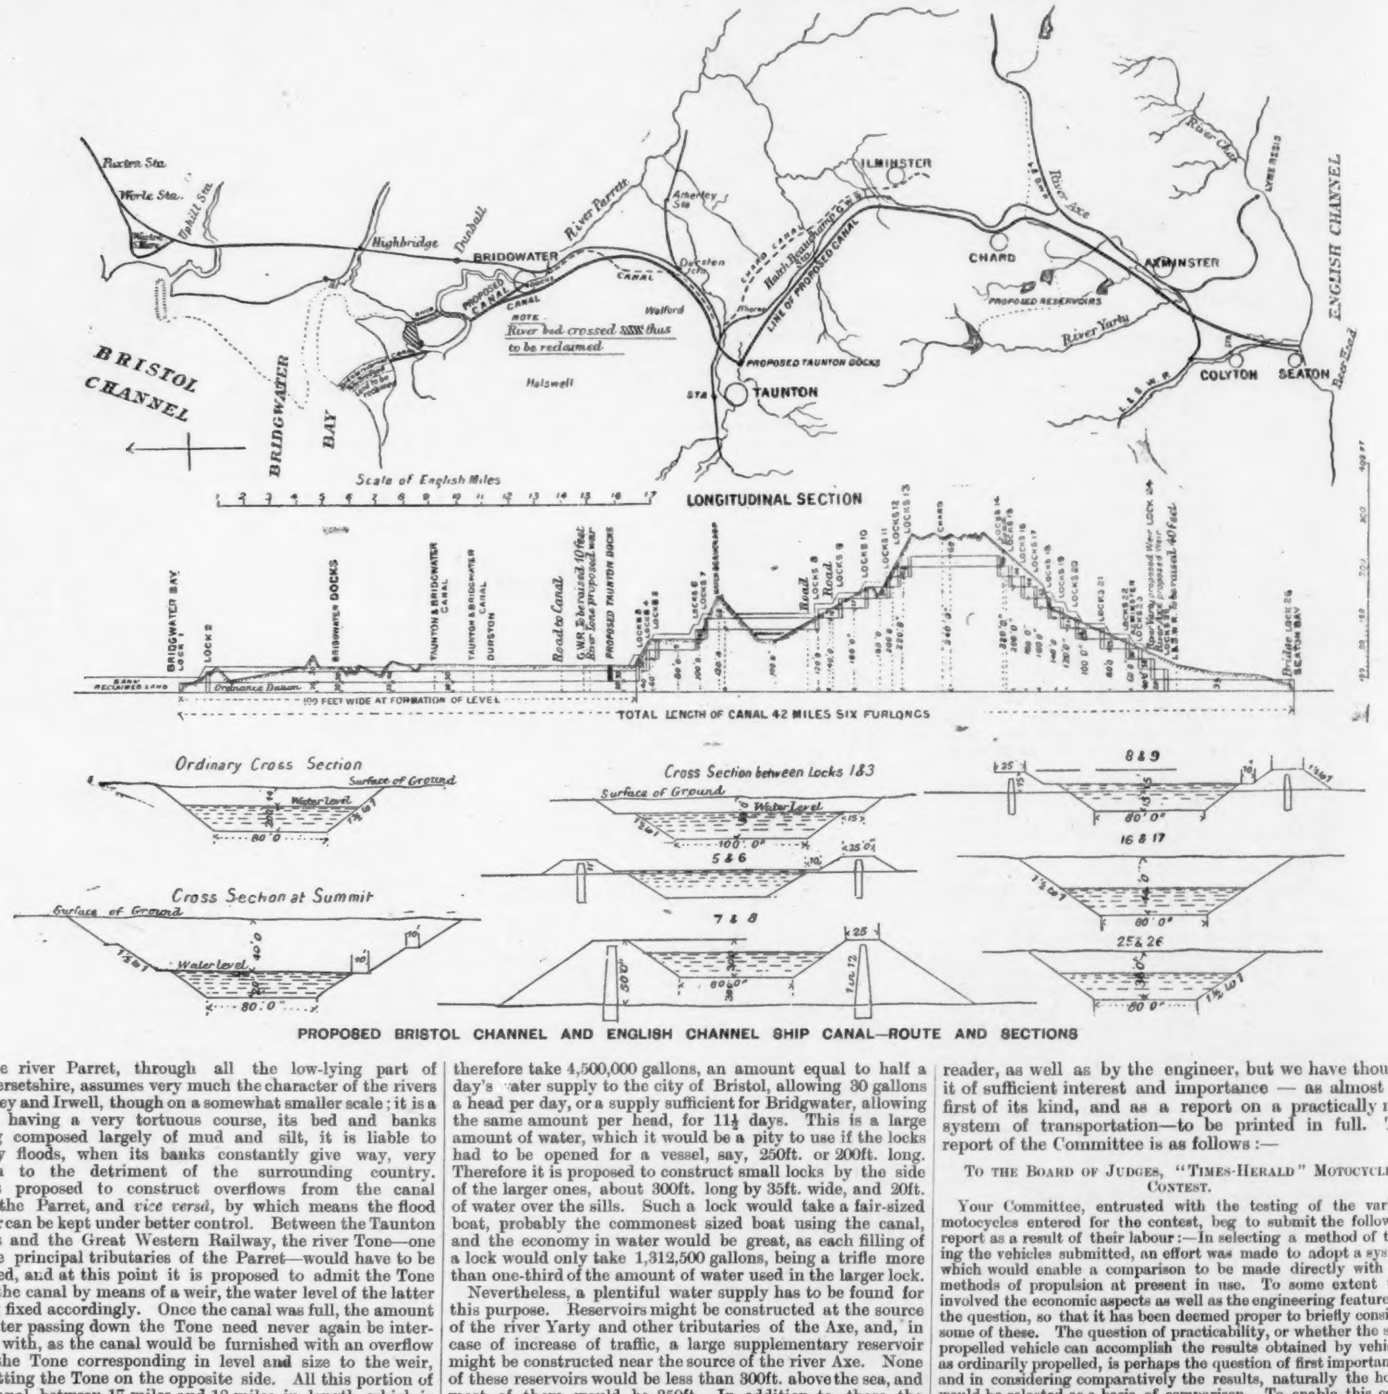
Between a point about a mile south of the Taunton docks and the other end of the canal at Seaton, the watershed, from which in this immediate neighbourhood the rivers Parret and Axe derive their supply, has to be crossed, being the highest ground already mentioned between the Bristol and English Channels; therefore the canal is reduced to 80ft. in width at formation level for economy's sake, and a cutting 60ft. deep is proposed at the summit, reducing the formation level to 240ft. above the sea. As this upper portion of the canal, about 3½ miles in length, is in deep cutting, and as any landslip would be such a serious matter if of magnitude sufficient to delay or obstruct traffic, every precaution has been taken in the section proposed for the prevention of such an occurrence. In the first place, the whole of the 60ft. in depth has been treated as if it was soft material, and as if no rock existed, the slopes being estimated for at 1½ to 1, and two benchings of 10ft. each have been allowed for as well, one 20ft. from the surface, the other at 40ft. from the surface, or water level.

It is proposed to work the whole canal with a system of locks, each lock to be 600ft. long by 60ft. wide, having at least 20ft. of water over the sills. Each filling of a lock would therefore take 4,500,000 gallons, an amount equal to half a day's water supply to the city of Bristol, allowing 30 gallons a head per day, or a supply sufficient for Bridgwater, allowing the same amount per head, for 11½ days. This is a large amount of water, which it would be a pity to use if the locks had to be opened for a vessel, say, 250ft. or 200ft. long. Therefore it is proposed to construct small locks by the side of the larger ones, about 300ft. long by 35ft. wide, and 20ft. of water over the sills. Such a lock would take a fair-sized boat, probably the commonest sized boat using the canal, and the economy in water would be great, as each filling of a lock would only take 1,312,500 gallons, being a trifle more than one-third of the amount of water used in the larger lock.

Nevertheless, a plentiful water supply has to be found for this purpose. Reservoirs might be constructed at the source of the river Yarty and other tributaries of the Axe, and, in case of increase of traffic, a large supplementary reservoir might be constructed near the source of the river Axe. None of these reservoirs would be less than 300ft. above the sea, and most of them would be 350ft. In addition to these the reservoir is still in existence which was constructed about 1848 for the purpose of supplying water to the Chard Canal, now disused. This reservoir might be brought into use again, and, considering that Somersetshire enjoys the reputation of having a greater annual rainfall than any other county of England, with the exception of the Lake district in Cumberland, there need be no fear concerning the water supply with six good reservoirs to feed the highest pond, four of which might be sufficient for the canal purposes, whilst the remaining two could be used as compensation reservoirs, if so desired.

Near Axminster the rivers Yarty and Axe would both have to be crossed, and as the canal would have to be at a considerably lower level than either of them for reasons to be explained presently, it is proposed to admit both rivers to the canal by means of weirs, thereby maintaining these rivers at their ordinary height, and also preventing their streams from carrying silt and other material into the canal.

(*To be continued.*)



PROPOSED BRISTOL CHANNEL AND ENGLISH CHANNEL SHIP CANAL—ROUTE AND SECTIONS

OFFICIAL REPORT ON THE AMERICAN HORSELESS CARRIAGE TRIALS.

In arranging for the competitive trials of motor carriages which were carried out at Chicago a few months ago, it was realised that the mere road performance of these carriages would not be a sufficient test of their comparative economy and efficiency or of their value as machines, and the Board of Judges therefore appointed a committee on tests, consisting of Mr. John P. Barrett, city electrician; Mr. John Lundie, civil engineer; and Mr. L. L. Summers, electrical engineer. These gentlemen designed the testing apparatus described and illustrated in The Engineer of November 22nd, 1895. All the carriages tested were described and illustrated in The Engineer of November 22nd, 1895, and January 3rd, 1896.

The report was only made public on February 16th, when it was published in the *Times-Herald*, as the proprietors of that paper, who originated the competition, did not wish the report issued until they were ready to print it in full in their paper. From the fact that the competition was a "popular" one, and that the results would be made known in a daily paper, the report has purposely been so written as to be understood by the lay reader, as well as by the engineer, but we have thought it of sufficient interest and importance — as almost the first of its kind, and as a report on a practically new system of transportation—to be printed in full. The report of the Committee is as follows:—

To the Board of Judges, "Times-Herald" Motocycle Contest.

Your Committee, entrusted with the testing of the various motocycles entered for the contest, beg to submit the following report as a result of their labour:—In selecting a method of testing the vehicles submitted, an effort was made to adopt a system which would enable a comparison to be made directly with the methods of propulsion at present in use. To some extent this involved the economic aspects as well as the engineering features of the question, so that it has been deemed proper to briefly consider some of these. The question of practicability, or whether the self-propelled vehicle can accomplish the results obtained by vehicles as ordinarily propelled, is perhaps the question of first importance; and in considering comparatively the results, naturally the horse would be selected as a basis of comparison. To enable this comparison to be made without involving the subject in undue technicalities, a brief digression dealing with the early investigations of the power of the horse may not be irrelevant; particularly as the horse has long been a source of motive power, and for this reason was early selected as a comprehensive unit of comparison.

The horse-power unit.—With the advent of the steam engine it was found necessary to compare the rate at which the engine could do work with the rate at which a horse could do work, in order that the purchaser of an engine could specify the power required in a unit he was familiar with. As the power the average horse was capable of exerting had been but indefinitely determined, experiments were made by James Watt to obtain definite figures, and for this purpose a weight of 150 lb. was arranged to be raised by the horse, when it was found that the weight could be raised at the rate of two and one-half miles per hour, or 220ft. per minute. Multiplying the weight in pounds by the feet travelled per minute, Watt obtained 150 × 220 = 33,000 foot-pounds per minute as the power which the horse could exert. This power could be exerted for eight hours per day, but for a fewer number of hours per day a higher rate of doing the work could be developed. Numerous experiments made since those of Watt have indicated that Watt's measurements were upon horses far above the average; the best authorities agreeing that the power of an average horse should be considered about 22,000 foot-pounds per minute. Upon this basis a table—"Trautwine's Pocket-Book"—of the pull a horse could exert and the corresponding speed in miles per hour would be as follows:—

Miles per hour.	Pull or Traction.	Miles per hour.	Pull or Traction.
Three-fourths	333·3	Two and one-fourth ..	111·1
One	250	Two and one-half	100
One and one-fourth ..	200	Two and three-fourths	90·9
One and one-half ..	166·6	Three	83·3
One and three-fourths	142·8	Three and one-half ..	71·4
Two..	125	Four..	62·5

It is evident that not only can the horse exert a heavy pull at a low speed, but that it is capable of exerting a wide range of pull, which makes it particularly suitable for the purpose of hauling vehicles. Experiments differ as to the maximum pull the horse can exert, and the conditions of footing, character of load, &c., greatly affect the results. For the purpose of determining roughly a probable value, an express horse of average type was tested by your Committee, and, without resorting to violent methods of persuasion, the maximum pull obtainable was found to be about 250 lb. It is probable that 400 lb. is about the maximum with a good horse. On the other hand, when the pull is light a considerable range of speed may be obtained, and a measure of the power exerted by the horse at all times may be obtained by multiplying the pounds pull by the speed in feet per minute. Dividing this by 33,000 gives the ordinary unit known as the horse-power. The figure of 33,000 foot-pounds per minute obtained by Watt is commonly adopted as the number of foot-pounds per minute constituting a horse-power. The determinations actually made of the pull required of a horse in pulling a vehicle are not very numerous nor authentic, as, owing to the fact that the pull is apt to be irregular, many difficulties are encountered in measuring it and no great accuracy is attainable. A comparison of the motocycle with the performance of a horse involved then a measurement of the pull the vehicle could exert and a determination of the speed the pull was exerted at. A testing machine was accordingly designed with the primary object of measuring these factors. The power of the vehicle was readily obtained from these by multiplying the pounds pull by the feet per minute travelled. This being divided by 33,000 would then give the mechanical horse-power exerted by the vehicle on the rim of the wheel at any instant. As this power measurement of the vehicle would determine its ability to propel itself under different conditions, a measurement of the fuel consumed in accomplishing this would enable the item of cost to be obtained. The net results, therefore, sought were how much power would be available at the rim of the wheels for a given expenditure of money. In the case of a gasoline engine a measurement of the gasoline consumed in a given time while the motocycle was exerting a given power would enable this cost to be determined directly. In the electrically propelled motocycle a measurement of the power consumed in producing a given power at the rim of the wheel would enable one to calculate the cost of propulsion when the cost of electrical power for charging the batteries was known. In addition to considering the cost of producing a given amount of power at the rim of the driving wheels, it was considered advisable to determine if possible the losses between the driving motor and the rim of the wheels. These determinations would show how efficiently the power generated by the motor was transmitted to the wheels of the vehicle. The various methods adopted of regulating and controlling the speed and power of the vehicle might also affect the consumption of fuel, and result in a less amount of power being available for a given amount of money expended in fuel. Very accurate data are available concerning the usual types of motors, similar to those used for propelling vehicles. These data are confined almost entirely to the use of the motors for stationary purposes, however, and very little information is extant regarding their application to vehicles.

Fuel tests.—Under these circumstances somewhat extended tests were made to ascertain the consumption of fuel and performance of the vehicles under the various loads apt to be imposed in practice. In order that the same conditions might exist for all gasoline vehicles under test, they were all supplied with gasoline from the same barrel, the density of which was found to be 0·688. No effort was made to obtain a particular density of gasoline, as it was deemed best to use that ordinarily to be obtained from the retail dealer. Cost of gasoline has been estimated at 2 cents—1d.—per pound in deducing the results shown in the appended table. The cost of electrical energy has been estimated at 10 cents—5d.—per kilowatt hour. The storage batteries are assumed to have an efficiency of about 75 per cent., making a cost per horse-power hour delivered to the motor of 10 cents.

Maximum pull of vehicles.—In order to still further compare the performance of the motocycles with that of the horse, efforts were made to determine the maximum pull which the vehicle could exert as compared to that of the horse. It is evident this would only be of interest in determining the performance of the vehicle when operating under extremely unfavourable conditions, and in this connection it is only fair to add that the vehicles submitted were all designed for a light passenger service and not to exert a heavy pull, so that a medium pull exerted at a high average rate of speed was the object sought rather than a heavy pull under adverse conditions. For determining this feature the pull on the motocycles was increased until the limiting conditions were reached, with the results shown. It is apparent that the heaviest pull exerted, viz., that with the Duryea vehicle, amounted to only 187 lb., as compared to 400 lb. which a single horse could exert. It was not possible in any of the tests made to slip the driving wheels, so that the traction in all cases was ample, and if a greater driving power had been available by means of reducing gearing or otherwise, it would probably have been possible to obtain a correspondingly high result. In the case of the belt-driven machines of the Benz type, the limit was usually reached when the belts slipped. Owing to the defective conditions of the belts on the Macy machine, which possessed one of the most powerful motors of any of the vehicles submitted, the maximum effort was not obtainable. The Lewis motocycle was equipped with a special reduction gear, enabling a very heavy pull to be produced. An effort to obtain this heavy pull from the vehicle resulted in the breaking of the driving chains. Under these conditions it is hardly fair to consider the results as the best obtainable. In the machines directly-geared, any attempt to obtain heavier pulls than those given resulted in stalling the motors. The pull obtained with the electrical vehicles is, of course, only limited by the heating effects of the excessive current required. It will be observed that there is a wide difference in the consumption of gasoline by the various engines submitted. This is naturally to be expected when the types of engines are considered. In the case of the Lewis and the Haynes and Apperson vehicles, the cycle is such as to give an explosion every revolution, the piston itself uncovering the exhaust port, this type of engine being variously known in stationary practice as the Single, Sintz, or Day cycle. The exhaust from these engines was so densely laden with unconsumed carbon that an exhaust pipe and fume blast were required to convey the fumes from the testing-room. This simply bears out the well-known fact that this type of engine, giving an explosion for every revolution, while possessing many advantages, has a very low economy, due to the improper combustion of the fuel supplied. The other motors presented were almost all operated upon the Otto cycle. In the Benz type of motor the gasoline was thoroughly carburetted before being admitted to the cylinder, while in the Duryea and others the gasoline was vaporised directly at the cylinder. The results obtained, therefore, enable a partial comparison to be made between these methods of utilising the gasoline. It is to be regretted that owing to a derangement of the igniting mechanism in the Duryea engine higher power tests were not possible with this vehicle. It is a well-known fact in gas engine operation that the economy of the engine at light loads is, if anything, inferior to the steam engine under similar conditions. In the application of the gas engine to a motocycle the economy is particularly low, for the reason that a considerable proportion of the power is sacrificed in driving the mechanism. Owing to this feature the consumption of gasoline per horse-power hour at the rim of the wheel is quite large when the motocycle is operated under an ordinary load. Thus with a load requiring about three-quarters of a horse-power for its propulsion, it is evident that as high as one and one-half horse-power may be required in the engine in order to overcome the friction of the mechanism. If the motor is designed to give three or four horse-power at the rim of the wheels, the motor is lightly loaded under the ordinary conditions, and the economy as a result is very low. In this connection the Benz type of vehicle presents another interesting feature of comparison. These vehicles are provided with but two ranges of speed when the gas engine is running at its normal speed, and in order to increase the range of control the supply and proportion of the mixture of air and gasoline is varied. This is accomplished by a regulating valve controlled from the driver's seat. The explosive force of the mixture is readily controlled in this way, and a wide range of speed is thus given to the vehicle without the necessity for complicated mechanical devices for speed regulation. This simplicity and ease of control may, however, be purchased at the expense of economy, as will be apparent from the tests at various loads. It is evident that under the best condition of load a horse-power can be produced at the rim of the wheel with almost one-fourth the rate consumption of gasoline that it can under the worst conditions. With a type of vehicle such as the Duryea, where the speed of the gas engine is maintained constant and the speed regulation is affected by changeable gearing, the economy with variable speed of the vehicle is dependent entirely upon the load carried by the engine. Under some conditions, therefore, it is possible for a motocycle to ascend grades at the same speed as upon a level road and with the same consumption of gasoline. In other words, the loading of the engine may so increase the efficiency that it will enable it to give the increased power without increase in the consumption of gasoline. As far as possible it was endeavoured to ascertain if the jolting of the vehicles using a carburetter would affect its action—in other words, if the explosive character of the mixture was varied by the effects of the vibration of the vehicle. So far as could be determined, no effect was noticed in this respect; the carburetter apparently at all times supplying an even mixture. The location of the driving engine and the method of transmitting the power to the driving mechanism greatly influences the amount of vibration there is to the vehicle. In the Benz type of vehicle the single-cylinder engine, giving an explosion at every second revolution, is mounted with the cylinder at right angles to the axle of the driving wheels. The effect is to cause considerable vibration, and unless special means are adopted for counteracting this, it is transmitted to the body of the vehicle, resulting in more or less discomfort to passengers at the time of starting, although afterwards it is not so noticeable. In the Duryea vehicle the two driving cylinders are parallel to the axle of the driving wheels, and any reactive effect from the cylinders produces a vibration transversely. The vehicle of Haynes and Apperson is provided with two cylinders, one on each side of the crank shaft, and the reactive effect is greatly diminished. From the consideration of these questions, it would appear necessary to use more than one cylinder to eliminate vibrations, and preferably these cylinders should be arranged upon opposite sides of the driving shaft in order that the reactive effect may be entirely balanced and the vehicle freed from vibratory effects when the engine is running, though not propelling the vehicle.

Electric vehicles.—In considering the electric vehicles it is evident that in using a variable current from the storage batteries as the discharge rate is increased beyond the normal, both the life and efficiency of the battery will be diminished. In the Morris-Salom vehicle the batteries were rated at fifty ampère hours, with a discharge rate of five ampères. When discharging at a rate of twenty-two ampères it is evident that the available capacity of the cells will be greatly diminished. It is perhaps unfair to assume therefore that the efficiency will remain constant. While the mechanical efficiency is higher with a heavy load, the electrical efficiency as a whole may be diminished. The correction necessary for these factors will depend so largely upon particular conditions that no allowance has been made for them. The assumption of 75 per cent. efficiency in the batteries will be a fair average for normal conditions. The cost of electrical energy will also vary with the conditions, so that both of these factors must be considered in estimating the cost of operation. The heavy depreciation of the batteries when subjected to excessive discharges will also constitute a charge against cost of operation.

Single and double motors.—An interesting comparison may be made between the Sturges vehicle and that of Morris and Salom. Both of these vehicles are equipped with the same type of motor, the Sturges vehicle being propelled by a single motor of 3-horse power, while that of Morris and Salom is propelled by two 1½-horse power motors. A single axle with the wheel solidly mounted, the carriage being carried by the journals on this shaft, after the pattern of a car journal, is the method of driving adopted in the Sturges vehicle; while in the Morris and Salom vehicle the pinion on the motor is geared directly to the driving wheels, the wheels being provided with ball bearings, and every effort being made to diminish friction. The tests indicate that with the best workmanship possible, the two motors have but a slightly higher efficiency than the single motor, though the mounting of the single motor is in a measure crude. The electrical and gear losses with two motors would, of course, be greater than with a single motor. The advantages of the series—parallel control of the motors when storage batteries are used and may be grouped to regulate the voltage, does not, therefore, seem necessarily to be a factor of sufficient importance to warrant the adoption of two motors. Apparently the only other factor to particularly commend this arrangement is the elimination of a differential gear for enabling the wheels to travel independently of each other when curves or corners are being turned. In driving with a single motor of any type it is evidently necessary to provide a means for driving the wheels independently of each other, as otherwise a binding action on curves would result. The method adopted in almost all the gasoline vehicles presented consisted of some form of differential gear, each driving wheel of the vehicle being separately connected by means of a sprocket chain to the same countershaft.

Wheel experiments.—A series of experiments was made with a view to determine the power consumed in wheel resistance, consisting of axle friction and so-called rolling friction, an effort being made to separate these elements, with considerable success. The method adopted in determining the power consumed in wheel resistance was to drive the wheels while resting on a drum of hard wood whose surface was smooth, and which was so heavy as to show no perceptible distortion under the loads imposed, the power being measured at the periphery of the drum by the product of its speed and the tension on the dynamometer, to which the axle was connected. In this connection it may be noted, as might have been expected from theoretical considerations, that the total dynamometer pull under uniform motion was found constant at all moderate speeds. In separating the effect of axle friction from that of other losses, observations were made by suspending a load from the axle of a single pair of wheels by a cradle and noting its deflections, which were multiplied by a long pointing arm, making quite a sensitive cradle dynamometer. The same cradle loads and axle were used with different wheels, and by comparing deflections under different circumstances an approximation to friction of direct or vertical bearing and friction of side thrust was obtained. The analysis of loss due to the action of other parts of the wheel than the axle is only relative, and was found by comparing the action of different tires mounted on wheels built up in the same way, having wooden hubs, spokes, and felloes.

Separation of axle and tire resistance.—In the overcoming of axle friction the leverage of the radius of the wheel compared with the radius of the bearing gives a ready method of comparing the values of different mechanical bearings and of lubricants, and in order to appreciate thoroughly the problems involved in wheel resistance, losses due to axle friction must be recognised as separate and distinct from losses due to lack of resilience in the tires and other parts of the wheels. Some writers have assumed that summing axle and resilience losses together under the term "rolling friction"—a hazy term at best—was all that could be done, owing to the difficulty of separating the two. We believe the method adopted in making the separation to be novel, and one indicating a line of future experiment in this direction, which may be of value. In discarding, then, the term "rolling friction," as indicating a compound action, the losses of power in wheels may result from the following factors:—(1) Axle bearing friction. (2) Axle thrust friction. (3) Lack or resilience of tires and other parts of the structure of the wheel. As noted above, we were unable in the limited range of our experiments to analyse the third factor as we would have liked to have done, and thus the tire determinations involve a possible factor of the resilience of other parts of the wheel. (Resilience is here considered to mean the capacity of an elastic body to store and give out work done upon it. Table No. 1 gives the actual data and reduced results of the tests.) These results may not seem to meet preconceived views, and it may therefore be well to briefly analyse the results in order to indicate what may be deduced from a close consideration of the wheel problem.

TABLE NO. 1.—*Wheel Resistance Tests.*

Number of test.	Nature of axles.	Nature of tires.	Mean dia. of bearings.	Radius of wheels loaded.	Weight of pair of wheels.	Total load, including wheels.	Pull at tire due to axle friction.	Total pull at tire producing uniform motion.
			in.	in.	lb.	lb.	lb.	
1	Collinge	Steel	1⅛	24·5	68	659	5·4	8·84
2	Ball bearing	Steel	1¾	21·75	—	452	—	2·86
3	Collinge	Solid rubber	1⅛	18·9	75	657	2·64	5·49
4	Ball bearing	Solid rubber	1$\frac{13}{32}$	24·2	—	645	—	2·36
5	Collinge	1¾in. pneumatic (inflated)	1⅛	22·5	67	657	1·78	7·37
6	Collinge	1¾in. pneumatic (deflated)	1⅛	22·1	67	598	—	10·57

Analysis of wheel resistance.—One naturally seeks an answer to such practical questions as, What kind of a bearing ought I to use? What tire is best suited for certain work? What ought to be the diameter of a wheel for efficient service? And others of like nature. The limits of this report will not permit of more than an indication of the bearing of these experiments upon such questions. The following results may, however, be deduced from a consideration of the above data:—

Table No. 2.

Pulls per 1000 lb. of total load required to overcome lack of resilience in wheels under examination. (See tests, 1, 3, 5, and 6, Table No. 1).

5·23 lb. on steel tire.
4·34 lb. on solid rubber tire.
8·5 lb. on pneumatic tires inflated.
14·6 lb. on pneumatic tires deflated.

Let it be noted that these pulls, being due principally to the material of the tire when the rest of the wheel is well made, are not reduced by leverage as in the case of axle friction, as the moment used in overcoming the resistance is the same as the moment of the resistance. As before mentioned, the axle friction, acting as it does near the centre of the wheel, is overcome by a pull which is inversely proportional to the radius of the wheel. In order, then, to properly compare axle frictions, they should be reduced to pulls at equal distances from the centre of the wheel. Deducing, then, from experiments, we have:—

Table No. 3.

Pulls per 1000 lb. of load on bearings of Collinge axles reduced to uniform radius of 12in. (See tests 1, 3, and 5, Table No. 1).

18·7 lb. with steel tires.
7·2 lb. with solid rubber tires.
5·7 lb. with pneumatic tires.

How tires affect results.—The question is naturally asked, What have the tires to do with the result? This leads to the consideration of what carriage builders call "set" and "gather" in wheels, both being designed to compensate for the distortion of a vehicle in operation. The "set" is a vertical adjustment of the axle, so that when the wheels are under working load the tread of the tire will be horizontal. The "gather" is a lateral adjustment of the axle, so that when the wheels are under average traction they will be parallel to the direction of motion of the vehicle. In the case of a steel tire, unless the axle and tire adjustment is perfect, there is induced in the axle a side thrust which accounts for the abnormal axle friction shown above with the steel tired wheels used. In the cases of the solid rubber and the pneumatic tires, the tire allows a more or less perfect adjustment to be taken naturally. The loads in tests 1, 3, and 5, Table No. 1, were practically the same and the axles were identical, and in the matter of axle-bearing friction the same coefficients apply. Thus with the pneumatic tires the coefficient of 5·7 lb. per thousand at a radius of 12in., Table No. 3, represents bearing friction and very little, if any, thrust friction. Reduced to the radius of the bearing the friction figures 120 lb. per 1000 lb., giving a coefficient of friction between surfaces not too well lubricated of 0·12, which corresponds with the result of well-known friction experiments. The difference between 18·7 lb. on the steel tire wheel and 5·7 lb. on the pneumatic, or 13 lb., represents the pull per 1000 lb. at a radius of 12in. necessary to overcome the action of side thrust. Thus the elimination of side thrust is a much greater factor in the reduction of power consumed by the wheels of a vehicle than the reduction of the friction of vertical bearing on the axle.

Proper diameter of wheels.—In the cases of tests 2 and 4, Table No. 1, it was not possible to separate axle friction and resilience, but it seems a fair deduction to draw that with tires eliminating side thrust and with well designed bearings, the power consumed in such a wheel system is principally due to resilience. This leads to the question of the determination of the proper diameter of wheels. The pull required to overcome axle friction varies inversely as the radius of the wheel. This pull may become so small with proper bearings that even doubling the radius will only reduce it a mere fraction, while reducing the radius one-half will only increase the pull by a trifling amount. The pull due to resilience does not depend on the radius. Thus economy points to a diameter of wheel which is not determined by the caprice of the maker or the notion of the purchaser. Elsewhere in this report it will be seen that other elements in the propulsion of a vehicle may outweigh the reduction of pull due to axle friction given by an increased radius of the wheels. The kind of road a wheel is intended to travel over has a bearing upon the subject. The benefit of the pneumatic tire in reducing the amount of work performed in the driving of a vehicle is treated elsewhere in this report. That it was not found in the friction tests may be disappointing to those who had preconceived ideas regarding the matter.

Energy expended in propulsion.—The resistance a vehicle offers to motion may be divided into three principal elements—viz., (1) Kinetic resistance, or that which is common to all mass moved through any given medium; (2) internal resistance, or that due to the construction of the vehicle itself; (3) road resistance, or that external resistance due to the nature of the road the vehicle travels over. The first can be calculated from known laws of kinetics; the second our experiments bears on; the third contains elements for further investigation than it has so far received. In this connection it was intended to have tests made of the resistance due to various road surfaces by measuring the energy input of the electric vehicles competing. The heavy fall of snow at the time of the Thanksgiving Day race, November 28th, 1895, interfered with these plans, and an accurate profile of the course, showing all grades, nature of paving and roadbed, which had been prepared, was rendered useless for such determinations at that time. It is to be hoped that further experiments will be made along this line to supplement what limited information is now available, and that future promoters of motocycle races will improve such opportunities for adding needed information in this and other directions. In the following brief analysis of energy expended in the propulsion of a vehicle against the three elements above noted, application of the principles involved to the case of an assumed vehicle may possibly be the best method of making the subject clear. Let us then assume a vehicle as follows:—Weight, 1600 lb., divided 1200 on drivers and 400 on steering wheels; speed to be attained, ten miles per hour, or 880ft. per minute; surface exposed to air resistance, 20 square feet; elastic tires and ball-bearing axles; motor, 3-horse power; efficiency, 50 per cent.

Taking up then the element of kinetic resistance, we divide it as follows:—(*a*) To give the desired motion to the mass: To this end a force is required which will be found by dividing the energy of direct motion—found by multiplying the mass in pounds by the square of the velocity in feet per second and dividing by twice the rate of acceleration of gravity—by the distance in which it is desired to accelerate to the required velocity. The energy of direct motion of the assumed vehicle moving at the rate of ten miles per hour is therefore:—

$$\frac{1600 \times 14{\cdot}66^2}{2 \times 32{\cdot}2} = 5340 \text{ foot-pounds.}$$

If it be desired to accelerate to this velocity in a distance of 200ft., then the applied force must be, for overcoming this element:—

$$\frac{5340}{200} = 26{\cdot}7 \text{ lb.}$$

Should it be necessary to stop the vehicle in a distance of 50ft., the retarding forces acting upon it, to give this result, would equal a force of

$$\frac{5340}{50} = 106{\cdot}8 \text{ lb.}$$

(*b*) To overcome the component of gravity in climbing a gradient: For this purpose a force is required which will be found by multiplying the weight of the vehicle by the sine of the inclination of the gradient—approximately the percentage of gradient. Thus our assumed vehicle would require 0·05 of 1600 = 80 lb. force to overcome the component of gravity on a 5 per cent. inclination. In descending such a gradient a pull of 80 lb. would be exerted by gravity, and if, say, only 32 lb. were required to keep the vehicle moving at a uniform speed, the brake would have to counteract the difference of 48 lb., and thus energy would have to be dissipated at the rate of 48 × 880 = 42,240 foot-pounds per minute. Thus, in descending a 2 per cent. gradient, giving a gravity pull of ·02 × 1600 = 32 lb., no energy is dissipated. In a gradient in excess of 2 per cent., part of the energy of position must be dissipated, by application of the brake, to prevent undue acceleration of the vehicle. (*c*) To overcome the resistance of the air: For this purpose a force varying as the square of the velocity is required, and for moderate velocities this is found approximately per square foot of surface exposed by dividing the square of the velocity in miles per hour by 200. This, for the assumed vehicle, not considering wind, would be

$$\frac{100}{200} = 0{\cdot}5 \text{ lb. per square foot,}$$

and for 20 square feet, the number we assume, we find 20 × 0·5 = 10 lb. pull necessary to overcome air resistance. The work done in overcoming this is wholly dissipated.

Internal resistance.—Taking up now the question of internal resistance, we subdivide it as follows:—(*a*) Friction of axle; (*b*) friction of tire skidding; (*c*) lack of resilience of tires and other parts of the vehicle; (*d*) friction of mechanism in self-propelled vehicles; (*e*) friction of brakes when applied. These elements have been made the subject of discussion resulting from the experiments made on the various vehicles submitted for test, and are more or less fully treated of in the tests and deductions presented elsewhere in this report.

Pull of assumed vehicle.—In the assumed vehicle we have a power developed at the rims of the driving wheels of 50 per cent. of 3-horse power, or $\frac{33{,}000 \times 3}{2} = 49{,}500$ foot-pounds per minute. At an assumed speed of ten miles per hour this would give a pull of $\frac{49{,}500}{880} = 56{\cdot}3$ lb. capable of being exerted. This is the pull actually given out at the rims of the driving wheels, and is supplemental to the factor of energy expended in internal mechanism and wheel resistance of drivers. It has to overcome in addition to external resistance the resistance of the steering wheels and other elements of internal resistance not involved between the motor and the rims of the driving wheels. In the assumed vehicle without going into delicate details this would be, say,

$$\frac{400 \times 10}{1000} = 4{\cdot}0 \text{ lb.}$$

It may be here noted that an excessive "gather" of the wheels will produce a component lateral skidding action of the tires, which may produce quite a large resistance.

Road resistance.—Very little accurate data on road resistance is available, but its elements may be pointed out and deductions made showing how important a factor good roads are in the consideration of economical transportation, whether by means of the motocycle or otherwise. We subdivide, then, road resistance as follows:—(*a*) Adhesion of roadbed to tires: This is appreciated when moving through wet clay, and there are good reasons for believing that on certain pavements adhesion is quite a factor in resistance. (*b*) Distortion or low resilience of the roadbed: This constitutes a large factor of resistance to the propulsion of a vehicle, as a bad road may offer ten times the resistance to motion which a smooth one will. In this connection it was expected to have obtained valuable data from observations made on the electrical motocycles and the profile of the course as before mentioned, but as this was impossible, a reference to former experiments determining total traction of wheels on different characters of roads will indicate the relative resistances between different roadbeds.

Traction on roads.—The following table is from Molesworth's "Pocket-book":—

Resistance in Pounds per ton—2240 lb.—on different roads, exclusive of Gravity.

Stone tramway	20
Paved roads	33
Macadamised roads	44 to 67
Gravel	150
Soft, sandy and gravelly ground	210

Presumably these determinations were made at low speed, so that the element of air resistance may be neglected. The table shows a pull of 9 lb. per 1000 on a stone tramway, which corresponds fairly well to the surface on which our wheel determinations were made. Undoubtedly the axles were of the ordinary type and the tires of steel; thus in this case the resistance was almost wholly that of axle friction and lack of resilience, and corresponds to results under "wheel determinations." On a macadamised road the pull as given by the table averages 25 lb. per thousand. Thus the difference between this and 9 lb., the result on the stone tramway, or 16 lb. per 1000, gives the element of road resistance on such a roadbed. Country roads on the basis of this table would probably correspond to the higher figure given for macadamised roads; this is equivalent to 30 lb. per 1000. Deducting the stone tramway result we have 30 − 9 = 21 as an approximation to the resistance per 1000 lb. of load which may be expected on the common roads. The assumed vehicle thus would have a constant road resistance to overcome, in addition to other resistances, of

$$\frac{1600 \times 21}{1000} = \text{about } 34 \text{ lb.}$$

were it fitted with steel tires and ordinary axles. But, as will be seen in the following section (*c*), the use of pneumatic tires on a rough road might readily reduce this resistance considerably, say to 20 lb.

Advantage of pneumatic tires.—(*c*) Climbing over minor obstructions on a hard road: This constitutes resistance which, while of short duration in individual cases, becomes an element of considerable importance if such obstructions are frequent. Thus a discussion of this action will make clear the advantage of the pneumatic tire. Supposing we have a wheel with a steel tire of 24in. radius and it encounters a stone 1in. in height; then it is evident, unless the stone is crushed or pressed into the tire or roadbed, the load on the wheel will have to be raised over the stone. By a simple calculation it will be seen that this involves the momentary climbing of a gradient of 1 in 3½. In the case of the assumed vehicle with a load of 600 lb. on one driving wheel, this would require a pull of

$$\frac{600}{3{\cdot}5} = 172 \text{ lb.}$$

This increased momentary pull is overcome by the inertia of the vehicle in motion. To start with such stones in front of the wheels would require perhaps more static pull than the vehicle would be capable of exerting. This is well illustrated when to prevent a vehicle running down hill comparatively small obstructions placed in front of the wheels suffice to accomplish the result. As the vehicle passes over such an obstruction the energy of position is given back partially in energy of motion; but as this is only accomplished by the action of gravity, the element of time is involved to such an extent that if the vehicle no sooner climbs one obstacle than it encounters another, energy is dissipated to a great extent. With a pneumatic tire such an obstacle would sink into the tire half an inch or more, and so reduce the momentary grade in proportion. Where a road is encountered having many such obstructions the energy saved by the use of pneumatic tires will be considerable, as not only are the momentary gradients less, but energy is stored in the tire by its elasticity normal to the direction of pressure. This must not be confused with the results showing low resilience of a pneumatic tire under tangential pull.

Resistance to motion.—We may now sum the results as deduced from the consideration of the assumed vehicle, as follows:—

	Constant.	Incidental.
Kinetic resistance—		
Acceleration	—	26·7
Max. grade, 5 per cent.	—	80
Air	10	—
Internal resistance apart from that consumed between motors and drivers	4	—
Road resistance	20	100
Total	34	206·7

We found our assumed motor to be capable of exerting at a speed of ten miles per hour at pull of 56·3 lb. at the rim of the driving wheels. Part of the incidental resistance noted above may be expected during the progress of any trip of a vehicle, and if economy is considered, it may not be advisable to purchase pull at the expense of speed, but rather to design motors for the specific work they may be called upon to perform.

Results from consolation race.—To illustrate this we might cite the run of the Mueller Benz motocycle in the *Times-Herald* consolation race of November 2nd, 1895. The distance travelled was ninety-two miles over comparatively light grades and ordinary roads, being from Jackson Park, Chicago, to Waukegan and return to Lincoln Park, Chicago. The net running time was 8 hr. 44 min., and the gasoline consumed 31·52 lb. This indicates a speed of 927ft. per minute and a consumption of an average of 1 lb. of gasoline required to run 15,450ft. In the tests shown above we found this machine at a speed of 984ft. per minute and a pull of 73·4 lb., developed 1,268,000 foot-pounds of work at the rim of the driving wheels per pound of gasoline. Again, at a speed of 1168ft. per minute and a pull of 34·7 lb. it developed only 588,000 foot-pounds. If the above economical development of energy were maintained the average pull throughout the run would be

$$\frac{1{,}268{,}000}{15{,}450} = 82 \text{ lb.}$$

If, on the other hand, the latter development of energy be assumed, the average pull would be

$$\frac{588{,}000}{15{,}450} = 38 \text{ lb.}$$

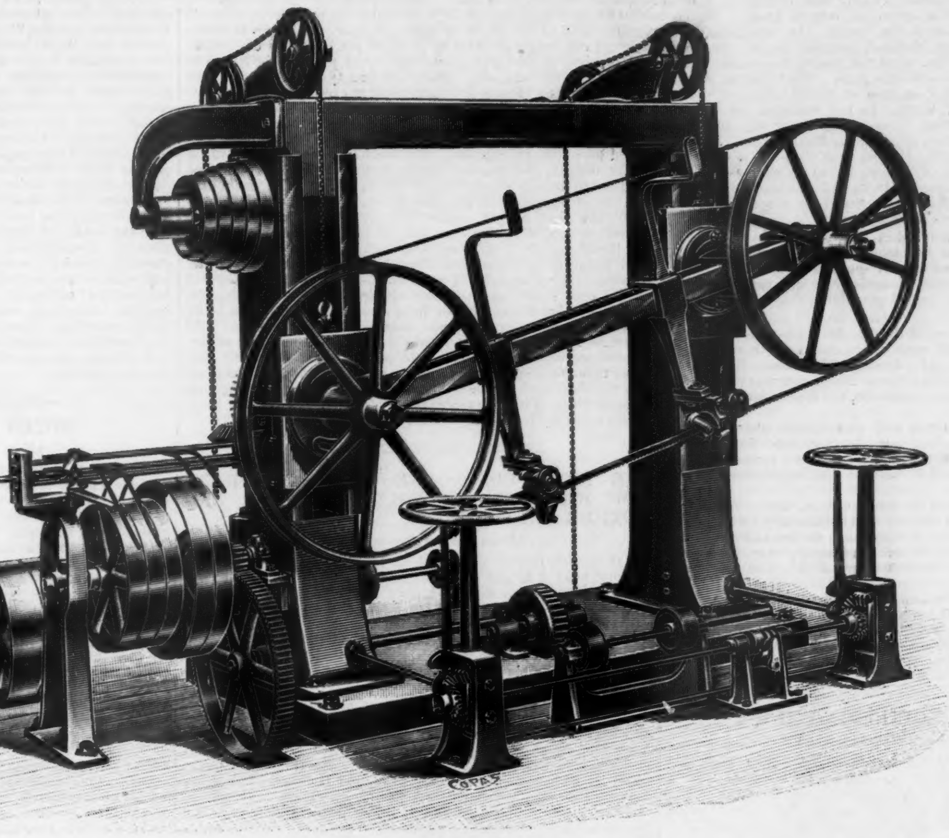
Undoubtedly something between these two possible developments of energy per pound of gasoline was given. Within certain limits, therefore, it appears that, with the type of engine used in this machine, resistance to propulsion is not an important factor in economy of fuel, as with more work to be done the fuel developes higher duty. Whether this be an argument for or against the engine is a question treated in another part of this report.

Economics.—The economics of the motocycle is a broad subject, and it does not come within the province of this report to do more than touch on economy of consumption and use of gasoline as fuel. A disregard of fuel consumption under the plea that gasoline is a cheap commodity must be considered unwarranted, when it is realised that a capitalisation of an extra amount expended for gasoline would justify a higher price to be paid for a vehicle more efficient in transferring the energy of the gasoline into propelling energy. An important factor in economy of fuel consumption is involved in control by changing the mixture of air and gasoline. It is evident that, given two vehicles possessing equal merit as regards their control, then the one accomplishing certain results with the least cost of operation represents a lower annual cost of operation than the other, and consequently a justifiable higher first cost. Aside from the actual cost of an increased amount of fuel, the disadvantages of handling or storing it is a matter for consideration, particularly if the more volatile petroleum products are used and the question of underwriters' restrictions is considered.

Use of gasoline.—For the following notes bearing on the use of gasoline we are indebted to Samuel Rodman, jun., explosive expert:—Gasoline is the lightest volatile produce commonly obtained from the distillation of crude petroleum. Specific gravity, ·660 to ·690; boiling point, 158 deg. Fah. to 194 deg. Fah. Naphtha is a lower product. Specific gravity, ·690 to ·700; boiling point, 175 deg. Fah. to 230 deg. Fah. Benzine is a still lower product. Specific gravity, ·730 to ·760; boiling point, 248 deg. Fah. to 302 deg. Fah. Petroleum, generally known as kerosene, is graded by flashing tests which run from 110 deg. Fah. to 265 deg. Fah. and over. Its specific gravity varies from about ·82 to about ·86. All volatilise more or less readily, giving off hydrocarbon vapours, which, uniting with air, form explosive mixtures. Careful investigations have been made with a view of regulating the storage and transportation of hydrocarbon oils. In the case of petroleum it has been determined

LOG BAND SAW FOR SWEEP AND BEVEL WORK

MESSRS. A. RANSOME AND CO., CHELSEA, ENGINEERS



that one volume of petroleum vapour renders 380 volumes of air explosive and 1150 volumes inflammable. A red-hot piece of metal or coal or a spark from steel or flint will not ignite an explosive atmosphere of petroleum vapour, but white-hot metal, flame, or electric spark will readily do so. Naphtha exposed to an atmospheric pressure of 30in., at a temperature of 70 deg. Fah., evaporates at the rate of about 0·09 lb. per square foot per hour. Many accidents are recorded from explosions of hydrocarbon vapours mixed with air. In the majority of those that have come under notice, vapours of hydrocarbons have escaped into the air through some leak in the receptacle or pipe holding them, and explosion has occurred on the approach of a naked flame.

In closing this report we desire to acknowledge valuable services and assistance in conducting the tests as follows:—Our thanks are due to Messrs. Samuel Rodman and C. L. Brown for assistance at the tests and subsequently in figuring out results. For special wheels prepared for test we are indebted to the Hartford Rubber Company for those having pneumatic tires, to the Rubber Tire Wheel Company for those having solid rubber tires, and to the Staver and Abbott Company, of Chicago, for those having steel tires. Through the courtesy of Mr. Frem, Messrs. Fairbanks, Morse and Co. furnished delicate scales for use in dynamometer work, and Mr. Ludlow, of the Crosby Steam Gauge and Valve Company, furnished the speed indicators used.

JOHN P. BARRETT, Chairman of Committee.

RANSOME'S LOG BAND SAW WITH CANTING PULLEYS.

THIS machine, illustrated by the above engraving, was designed and constructed for Messrs. Harland and Wolff, of Belfast, by Messrs. A. Ransome and Co., Chelsea, for carrying out special work that is costly and tedious to do by any other means. It is specially arranged for cutting curves and bevels in logs and spars of any length up to 60ft., and of any diameter up to 36in. The machine, when its pulleys are in their normal position, is of the horizontal type of band saw, but to effect the necessary sweep and bevel cutting, each pulley can be lifted or lowered independently of the other, whether the machine is actually in the cut or not. Thus the blade will follow any curves or bevels that may be marked on both sides of the log. The saw pulleys are 48in. in diameter, and are arranged to rise and fall by hand wheels on either side of the machine, thus bringing them under perfect control of the attendants, one of whom would be stationed at each hand wheel to follow the necessary sweeps, bevels, and curves required at either side of the piece being sawn. The slide carrying these band pulleys is counterbalanced by suitable weights, thus making the motion easy and rapid.

Practically, the whole of the machine being above the floor line, but little expense is required in the way of foundation. The travelling table is 60ft. long, this length covering spars and logs of the maximum ordinary lengths used in shipbuilding. It is made up of malleable iron plates ½in. thick. These plates are carried on three longitudinal H beams, two of which run on suitable rollers, the underside of the third or centre one being fitted with rack. As a rule, the pieces lie on the table themselves without any fixing, being held in position by their own weight, but for spars and logs of uneven thickness, a series of dog-screws are required to prevent such pieces from moving while in operation. The table is not shown in our engraving. It is carried in the usual way, and is moved by the cog-wheel which can be seen in the centre of the space between the two standards. The feed motion is arranged with five different rates of speed. The saw guides are specially made so that the blade can be canted in the necessary direction, according to whether the cut is leading down or up in the sweep or curve. The weight of this machine is 13 tons. The average indicated power required is about 15-horses. The pulleys driving it make 400 revolutions per minute.

PRESENT STRENGTH OF THE NEW UNITED STATES NAVY.

IN August, 1882, Congress approved an Act to complete the double-turreted monitors and for the construction of a 6000-ton protected cruiser. This Act was so vague that it was not until March 2nd, 1883, that Congress appropriated 1,300,000 dols. to begin the construction of four ships. With these ships the new navy was born, and each year since it has been added to until we now have a naval list of nearly a hundred ships in commission, ready to be commissioned, or building.

Among this number are five double-turreted and thirteen single-turreted monitors, six battleships, one coast defence ship, twenty-five cruisers, one dynamite cruiser, one harbour defence ram, one naval school ship, eight gunboats, six torpedo boats—including one ram and one submarine—one survey and one despatch boat, besides many vessels of smaller build and efficiency, serving in different capacities where they are respectively stationed.

Of the enumerated vessels, the six battleships, eighteen cruisers, six gunboats, five torpedo and one despatch boat, the naval school ship Bancroft, the harbour defence ram Katahdin, the dynamite cruiser Vesuvius, and the coast defence ship Monterey are built of steel.

The eighteen armoured monitors, one cruiser, two gunboats, the survey steamer Ranger, and the ram Alarm are of iron, while the old wooden ships include six cruisers and the store ship Mohican.

The ships are divided into four classes: (1) Armoured, including the battleships, monitors, cruisers, and coast defence ships; (2) unarmoured protected vessels, including cruisers, gunboats and despatch boats; (3) unarmoured ships of iron; (4) wood, comprising vessels of the old navy.

The first-class battleships Massachusetts and Oregon are each of 10,231 tons displacement, 9000 indicated horse-power, developing a speed of 16 knots to the former, and 16·8 knots to the latter. In armament these two ships are precisely the same, carrying four 13in., eight 8in., and four 6in. breech-loading rifles, sixteen 6-pounder, and four 1-pounder quick-fire, and four Maxim guns. The second-class battleship Texas has a speed of 17 knots, with 8600 indicated horse-power, and a displacement of 6300 tons. She mounts two 12in. and six 6in. breech-loading rifles, twelve 6-pounder, four 1-pounder quick-firing, and four Maxim guns.

Of the protected cruisers, the Chicago has a displacement of 4500 tons, a speed of 15 knots and 5000 indicated horse-power. Her battery contains four 8in., eight 6in., and two 5in. breech-loading rifles, four quick-fire, and eight Maxim guns. The Baltimore has a displacement of 4413 tons and indicated speed of 19·2 knots furnished by engines of 10,750 indicated horse-power. Her battery has two 8in. and six 6in. breech-loading rifles, four 6-pounders, two 1-pounder quick fire, and seven Maxim guns. The Philadelphia, with the same displacement as the Baltimore of 4413 tons, has made 19 knots with 10,500 indicated horse-power. She mounts twelve 6in. breech-loading rifles, four 6-pounder, four 1-pounder quick-fire, and seven Maxim guns. The San Francisco has displacement of 4083 tons, a speed of 19·5 knots, and engines of 10,500 indicated horse-power. She carries twelve 6in. breech-loading rifles, four 6-pounder quick-fire, and seven Maxim guns.

The Atlanta and Boston have each a displacement of 3189 tons. The Atlanta has a speed of 15·4 knots, attained by 3511 indicated horse-power; the Boston requiring 3780 indicated horse-power to attain a speed of 15 knots. On both of these ships the batteries are the same, consisting of two 8in., six 6in. breech-loading rifles, six quick-fire, and six Maxim guns.

Of the unprotected cruisers, the Minneapolis has developed a speed of 23·073 knots, with engines of 21,000 indicated horse-power. Her displacement is 7475 tons, she carries one 8in. and two 6in. breech-loading rifles, eight 4in. rapid-fire, twelve 6-pounders, eight 1-pounder quick-fire, and four Maxim guns.

The Cincinnati and Raleigh are Government productions, having been built, the former at the Brooklyn Navy yard and the latter at the Norfolk yard. They are of 3183 tons displacement, 10,000 indicated horse-power, and a speed of 19 knots each. The Cincinnati carries one 6in. and ten 4in. breech-loading rifles, two 6-pounders, two 3-pounder quick-fire, and four Maxim guns. Mounted on the Raleigh are one 6in. breech-loading rifle, ten 5in. rapid-fire, eight 6-pounder, four 1-pounder quick-fire, and two Maxim guns.

The gunboat Yorktown, one of the first four ships authorised, has a displacement of 1700 tons, an indicated horse-power of 3400, developes a speed of 16 knots, mounts a battery of six 6in. breech-loading rifles, four 6-pounder quick fire, and five Maxim guns.

After building and commissioning the next two gunboats Machias and Castine, they were found to be too topheavy in a seaway. To rectify this defect it was decided to lengthen them. Accordingly the two vessels were cut in two amidships and rebuilt, thus righting the blunder originally made. In these two vessels there is but one point of difference, the Machias having a speed of 14·5 knots, from 1600 indicated horse-power engines, with a displacement of 1050 tons, where the Castine makes but 14 knots with the same horse-power and displacement. In armament the two vessels each carry eight 4in. rapid-fire, four 6-pounder, two 1-pounder quick-fire, and two Maxim guns. The Petrel is of 890 tons displacement, has a speed of 13 knots, engines of 1300 indicated horse-power, a battery of four 6in. breech-loading rifles, three 3-pounder quick-fire, and four Maxim guns.

The coast defence double-turreted ship Monterey has a displacement of 4048 tons, a speed of 16 knots, engines of 5400 indicated horse-power.

Mounted in her two turrets are two 12in. and two 10in. breech-loading rifles, with a lighter battery of six 6-pounder, four 1-pounder quick-fire, and four Maxim guns, mounted on the superstructure and in the fighting top.

The harbour defence ram Katahdin carries but a light secondary battery of four 6-pounder quick-fire guns. She has a displacement of 2050 tons, a speed of 17 knots, and engines of 4800 indicated horse-power. The dynamite cruiser Vesuvius has a displacement of 725 tons, a speed of 21 knots, and engines of 3200 indicated horse-power. She was designed to throw 600lb. charges of dynamite from her 15in. pneumatic guns, which are supplemented by three 3-pounder rapid-fire guns. The torpedo boat Cushing is of 116 tons displacement, has engines of 2500 indicated horse-power, and a speed of 22·5 knots per hour.

Among the vessels now building the Iowa stands first with a displacement of 10,286 tons, indicated horse-power of 11,000, and a contract speed of 16·5 knots. When ready for active service the Iowa will carry a battery of four 12in. and eight 8in. breech-loading rifles, six 4in. rapid-fire guns, twenty 6-pounder, six 1-pounder quick-fire, and two Maxim guns. The Indiana, now nearing completion, is one of the three heaviest vessels which at present are on the naval list. She has engines of 9000 indicated horse-power, a speed of 16 knots, and a displacement of 10,231 tons. In armament and construction she is the counterpart in every particular of her sister ship Massachusetts. Her battery will have four 13in., eight 8in., and four 6in. breech-loading rifles, sixteen 6-pounder, six 1-pounder quick-fire, and four Maxim guns. The second-class battleship Maine has a displacement of 6648 tons, a speed of over 17·7 knots, and engines of more than 9000 indicated horse-power. She has four 10in. and six 6in. breech-loading rifles, with a secondary battery of twelve 6-pounder, four 1-pounder quick-fire, and four Maxim guns. The cruiser Brooklyn, now on the stocks, is an improved model of the New York. She is to have a speed according to contract of 21 knots, to be of 16,900 indicated horse-power, and have a displacement of 9250 tons. Her batteries will be eight 8in. breech-loading rifles, twelve 5in. rapid-fire, twelve 6-pounder and four 1-pounder quick-fire, four Maxim guns, and two light or field pieces.

The New York has a speed of 21 knots, triple expansion engines of 16,000 collective indicated horse-power, and a displacement of 8150 tons. Her armament consists of six 8in. breech-loading rifles, twelve 4in. rapid-fire, eight 6-pounder, four 1-pounder quick-fire, and four Maxim guns. The Newark has a displacement of 4083 tons, an indicated horse-power of 8500, driving her at the called-for speed of 19 knots. In armament she is inferior to the Chicago, carrying twelve 6in. breech-loading rifles, four 6-pounders, quick-fire, and nine Maxim guns. The Charleston has a displacement of 3730 tons, engines of 7500 indicated horse-power at a contract speed of 17 knots. Mounting batteries of two 8in. and eight 6in. breech-loading rifles, four 6-pounder, two 3-pounder quick-fire, and eight Maxim guns.

In the Marblehead and Montgomery the Government contract calls for two ships of the same dimensions and armament, with displacements of 2000 tons, engines of 5400 indicated horse-power, driving the ships at a speed of 18·3 knots. The batteries of these two ships comprise two 6in. breech-loading rifles, four 4in. rapid-fire, four 6-pounder, three 3-pounder quick-fire, and two Maxim guns.

The Concord and Bennington are similar ships in all but their displacement, the latter being 1750 to the former's 1700 tons displacement, with indicated horse-powers of 3400 and called-for speed of 17 knots. In armament these two ships are identical, mounting six 6in. breech-loading rifles, four 6-pounder quick-fire, and five Maxim guns.

The Columbia has a displacement of 7475 tons, engines of 21,000 indicated horse-power, and a speed of over 22 knots. She is probably the fastest cruiser in the world. In armament the Columbia and Minneapolis are identical, carrying one 8in., two 6in. breech-loading rifles, eight 4in. rapid-fire, twelve 6-pounder, eight 1-pounder quick fire, and two Maxim guns. The Olympia, with a displacement of 5500 tons and engines of 13,500 indicated horse-power, has a speed of 20·2 knots. In her batteries she carries four 8in. breech-loading rifles, sixteen 5in. rapid-fire, fourteen 6-pounder, six 3-pounder quick-fire and four Maxim guns. Among the first of the new ships, the Detroit was built on a contract calling for a displacement of 2000 tons, driven by engines of 5400 indicated horse-power at a speed of 18 knots. She mounts two 6in. breech-loading rifles, four 3½in. rapid-fire, four 6-pounders, two 1-pounder quick-fire, and two Maxim guns.

Among the vessels commissioned in 1894 was the naval training ship Bancroft, of 838 tons displacement, with engines of 1300 indicated horse-power, developing a speed of 13·5 knots. For practice and drill her batteries comprise four 4in. rapid-fire, two 6-pounder, two 3-pounder, one 1-pounder quick-fire, and two Maxim guns.

The Dolphin, which was one of the first four ships contracted for of the new navy, is of 1485 tons displacement, with engines of 2300 indicated horse-power and a speed of 15·5 knots. She is now the despatch boat of the United States Navy, carrying but a light armament, comprising two 4in. rapid-fire, two 6-pounder quick-fire, and six Maxim guns.

Of the monitors, the Puritan, with two turrets mounting four 10½in. breech-loading rifles, four quick-fire and eight Maxim guns, with a displacement of 6060 tons and indicated horse-power of 3700, attaining a low speed of 13 knots, is the largest and heaviest of her type.

The Amphitrite, another of the monitor class, carries four 10½in. breech-loading rifles in two turrets, with a secondary battery comprising six quick-fire and four Maxim guns; she has a displacement of 3990 tons, and engines of 1600 indicated horse-power, developing a 12-knot speed, and is one of three ships of this class that stand next to the Puritan.

The torpedo boats Ericsson and the one now known as No. 2 are greatly different in size, the former having 750 tons displacement against No. 2's 120. These little fliers have a speed of 23 knots in the Ericsson and 24 in No. 2.—*Scientific American.*

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Shunting by electricity.—At the terminals of the New York and Brooklyn Bridge Cable Railway experiments are being made with electric power for switching or shunting the trains from the arrival to the departure track, in order to replace the present steam switching locomotives. The trains are made up of four cars, each mounted on a pair of four-wheel trucks or "bogies," and each weighing 20 tons empty. The train stops at the arrival platform, and while discharging passengers the steam engine is coupled up, then hauls the train out beyond the station, and pushes it back again on to the departure track. Under the new system one car of each train will be fitted with four 50-horse power electric motors, one on each axle, which will furnish the power for moving the train out from the arrival platform and back to the departure platform. There is at present an overhead wire from which current is taken for lighting the cars, and this will be utilised for the more powerful current required for switching, the motor car having two collectors on the roof, each consisting of a contact roller, with a long arm on each side to allow for the lateral movement of the car as it passes over the curves. The contact roller and arms are on top of a jointed diamond frame, which can be extended to press the roller against the wire or depressed to bring it out of contact. The car will carry passengers, no change being made in the interior. The motors are thoroughly enclosed and the armatures are wound on the Eickemeyer system. At each end of the car is a controller, mounted on the platform, and two or four of the motors can be put in service as desired. The motors can also be utilised in assisting heavy trains up the 1 in 35 grades, and the motor cars can run across the bridge by their own power from 1 a.m. to 5 a.m., when the cable plant is stopped for examination, the steam engines being now used.

A heavy "Bank" locomotive.—On the south-west system of the Pennsylvania Railroad, near Madison, is the Madison Hill incline, rising 413ft. in 7012ft., the grade being about 1 in 20. This was built in 1841, and from 1848 to 1868 it was operated on the rack and cog-wheel system. It is said to be the steepest grade in the world on which regular through main line traffic is operated. The adhesion engine introduced in 1868 had ten driving wheels, 44in. diameter; cylinders, 20in. by 24in., and weighed 57 tons. In 1886, one pair of wheels was taken out to reduce the wheel-base to 16ft., and enable the engine to pass over the curves in the yard at Madison. It had a hauling capacity of 120 tons, and was equipped with an air-brake using air in the steam cylinders in descending the grade. This engine, after twenty-seven years' service, has been replaced by a heavier bank or pusher engine, used for helping trains up the grade. It is a tank engine, carrying about 2000 gallons of water in side tanks, and coal in a bunker behind the cab. It has cylinders 22in. by 28in., four pair of wheels—all drivers—50in. diameter, and weighs 70 tons on a wheel-base of 15½ft. The boiler has a Belpaire fire-box, and carries a steam pressure of 150 lb. per square inch. The Westinghouse-American driving-wheel brake is fitted to all the wheels, and there are also hand-screw brakes for emergency use, and the Le Chatelier brake for use in descending the grade. Sand is fed to the rail by an air jet, and compressed air is also used to ring the bell. On a wet wintry day, with the track in bad condition, the engine has pushed a train load of 150 tons up the grade by itself. In regular service, however, it will be used as an auxiliary to the regular engines.

An ocean-going tug.—A powerful sea-going tug boat of unusual size has recently been built for the Philadelphia and Reading Coal Co. for towing the great coal barges and hulks—made from dismantled steamers and sailing ships—between the different coal ports. The vessel is 171ft. long, 29ft. beam, 31ft. wide over the guards, and 18ft. 6in. depth of hold. The bow is heavily built and braced for breaking through the ice. The screw propeller is driven by a triple-expansion marine engine, with cylinders 18in., 28in., and 45in diameter, supplied with steam by marine return tubular boilers carrying 160 lb. steam pressure. The water tanks in the fore and aft compartments have a capacity of 31,000 gallons, and the coal bunkers hold 280 tons of fuel, the consumption being about 20 tons per day. The crew and firemen have accommodation in the forecastle, and a long deck-house has the engineers' and officers' quarters, a roomy enclosed chart-house and wheel-house being on top of the fore end of the deck-house. The two masts are fore and aft rigged, and carry sail enough to give steerage way in case of accident. The vessel has a sea speed of 13 knots, running light, and can tow four barges loaded with 1500 tons of coal each. Electric lighting is provided throughout, two dynamos being fitted, and there is a search-light of 10,000-candle power. The tow lines are coupled to a 1½in. steel wire cable wound on the drum of a steam towing engine, any sudden strain beyond a certain limit causing the cable to unwind, while the drum winds it back again as soon as the strain slackens. In the stern is a steam capstan, and in the bow a steam and hand windlass for the 12-ton anchor. Combination steam and hand steering engines are fitted, together with Hand's patent binnacle and compass, so arranged that all local deviations can be adjusted by compensation compasses. Powerful wrecking and fire pumps are included in the equipment, and the living quarters are heated by steam.

Large boilers.—The Queen-lane pumping station of the Philadelphia Water Works has to pump 80,000,000 gallons per twenty-four hours to a height of 250ft. This requires 3500 net horse-power, and with an evaporation of 34½ lb. of water per H.P. per hour would require a total of 120,750 lb. of water per hour. The type of boiler designed will evaporate 5000 lb. of water per hour into dry steam, with economy of fuel and labour, and could probably be forced to 8000 lb. with fair economy. There are twenty-four boilers at this station, and they furnish dry steam with not over 1 or 1½ per cent. of water. There are four batteries of six boilers, each boiler having a separate flue connecting to the main flue, which runs under the boiler room, the smoke flue of each boiler being controlled by a separate damper. The contract price was £16,940 for boilers, fittings, and non-conducting clothing. The steel used has an ultimate tensile strength of 50,000 lb. to 60,000 lb. per square inch, an elongation of 25 per cent. in 8in., and a reduction in area of not less than 50 per cent. Test pieces were bent 180 degrees without a sign of fracture on the outside. The shell plates are ⅞in. thick and the heads and combustion chambers ⅝in. thick. Each boiler is 8½ft. diameter, 20ft. long, with ninety tubes 4in. diameter, twelve staybolts 2⅝in. diameter—having nuts inside and outside each head—and two Fox corrugated flues 3½ft. diameter. Each boiler head was flanged in a machine at one stroke. The riveting was done by hydraulic riveters. Each boiler has 1200 square feet of heating surface, or 8·4 square feet per horse-power. The boilers rest on cast iron saddles on brick walls, a 48in. flue under them keeping the waste products of combustion in contact with the shell until drawn out through the damper opening into the main flue. With an evaporation of 5000 lb. of water per hour, 34½ lb. is the equivalent for 1-horse power.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

GREAT satisfaction is expressed at the improvement compared with last year of 33 per cent. in the value of the iron and steel exports of all kinds during February, made known this week. It is regarded hereabouts as a good indication of steady and substantial trade revival. Pig and puddled iron has gone up 118 per cent., bar and angle 23 per cent., railroad 135 per cent., wire 49 per cent., cast and wrought iron 46 per cent., old iron 122 per cent., unwrought steel 67 per cent., galvanised sheets 91 per cent., and unwrought tin 76 per cent. In pig and puddled iron the increased exports have been chiefly to Germany, Holland, Belgium, and the United States. The bulk of the increased shipments of railroad material has been to the British East Indies, Australasia, Argentine, Brazil, the United States, and Sweden. For cast and wrought iron the increased demand has come from Australasia, the West Indies, South Africa, Brazil, and Holland. The extra consignments of unwrought steel have been chiefly to Germany, the East Indies, and to markets of minor importance. The only decreases have been hoops and sheets 7 per cent., and tin-plates 45 per cent. As to the latter, not much trade is done from this district to America, though the district tin-plate firms do a little, but Wales is, of course, the chief sufferer. Hoop for America is, however, decidedly a Staffordshire trade, and the decrease therefore affects local interests; and so does the falling away in "sheets," which are plain ungalvanised sheets, used for tinning purposes out there. However, these unsatisfactory items are far more than counterbalanced by the numerous departments in which trade has extended, and the returns have, therefore, created a very favourable and cheering impression in South Staffordshire, as they doubtless have also in every other part of the kingdom except Wales.

With regard more particularly to galvanised sheets, which are one of the staple trades of Birmingham and the district, it may be mentioned that in addition to the 91 per cent. increase in value above mentioned, there is an improvement of about 75 per cent. in quantity. The total quantity shipped rose from 12,416 tons in February, 1895, to 21,788 tons last month; and from £134,299 to £256,978. The following are the chief cases of progress:—Australasia, from 2556 tons to 5241 tons, and from £32,638 to £68,373; India, from 3877 tons to 4859 tons, and from £38,354 to £52,604; South Africa, from 1085 tons to 2492 tons, and from £11,307 to £28,481; the Argentine Republic, from 712 to 2081 tons, and from £6765 to £22,684. We have done more also with Europe, the West Indies, Chili, and Brazil. Similarly gratifying evidences of trade revival are available also as regards the first two months of this year, compared with the corresponding period of 1895. The total quantity of galvanised sheet exports for the two months has improved from 26,068 tons last year to 40,810 tons this year, and the value from £281,816 to £477,217. The income from our Antipodean trade expanded in value from £69,498 to £120,764; Indian from £71,377 to £84,607; and South African from £28,607 to £79,106. The improvement in tonnage for the two months period was as follows:—South Africa, 2769 tons to 7007 tons; India, from 7111 tons to 7830 tons; and Australasia, from 2556 tons to 5241 tons. It has been quite three or four years since the galvanised sheet firms of this district were so busy as at present.

Marked bars this afternoon were quoted £7 to £7 12s. 6d.; merchant bars, £6 to £6 5s.; and common, £5 5s. to £5 10s. Black sheets are quoted £6 15s. for doubles and £8 for lattens. Angles are £5 15s.; stamping sheets, £9 10s.; best thin sheets, £11; hoops and thin strip, £6 7s. 6d.; tube strip, £5 10s.; nail rods, £6 10s. The quotations for steel are very firm at £4 10s. for Bessemer blooms and billets; £5 12s. 6d. to £5 17s. 6d. for angles and boiler plates; £5 15s. to £6 for bars; and £7 5s. to £7 10s. for sheets. Girders and angles of basic steel are quoted £5 10s., and boiler plates £6 5s. Galvanised sheets of 24 gauge are quoted £10 5s. to £10 7s. 6d. f.o.b. Liverpool.

Pig iron is very strong, and prices are firmly maintained at cold-blast 90s.; South Staffordshire all-mine, 55s. to 57s. 6d.; part-mine, 42s. 6d., and 36s. for cinder pig. Northampton forge is 41s. to 42s. 6d.; North Staffordshire and Derbyshire, 42s. to 43s.; and Lincolns, 44s. to 45s.

Muntz's Metal Company has made a profit on the past year's transactions of £6767 15s. This sum, added to the balance of £4450 7s. 9d., brought forward from the previous year's account, gives a disposable surplus of £11,218 2s. 9d. To this amount the directors propose to add £4000 from the reserve fund, which was created for the purpose of equalising dividends, making a total of £15,218 2s. 9d. An interim dividend at the rate of 5 per cent. per annum was paid on the preference shares to the 30th June last, which disposed of £4467 7s. 6d. It is now proposed to pay a dividend on the preference shares at the rate of 5 per cent. per annum for the half-year ended December 31st last, and a further dividend of 7½ per cent. on the ordinary shares, which will absorb £9840 2s. 6d., leaving a balance of £910 12s. 9d. to be carried forward to the next account. The stock of copper on hand is valued at £113,000, and the machinery and tools at £16,590. The directors who retire are Mr. P. A. Muntz, M.P., and Sir Henry Wiggin, Bart., who offer themselves for re-election.

The proposed combination of employers and employed in the Birmingham brass trades is rapidly becoming an accomplished fact. An important meeting of masters and men engaged in the metal-working trades, held at the Town Hall, Birmingham, on Tuesday, passed the following resolution:—"That having considered the proposed alliance in all its bearings, this meeting agrees to confirm its provisions by signature on both sides, and to establish a Wages Board forthwith; but conditionally that the provisions of the alliance shall not be enforced on either side until both parties have agreed that the combination is sufficiently strong to prevent underselling, and to place the trade on a profitable basis. Pending such decision selling prices shall not be raised, and the Wages Board shall only exist for the purpose of friendly consultation. Whenever an advance of prices is declared, it shall be with the consent of the Wages Board, and shall carry with it the bonus to workpeople provided for in the terms of the alliance." It was also resolved "That the chairman and the secretary of the Employers' Association, and Mr. W. J. Davis, on behalf of the Cased Tube Association, and Mr. S. Lakin on behalf of the Gasworkers' Union, and two operatives to be chosen by the meeting on behalf of those operatives who may not at present have joined either of the above associations, be instructed to sign the alliance on behalf of the employers and employés who have so far given in their adhesion to the scheme, subject to the provisions contained in the resolution just recorded." The gathering also decided "That this meeting of employers and employed, being parties to the alliance just signed, pledges itself to do its utmost by every lawful means to bring into the arrangement every employer and workman in the trade." This is one of the most important movements that has taken place in the Birmingham brass trade for many years.

In the South Staffordshire district a considerable record of new work has been booked during the past week. The bridge and girder makers have received further contracts, and several other important orders are under consideration. The heavy ironfounders have secured orders for some very large rolls, and inquiries are to hand for others from ship-plate, &c., works owners who will tender for the new ships to be built for the Admiralty. Rolling plant for steel works in Scotland and the North of England is inquired for as breakages, &c., are frequent from the high rate of production that is going on.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—I recently referred in my notes to the probability of some weakening in prices by iron being thrown on the hands of makers, owing to buyers not taking their full deliveries on account of contracts, and this anticipation is already, I find, to some extent being realised. It is now evident that the heavy buying going on recently has in some quarters been considerably in excess of requirements; users, in the expectation of higher prices, have bought much beyond their usual quantities, whilst merchants in not a few instances have contracted for more iron than they can take. The result is that makers, although heavily sold, are here and there finding a difficulty in getting their customers to take their deliveries according to contract, and with iron accumulating on their hands they are not quite so strong in holding out for recent maximum rates, whilst some merchants who are overbought are offering at under current rates to secure orders. This necessarily tends for the time being to weaken the market, but there is a continued sound, healthy condition of trade generally, with a confident tone as regards the future, and the very favourable Board of Trade returns just issued are a further satisfactory evidence of the well-established improvement.

Only a quiet tone was reported generally on Tuesday's Manchester iron market, with, if anything, rather less firmness in prices. For pig iron inquiries were mostly limited to small quantities, and makers in some instances were prepared to give way slightly upon recent full quotations, whilst merchants were here and there low sellers. Local makers are fully maintaining their list rates on the basis of 46s. 6d., less 2½, for No. 3 foundry, delivered equal to Manchester. Lincolnshire iron, however, is perhaps easier, and it is only in exceptional cases where more than 42s. is now being got for forge, and 44s. for foundry, although 6d. above these figures is still quoted, whilst for Derbyshire foundry the top figure is 47s. net cash, delivered Manchester, with some sellers at 6d. to 1s. less. With regard to outside brands, Middlesbrough is about 3d. easier, 46s. 10d. to 47s. 1d. net cash being about the average figures for good-named foundry qualities, delivered Manchester stations, and 45s. 9d. Manchester Docks; with Eglinton, 47s. 6d. net prompt cash, delivered Lancashire ports, and 49s. 9d. to 50s. delivered Dock Quays, Manchester.

In the finished iron trade there is a moderate business stirring, but the recent advance is not being got in all cases. Lancashire bars could now be bought at £5 10s. to £5 12s. 6d. delivered Manchester, or for export. Sheets remain at £7 10s. to £7 12s. 6d.; and the Association list rates for hoops at £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

A strong position is maintained in the steel trade. Hematites are firm at fully late rates, 57s. 6d., less 2½, being the minimum for good foundry qualities, and 58s. 6d. for some special brands, whilst good steel billets now average £4 10s. net cash, and boiler plates are not quoted under £6 7s. 6d. to £6 10s. per ton, delivered in this district.

In the metal market the check to further buying which followed upon the advance in prices last week has been additionally emphasised by the downward tendency in raw material, which encourages anticipations on the part of buyers of a return to recent rates. Specifications, on account of orders already booked, are keeping makers fairly busy, but very little new business is stirring, consumers holding back for lower prices where they are not absolutely compelled to buy.

The usual monthly returns issued by the engineering trades unions fully bear out the satisfactory reports I have previously given from representatives of engineering firms throughout the district as to the continued steady improvement in trade, and the encouraging outlook for the future. The employment returns show a less proportion of out-of-work members on the books of the societies than has been the case for five or six years past. The Amalgamated Society of Engineers, which last month had 5 per cent., has now very little above 3 per cent. of its total membership on the unemployed list, and in the Manchester district there has been a similar decrease, the number of out-of-work members being now only about 2 per cent. of the membership, and the local secretary is receiving an exceptional number of inquiries for smiths, pattern-makers, and in fact, for all classes of workmen, from firms in the district, the position as regards employment being better than it has been for several years past. In the Steam Engine Makers' Society the returns show an unemployed list of only one and a-half per cent. which represents a substantial reduction on last month's returns. The reports from the various districts with regard to the state of trade indicate a continued increase of activity in practically all branches, with heavy stationary engine builders especially well engaged, and in marine centres, with one or two exceptions, an improvement is now making itself felt as regards the weight of work coming forward.

The ever-increasing network of overhead telephone wires in nearly every business centre of any importance is imposing conditions with regard to the construction of fire-escape appliances, which has necessitated a considerable modification of the ordinary telescopic ladder escapes, which in many towns it would now be scarcely practicable to convey along the streets in an upright position. Some months ago I briefly noticed an exhibition by Messrs. Wm. Rose and Co., of Manchester, of their improved types of fire escapes, and during the present week they have again been showing in the large yard of the Albert-street Police-station further improvements that have since been introduced, so as to afford public authorities who may have in contemplation the re-organisation of their life-saving and fire-extinguishing appliances an opportunity of testing the latest designs. Amongst the appliances exhibited were one of Messrs. Rose's combined hose tenders and escapes, containing several improvements on the one previously exhibited. In order to demonstrate as plainly as possible the use of this machine, it was shown with the tender fully equipped with the requisite hose, stand, and branch pipes, &c., manned by the firm's private brigade, and drawn by a pair of horses. A special feature in this machine is the accessibility of the tender for the purpose of taking out the fire-extinguishing appliances, without having to detach the escape, in case the latter is not required to be made use of at a fire. Another escape of novel construction was one of their patent Metropolitan escapes, the ladders of which are made in three sections to extend to 72ft., and so constructed that three men can readily raise the ladders from the horizontal to the vertical position, and at the same time fully extend the ladders according to the height required. A specimen of the latest type of 50ft. patent sliding carriage escapes, as supplied by Messrs. Rose and Co. to the London Fire Brigade, was also exhibited; this escape, like the others, containing several improvements. There were also on exhibition two of the firm's well-known patent "Kingston" escapes, one of these being convertible for horse draught, or for being pushed by men, besides being provided with geared raising motion, the other being the ordinary "Kingston" escape with quick-action raising motion; and one of their patent curricle escapes, which, since their introduction last year, have found considerable favour, particularly with rural fire brigades, the under carriage or van having stowing capacity for a large quantity of hose and other appliances, and being easy of access, no matter in what position the ladders may be. In the fixing of the ladder rounds or treads of the first three types of escapes referred to above, Messrs. Rose and Company have adopted a device for which they claim several advantages. This device consists in attaching light metal sockets to each end, by means of which the treads are secured to the ladder sides, each socket having a rib or web on the under side, connecting it to a flange which is let into the wood. This mode of attachment enables each tread to be easily taken out of the ladder for renewal when required without having to take the ladder to pieces, besides giving great support, and therefore additional strength, to the treads, and lastly making the ladders very rigid, an important factor in the construction of fire-escapes.

At the ordinary monthly meeting of the Manchester Geological Society, held on Tuesday, a short contribution by Messrs. W. F. Holroyd and J. Barnes, was read with reference to the stratified beds of clay found in many of the valleys of Scotland, which frequently contained curiously-shaped concretions that were known as "fairy stones." These clay deposits varied in thickness from 20ft. to 90ft., and were found very regularly deposited in valleys through which the rivers had to flow. The composition of the clay seemed to be a kind of marl, containing silicate of alumina, carbonate of lime, and carbonate of iron, with probably some magnesia. These deposits extended over considerable areas, and "fairy stones" had been found resembling masses of clay twisted around each other in all conceivable forms, the origin of which had been a puzzle to geologists, but Messrs. Holroyd and Barnes attributed their presence to chemical action following upon the decay of rootlets of trees, which had grown on the surface. Mr. M. Stirrup, F.G.S., also read a contribution from Mr. G. H. Kinahan, M.R.I.A., in which he brought forward evidence in proof of a possible land-connection in recent geological times between Ireland and England. The usual votes of thanks were passed, and Mr. W. Saint, H.M. Inspector of Mines, remarked that Mr. Kinahan had been on the Irish Geological Survey for a number of years, and there was no one who could give more reliable information as to the geology of that country.

In the coal trade, except a slight stiffening tendency in the better descriptions of engine fuel, there is still no appreciable improvement to report, four days per week being the average that collieries in most cases are working, whilst for all qualities of round coal only a slow demand comes forward. The better descriptions of round coal have perhaps been moving off slightly better for domestic consumption; but the business doing is still only indifferent for the time of the year, and prices difficult to maintain. Common round coals suitable for steam and forge purposes, notwithstanding the restricted production—pits in many cases scarcely raising more than half their average get—remain a drug on the market, and extremely low in price, 6s. being about a full average figure for good ordinary qualities at the pit mouth. A fair inquiry is reported for engine fuel, and in some instances large users are showing an anxiety to enter into forward contracts. The demand, however, falls chiefly on the better qualities, supplies of which are not at all in excess of requirements, and for these an advance of 3d. per ton is in some cases being quoted, the average figures being now about 4s. 6d. to 5s. per ton; for common sorts, however, which are still plentiful, low prices continue to be taken, 2s. 9d. to 3s. 3d. at the pit representing the ordinary selling prices.

Depression still prevails in the shipping trade, and common steam coal, delivered at the ports on the Mersey, are still readily obtainable at 6s. 9d. to 7s. per ton.

Barrow.—There has been a steady tone throughout the week in the hematite pig iron trade, and orders are still liberally offered at 49s. net cash warrant sellers, buyers being at 48s. 11d., while makers quote 50s. to 51s. per ton for mixed Bessemer numbers, net f.o.b. There is next to no trade in forge and foundry qualities of metal, but Bessemer is in all-round consumption. Stocks have not increased during the week, and remain exactly as they stood last week at 302,419 tons. Thirty-eight furnaces are in blast, compared with 26 in the corresponding week of last year.

Iron ore is selling at 10s. for average qualities net at mines, and 12s. 6d. for best sorts. The trade is much better than it has been of late. Spanish ore is in fair demand, and is still largely used for mixing purposes, and is quoted at 12s. 9d. to 13s. per ton delivered at West Coast ports.

The steel trade is very briskly employed in all departments, and the outlook is bright, and better than it has been for many years past. Orders are largely held for heavy rails, ship plates, billets, hoops, and castings, while a better business has been done lately in tin bars. Steel sleepers are in good demand, and are being largely produced in the West Cumberland district. Prices are steady, heavy rails at £4 15s., and ship plates at £5 2s. 6d. net f.o.b.

There is nothing to report in the shipbuilding and marine engineering trades. Very great progress is being made with the work in hand, and anticipations are indulged in that important new orders will come to Barrow shortly to take the place of the orders which are rapidly approaching completion.

The coal and coke trades are more active than they have been for some time past, and it is evident that prices are moving upward in harmony with the improved demand. Deliveries are fuller, and local railway companies are benefiting by the improved trade doing.

Shipments continue to improve slightly. The exports of pig iron from West Coast ports during last week amounted to 5484 tons, and of steel to 11,046 tons, as compared with 3328 tons of pig iron and 5894 tons of steel in the corresponding week of last year, being an increase of 2156 tons of pig iron, and 5152 tons of steel. The aggregate shipments this year to date have reached 58,503 tons of pig iron and 78,088 tons of steel, as compared with 47,674 tons of pig iron and 69,008 tons of steel in the corresponding period of last year, an increase of 10,829 tons of pig iron, and 9080 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE reports from the various districts of the Yorkshire, Derbyshire, Notts, and Lincolnshire coal fields continue to indicate no improvement in the state of the market. Supplies are largely in excess of the demand, with the necessary issues of keen competition and declining values. In several instances where the pits are particularly well located for business, and the owners have secured good contracts, five to five and a-half days' work per week is the rule. In the great majority of instances nothing like that employment can be afforded, the average over the district being not more than from three to four days. There is rather less coal being brought to bank, the men complaining of having to wait a great deal—which, of course, reduces their wages. The short spell of cold weather had some slight effect on the house coal trade, but it has now entirely passed away—the demand, particularly for the London market, being less than usual at this season of the year, and the competition more acute than ever. Best Silkstones are now making 8s. to 9s. 3d.; ordinary from 6s. 9d.; Barnsley house, from 7s. 6d. to 8s. per ton; lower grades from 6s. 9d., while thin seam coal is obtainable at 6s. per ton and upwards. Some slight improvement is reported in the steam coal trade, owing no doubt to the prospect of an early opening of the Baltic ports. This is causing a good deal of coal to be dealt with in speculative account, with the usual result of depressing values. Steam coal is quoted at 6s. 9d. to 7s. 3d., and inferior sorts rule about 6d. per ton less. A good deal of coal at present is being delivered on account of railway contracts, the quotations ranging from 6s. 9d. to 7s. per ton, secondary qualities not making more than 6s. per ton. In gas coal there is rather less doing, values being from 6s. to 7s. per ton. Manufacturing fuel is in better demand, owing to the improved state of the iron industry. Supplies, however, continue to be very large; prices consequently rule low. Small nuts are obtainable from 4s. 6d. to 5s. 6d. per ton, screened slack from 3s. 6d., pit slack from 2s. 6d., and smudge from 1s. per ton. The coke trade is considerably better, and more ovens are being built to meet the demand at Cadeby and elsewhere. Prices rule at 8s. to 10s. per ton. There are disputes at several of the district collieries, chiefly on minor matters; and a considerable number of hands are at present out of employment.

The iron trade continues to improve; a decidedly firmer tone has been perceptible during the last week. Hematite pig iron is obtainable in Sheffield at 58s. for West Coast, and 55s. to 56s. for North-East Coast. Common forge is firm at 39s. 6d. net; bar iron, £5 10s.; Siemens-Martin steels, £7 10s. and upwards; Bessemer billets realise from £5 12s. 6d. to £6 per ton. There is every prospect of the iron trade becoming much brisker, and values advancing considerably very soon.

In railway material the principal orders recently booked have been for the Indian States Railways and several Colonial markets, while some foreign orders of consequence have also been received. These coming in at the same time as the revival in the home market, has made all our firms engaged in the production of axles, tires, springs, buffers, and similar goods, as well as in railway carriages and wagons, extremly busy. It may be doubted if at any previous time more work has been in hand in railway specialities for immediate delivery. Prices for finished productions are therefore gradually stiffening, and the amount of work on the books puts makers in a position to ask for higher values for future orders.

Marine material is also in a much brisker condition. Freights are still very low, owing to there being more ships than cargoes for them, but there is a considerable amount of new work in hand which brings employment to some of our workshops, particularly in shafting, castings, propeller blades, flues, tubes, flanged boiler end plates, &c. Messrs. John Brown and Co., who are sole manufacturers of Purves flues and Serve tubes, report a good business. They are also doing well in marine type boilers with Ellis and Eaves' suction draught. These are being made for electric light and works installations, in addition to their use for ships' boilers. One electric light company in London has fitted these boilers to its works, and a similar class of boiler has been ordered from Messrs. Brown and Co., by the Sheffield Electric Light and Power Company, and the Bradford Corporation, who have previously been customers for the same class of boiler. This company are also constructing four similar boilers for Johannesburg.

Orders for war material are not coming in, apart from armour-plates and gun forgings, with such rapidity as was expected, and even in gun forgings the powers of output of the Sheffield firms are not at all fully in operation. The smaller classes of shot and shell are being freely booked, but there is altogether inadequate work for the plant in readiness to produce the large armour-piercing projectiles. Orders for these war goods cannot be much longer delayed, and Sheffield is bound to participate in the requirements for them under the Naval Estimates. It has been stated that while three firms in France can produce any quantity of 16¼in. shells that the French authorities may require, there is not a firm in England capable of making that large shell at all. This is not correct. Messrs. Thos. Firth and Sons, Norfolk Works, can make these shells, and are ready to do so whenever the Government please to forward their orders. This firm alone could produce more of these shells, as well as 12in. and other large sizes, than the Government is likely to require.

In the lighter trades the condition of affairs is increasingly gratifying, as well as in the engineering departments and steel. With regard to the latter there is a steadily improving demand both at home and abroad for the best crucible material, as well as for Bessemer and Siemens-Martin qualities. Makers of agricultural and horticultural implements report that they are exceedingly well off, and the call for scythes, sickles, &c., for which, in spite of machinery, there is a great business in Sheffield and for miles around, is greater than ever. Cutlery is rather better than previously reported, though not so brisk as at the close of last year, while there is a distinct weakening in the demand for electro-plate and sterling silver goods. The latter feature is more evident with the smaller firms than in the large establishments. The rolling mills, which are the best key to what are known as the Sheffield trades, are satisfactorily employed, and it may, therefore, be taken for granted that good employment will continue to be given in the lighter staple industries.

The Sheffield Gas Company, at its half-yearly meeting on the 9th inst., decided to reduce the price of gas to all classes of consumers by 2d. per 1000 cubic feet. This makes the price, according to the qunatity consumed, 1s. 8d., 1s. 10d., and 2s. per 1000 cubic feet. Sir Frederick Mappin, Bart., M.P., the chairman of the company, stated that the quantity of gas consumed had largely increased during the half-year, the weight of coal carbonised being 5680 tons in excess of the quantity in the corresponding half-year of 1894. He expressed the opinion that gas was still in its infancy.

The weight of Yorkshire coal—part Derbyshire—taken to Hull in February was 153,392 tons, as compared with 143,520 for the corresponding period of 1895; for the two months, 304,336 tons against 286,096 tons. The weight exported in February was 40,117, against 32,199 tons; for the two months of the year, 96,569, against 85,972 tons. The principal customer has been Germany, with 22,953 tons, against 14,101 for the corresponding two months of 1895.

Sir P. Salter Pyne, the engineer in charge of the Ameer of Afghanistan's gun, rifle, and cartridge factories at Cabul, visited Sheffield on Monday, when he inspected the works of Messrs. Thomas Firth and Sons, steel and war material manufacturers, and Messrs. George Butler and Co., cutlery manufacturers, Trinity Works, Eyre-street, Sheffield.

The order for the whole of the tool steel required in the Government arsenals and rifle factories for a period of three years has been placed by the War-office with Messrs. Jonas and Colver, Continental Steel Works, Sheffield.

THE NORTH OF ENGLAND

(*From our own Correspondent.*)

GENERALLY a lull in business is noticeable this week, but after the activity in the demand that has been experienced for some time past this is not considered of much importance, as such periods of quietness are not unusual during the progress of all revivals. The dulness is looked upon as likely to be of very short duration, and all round prices are well maintained, because as a matter of fact manufacturers are so well supplied with contracts that they are for the present independent of the market. If they were so disposed, however, they could book extensive orders for summer and autumn delivery, and there are plenty of inquiries for iron for delivery between May and August, but the prospects are so encouraging that sellers do not care to commit themselves so far ahead. Travellers who have been on their business tours through the various iron manufacturing districts give most excellent accounts of the progress of trade; indeed, in some parts the activity was never so great, and there is every prospect of its being continued. All who are needing iron and steel are making haste to get it, as the longer they wait the more they will have to pay for it. The dullest part of the year is now ended, and if prices advance, then they may be expected to rise still further when the briskest season has arrived. Railway companies, municipal authorities, engineers, &c., both at home and abroad, are ordering freely. Almost all the manufacturers in this district have their books well filled with contracts, and the number of the unemployed has within the last two or three months very appreciably decreased; indeed, in the iron and engineering industries it is many years since employment was found for so many. Shipments are above the average. From the Cleveland district this month the exports of pig iron have been 35,592 tons, as compared with 26,027 tons last month, 23,327 tons in January, and 21,131 tons in March, 1895, all to 11th. As local consumption has also greatly increased, it is certain that the deliveries of iron this month will exceed the production, which has not been the case since last October.

Among the exports from the Tees this week has been noted some pig iron for Huelva, which is wanted for copper catching in the rivers and streams in the South of Spain. Years ago thousands of tons of Cleveland pig iron used to be sent for this purpose. It was made in smaller pigs than those usually cast, so that it could be more readily handled and carried on the backs of mules to the interior. The trade, however, ceased with Cleveland when pig iron began to be made in Spain, as Spanish pig could be supplied at a cheaper rate than English, upon which a heavy duty was levied. The shipment this week is, therefore, important, as it denotes a re-opening of the trade.

Prices of pig iron have been well maintained this week, notwithstanding the lull in the demand, and what has kept makers stiffer has been the announcement that tenders were being asked for 90,000 tons of castings for the new subway in London, which is to be lined throughout with cast iron. No. 3 Cleveland pig iron has been steady at 38s. 6d. per ton for prompt f.o.b. delivery, and makers have not accepted less, while second hands have only sold a few small lots at 38s. 4½d., and that would not be taken now. It has been difficult to meet with a producer who would even quote for delivery further ahead than the end of next month; no one, in fact, has any desire to sell ahead with such promising prospects. No. 1 Cleveland pig has been firm at 39s. 6d., and the inquiry is improving as the regular shipping season approaches. The commoner qualities of pig iron are in better demand than supply, and for No. 4 foundry the price has been advanced to 37s. 6d., while grey forge has been put up to 37s.; mottled, to 36s. 6d.; and white, to 36s., the last-named being almost unprocurable, as there is no stock, and scarcely any is made. Mixed numbers of East Coast hematite pig iron are not under 47s. with makers for early f.o.b. deliveries, but merchants have sold small quantities at 46s. 9d. and even 46s. 6d. Cleveland hematite warrants are considerably cheaper than this, but there is no speculation in them, and consumers do not care to buy them, as they may get a brand which they do not appreciate. Rubio ore is 12s. 9d. per ton, delivered at Tees wharves. The stock of Cleveland pig iron in Connal's public warrant stores on Wednesday night was 186,276 tons, an increase of 766 tons during the month. It will be noticed that the quantity going into the public stores is very small this month—700 tons per week—whereas in December it was 3700 tons. This is partly due to the larger inland deliveries and the heavier shipments, and partly to the fact that merchants just now prefer to let their surplus iron stay in the hands of the makers.

A slight lull in the demand for manufactured iron and steel is reported, but works are fully employed as a rule, and prices are firm all round. Heavy steel rails are kept at £4 15s. net at works by the syndicate, notwithstanding that orders are going into the hands of the foreigners from customers who have hitherto bought in England, but who can now buy cheaper elsewhere. For stee ship-plates £5 2s. 6d. is quoted; for steel boiler-plates, £6 2s. 6d. for steel ship angles, £5; for iron ship-plates, £5; for iron ship angles, £4 15s.; and for common iron bars, £5, all less 2½ per cent. and f.o.t.

Engineering is very brisk on the whole, some firms being better off for contracts than ever before; but prices do not seem to improve much. The shipwrights on the Tyne, Wear, and Tees have been granted an advance of 1s. 6d. per week in their wages, in satisfaction of their claim for 4s. advance. It is intimated that the engineering works of the Tees-side Iron and Engineworks Company and those of Messrs. Westgarth, English, and Co., both at Middlesbrough, and both acquired by Sir Christopher Furness, will be worked together, and will carry on a much larger marine engineering business than heretofore. Messrs. Westgarth, English, and Co. have informed the Corporation of Middlesbrough that they propose to erect a large crane on the Tees-side Wharf for shipping their machinery, but as the frontage is too short for the large modern vessels which they would have to fit with engines, they ask whether the Corporation would allow vessels to overlap their—the Corporation's—wharf. Messrs. R. Craggs and Sons are removing to the new shipyard which they acquired from Sir C. Furness, who bought it as part of the Tees-side Company's property. Messrs. Craggs and Sons propose to employ electricity as a motive power at their yard. It is being used extensively already at two establishments in the district, one of which saved £4000 last year by its employment.

The directors of the North-Eastern Railway Company have appointed Mr. James Forsyth, of the Mineral Department, Newcastle, to the position of assistant superintendent of the line—trains department—in succession to Mr. Charles Steel, who was recently appointed general manager of the Highland Railway, and Mr. W. S. Roden is appointed passenger superintendent at Leeds, vice the late Mr. Richard Chamberlain.

Sir Andrew Noble, K.C.B., of Jesmond Dene House, Newcastle-on-Tyne, of Sir W. G. Armstrong, Mitchell, and Co., has been chosen as Sheriff of Northumberland, and Major Robert Ropner, of Preston Hall, Stockton-on-Tees, the well-known shipbuilder, will occupy a similar position in the county of Durham.

The death took place on Saturday suddenly, at Redcar, of Mr. John Bowman, aged 57 years. He was a director of the Darlington Wagon and Engineering Company, and also managing director of the Low Beechburn Colliery. The death also took place of Mr. W. G. Younghusband, of Darlington, manager of the outside machinery department of the North-Eastern Railway; also of Mr. Charles Brown, of Brown Brothers, ironfounders, Portrock-lane Ironworks, Stockton.

The Middlesburgh Chamber of Commerce is instituting an inquiry as to how far foreigners have encroached upon the trade of local manufacturers during the last five years, and which are the nations which have so encroached.

The coal trade is generally quiet, the condition of business being thus the exact opposite to what is reported in the iron trade. Especially in the steam coal branch is the demand slack, and few of the Northumberland collieries are working to their full capacity, nor are they likely to do so until the Baltic shipping season opens. The exports of coal from North-eastern ports last month amounted to 1,326,730 tons, or 204,437 tons more than in the corresponding month last year, when exports were much curtailed on account of the severity of the weather. The present price of best Northumberland steam coal is 7s. 9d. per ton prompt f.o.b. delivery, and 8s. 3d. is accepted for delivery over the season. The Osmondcroft Colliery, near Winston, between Barnard Castle and Darlington, has ceased working; it is a landsale colliery, started some years ago by the late Mr. R. Teasdale, of Newsham, and latterly has been worked by the Osmondcroft Coal, Brick, and Tile Company. The Marley pit at the Hulton Henry Colliery, near Castle Eden has been closed owing to the influx of water, and will probably be idle for some months until the pit is cleared. The Longhurst Colliery, in Northumberland, has been stopped owing to the exhaustion of the coal. The Sunnybrow Colliery, in Durham, which has been idle for some years, is to be re-opened. Good Durham blast furnace coke is firm at from 13s. to 14s., delivered at Middlesbrough furnaces. Large quantities have been sold during the last fortnight at 14s. per ton.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been less firmness in the Glasgow pig iron market this week. On Monday Scotch warrants were done from 47s. 7½d. to 47s. 3½d. cash, and 47s. 10d. to 47s. 7d. one month; the transactions having since been about the lowest rates. Cleveland iron has sold from 38s. 8d. to 38s. 5½d., and Cumberland hematite 49s. 2d. to 48s. 9½d. cash. The decline in prices is ascribed to holders selling from apprehension of a dispute in the mining industry following on the present reductions of wages. A large quantity of iron changed hands. The increased reports shown by the Board of Trade returns had only a slight and temporary influence on the market, because it was at once perceived that this increase is counterbalanced by the additions that are being made to output and stocks. The market was in the hands of the bears to a greater extent this week than for some time past. At the same time the state of the iron trade is, all things considered, not unsatisfactory; the home consumption of all kinds of pigs being on a constantly increasing scale.

Since last report an additional furnace has been put into blast at the Carron Ironworks, and the total number now blowing in Scotland is eighty, compared with seventy-four at this time last year. The output is at present larger than the current demand, so that both public and private stocks are increasing, the past week's addition to the stock in the Glasgow warrant stores being upwards of 1800 tons. These stocks are still, however, considerably smaller than the average of recent times, and the manufacture of pig iron is being conducted at so moderate a cost at present that the ironmasters are disposed to sell as much as they can at current rates for the store, adding at the same time to their private holdings. They have a better chance of selling to advantage in the future than has the speculator, who now invests in warrants, because there is a risk of prices going lower in the open market.

The following are makers' pig iron prices f.o.b. at Glasgow: — Govan, Monkland, and Carnbroe, No. 1, 48s. 6d.; No. 3, 47s.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, Calder, and Summerlee, No. 1, 51s.; No. 3, 48s. 6d.; Coltness, No. 1, 53s. 6d.; No. 3, 49s.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 47s.; Eglinton, No. 1, 48s. 6d.; No. 3, 46s. 6d.; Dalmellington, at Ayr, No. 1, 48s.; No. 3, 46s.; Shotts, at Leith, No. 1, 53s.; No. 3, 49s.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

There has been some disappointment that the increase that occurred in the shipments in the past two weeks has not been maintained. The past week's clearances at the various ports amount to 6517 tons, compared with 7259 in the corresponding week of last year. To Germany 575 tons were despatched; United States, 138; Australia, 305; South America, 110; India, 55; France, 25; Italy, 550; Holland, 670; Belgium, 65; other countries, 584; the coastwise shipments being 3440 tons, against 5254 in the corresponding week of last year.

In the malleable iron and steel departments there is much animation, the works being for the most part in full operation, and turning out a large quantity of material, most of which is being disposed of to home users. Prices are steady and fairly well maintained, but they are still much lower than would be desired.

The coal shipments at the Scottish ports in the past week reached 119,875 tons, against 117,180 in the preceding week, and 95,765 in the corresponding week of last year. An improvement in the Mediterranean trade has kept up the shipments, the clearances both from the Clyde and Forth in that direction forming a very considerable proportion of the whole. Business in the freight market this week would seem to indicate that the shipments to the Mediterranean in succeeding weeks are likely to be on a scale above the average. The demand for the better qualities of shipping coal is thus fairly good, but the market generally shows no improvement, and quotations at Glasgow are purely nominal. In Ayrshire the depression is severe, and prices are reduced 2d. to 3d. per ton for shipping qualities. House coal is quoted f.o.b. at Ayrshire ports, 6s. 3d. to 6s. 6d.; steam and main, 5s. 9d.; triping, 5s.; dross, 3s. to 3s. 6d. per ton.

The coalmasters of Lanark and Ayr have intimated a general reduction of 6d. per ton in the colliers' wages. This will press with much severity upon the men, who were already suffering much from partial reductions and curtailment of working time. In many places only three to four days' work per week can be obtained, and now that wages run from 4s. to 4s. 6d. per day, it scarcely requires to be explained that the men are in a most unfortunate position. Of course this is well known to the masters, by whom it is deplored; but they are not able to make the state of matters better. It is not easy to perceive how the reductions will operate. The colliers are holding meetings, protesting and threatening to resort to idle days in order to still further reduce output; but the working time is already so short that it is not easy to see how such a policy could be carried out at present.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

MARCH, so far, has kept to its old reputation for storms. Fortunately, the chief evil has been in delaying tonnage, the list of disasters having only been of small account. But for the delay of vessels and steamers coming in last week, business would have been a large one. As it was, Cardiff total coal export mounted up to 290,000 tons. At Swansea there have been great complaints of delayed tonnage, and the anthracite coal export was weakened in consequence. Altogether Swansea coal export was from only 22,266 tons, a full third of which went to France. Newport total foreign was 54,071 tons; coastwise, 14,797 tons.

Coal prices have been maintained, and a slight advance shown in small. Latest prices Cardiff indicate this:—Best steam coal, 10s. 3d. to 10s. 6d.; seconds, 9s. 6d. to 10s.; drys, 9s. to 9s. 6d.; small, best, 4s. 9d. to 5s.; seconds, 4s. to 4s. 3d.; drys, 3s. 6d. to 3s. 9d. Monmouthshire coal for shipment at Cardiff is unchanged. Best 8s. 6d.; Eastern Valley coal, 8s.

House coal has varied a good deal in demand. Sometimes an improvement sets in, followed quickly by a decline. "If this is all the winter we are to have," remarked a dealer, "it will be a poor one for house coal." This week it was reported on 'Change, Cardiff, that there is a fair inquiry for prompt shipment, and the following prices are maintained:—Best households, 10s. 6d. to 10s. 9d.; seconds, 9s. 3d. to 9s. 6d.; No. 3 Rhondda, 9s. 6d. to 9s. 9d.; brush, 7s. 9d. to 8s.; small, 6s. to 6s. 6d.; No. 2 Rhondda, 7s. 6d. to 7s. 9d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d. Swansea prices: Anthracite best big vein selected, 11s. to 11s. 6d.; seconds, 10s. to 10s. 6d.; ordinary large, 8s. to 9s.; small rubbly culm, 4s. 6d. Steam coal, 9s. 6d. to 10s. 3d.; seconds, 8s. 8d. to 9s. 3d. House coal, No. 3 Rhondda, 10s. to 10s. 6d.; through, 8s. 3d. to 8s. 9d.; small, 6s. 3d. to 6s. 6d.; No. 2 Rhondda, 8s. 9d. to 9s. 6d.; through, 6s. 3d. to 6s. 6d.; small, 5s. to 5s. 6d. In coke there is a steady demand. Cardiff prices: Furnace, 13s. 6d. to 14s. 9d.; foundry, 15s. 6d. to 16s. 6d.; special, 19s. 6d. to 20s. Swansea prices, 12s. to 17s., according to brand. Patent fuel is improving. Cardiff and Swansea prices firm, 10s. to 10s. 3d. Pitwood at Cardiff is a little better in demand, price 15s. 3d.

The state of unrest which has of late been exhibited in several of the coal valleys, promises to become widespread. The colliers are literally up in arms against the "Discharge Note System," and this time are championed by "Mabon," Mr. Abraham, M.P., who at a large meeting on Monday at Cardiff, attended by representatives of nearly 100,000 colliers, denounced it heartily. The opinion of the meeting was thoroughly in favour of giving a month's notice unless the discharge note system is summarily ended. On Tuesday the Sliding Scale Committee met and discussed the matter, but did not come to a decision. This is expected on Saturday. Sir W. T. Lewis, Bart., was unable to be present at the last meeting on account of a pressure of engagements in London.

There is a good deal to be apprehended when Mabon speaks out unhesitatingly, for he is a judicious and a discreet leader, and more frequently curbs in than incites to action. It is the opinion of many who usually support the coalowners, that a withdrawal of the measure would be a prudent step at present, and then, in joint committee, "owners" could frame some rule that would give the industrious and peaceable some advantage over those who habitually indulge in strikes.

The Plymouth strike, or lock-out, continues, and widespread destitution is occurring in many quarters. Some of the thrifty are, so far, unaffected, but at all of the large Welsh collieries there is a considerable number of the labouring class, principally Irish, and it is these and their families who suffer most. The impression in the district is growing that if the sliding scale cannot reach the case and bring it to an end, it is time for compulsory arbitration to be enacted. The Plymouth case is said to teem with difficulties. On the one hand it is urged that men have been able to earn good money there, and that the benefit of late has been more with the colliers than the employers. A plea was started by the men that some allowance should be made at a certain point of the work, and this was conceded, and withdrawn when the difficulties were overcome, but having had the allowance, the men insist upon its continuance, and this is refused. Such is one view of the situation; and it is believed, in sound quarters of observation, that the proprietary will support their representative to the bitter end. If it can be shown that at the late wages Plymouth collieries cannot pay to be continued, the miners' leader, one would think, should advise the acceptance of such a reduction as would warrant a continuance. The men forget that the old collieries—and a part of the Plymouth coalfield was worked 100 years ago—are handicapped by the deep sinkings of Dowlais, Cardiff, Aber, Albion, and others which are of recent date. Yscuberwen, in the Aberdare valley, after sixty years' work is to be closed, and the plant is to be removed.

The year has begun fairly well so far as iron and steel are concerned, though the totals of February, as regards exports from Cardiff, were not equal to those of January. Newport and Swansea showed better. In January Swansea despatched 8949 tons; February, 2632 tons. Newport in January sent away 314 tons, and in February 2193 tons. Swansea, in January, 130 tons, and in February 2515 tons. Llanelly sent none away in January, but 470 tons in February.

On 'Change, Cardiff, it was reported this week that numerous inquiries have been received for steel rails, and a moderate demand for steel bar at last prices, namely, Bessemer bar, £3 17s. 6d.; Siemens best, £3 18s. In merchant bar and small goods there is a tolerable amount of business being done.

The pig iron market is firm and advancing, and there is a steady demand for iron ore at the following prices:—Best Rubio, 11s. 9d. to 12s.; Tafna, 11s. to 11s. 3d.; Garucha, 10s. 9d. to 11s. c.i.f.

Swansea report is not quite so satisfactory in respect of pig iron, prices having slightly receded since last week, the quotations being a few pence less. In other branches distinct improvement is shown.

The finished iron and steel trades are very busy. The demand for steel for ship plates, boiler plates, and galvanising sheets is decidedly increasing. I am glad to learn that the orders for the latter are coming in strongly from the Colonies and India, and a large and important business is anticipated.

The Swansea Hematite Company, the Ebbw Vale, Cyfarthfa, and Dowlais Iron Company continue to be large importers of ore, principally from Bilbao. Cyfarthfa continues, notwithstanding the flagging condition of the tin-plate trade, to do moderately well in tin bar, so that should a revival in tin-plates occur the problem would be how to meet the demand. On a personal visit a few days ago I was impressed by the activity shown, the greater part of make being in steel bar. Iron and steel cargoes for the week have been small, ore went to La Guayra. Last week that fine specimen of a turret ship the Oak Branch left Cardiff with 5000 tons of coal for the Cape.

The opinion of leading men in Swansea upon the tin-plate situation is that though there may be "ups and downs," it will be hopeless to expect a steady and an improving trade, unless a systematic reduction of wages takes place. It is a matter of surprise amongst the iron workers that a leaf has not been taken from their book. In former years high wages prevailed at Cyfarthfa and Dowlais. Gradually, however, this was changed, especially when iron gave way to steel, and it is only by the adoption of the best scientific and mechanical appliances, and the introduction of cheap labour, that the "mill works" are kept going. Wages are much higher in the tin-plate works than in the general run of iron and steel works; but, as an authority remarks, if trade is to be retained with America they must be lowered.

Last week there was a better despatch of tin-plates to America; about 2000 tons. In all the shipments of plates totalled, 32,846 boxes. On the other hand, the make was 38,853 boxes, so stocks were again increased. Total stock at Swansea now consists of 190,931 boxes. Some of the works which restarted, having completed the orders obtained, are likely to stop again, and it was stated on 'Change, Swansea, this week that, if they are laid by, no restart will again be made until there has been a regular revision of wages. I hear that a restart is intended at the Avon Vale Tin Plate Works, Port Talbot, with three mills.

Iron, steel, and tin plate quotations at Swansea this week were as follows:—Pig iron, Glasgow warrants, 47s. 4½d., cash. Middlesbrough No. 3, 38s. 7d. prompt. Hematite, 46s. 2d. Welsh bars, £5 10s. to £5 15s. Sheet iron, £6 15s. to £6 17s. 6d. Steel sheets, £6 12s. 6d. to £6 15s. Steel rails, heavy, £4 10s. to £4 15s.; light, £4 17s. 6d. to £5 7s. 6d. Bessemer steel, tin-plate bars, £3 17s. 6d. Siemens, best, £3 18s. Tin-plates, Bessemer steel cokes, 9s. 1½d. to 9s. 3d. Siemens, 9s. 3d. to 9s. 6d.; ternes, per double box, 17s. 6d., 18s. 6d. to 22s. 6d.; best charcoal, 12s. 6d. to 13s. 6d.; wasters, 6d. to 1s. less. Block tin is £60 15s. to £61. In copper there has been a run down, probably due to speculative operations. Chili bars are at £44 16s. 3d. to £44 17s. 6d. Swansea Harbour revenue last year was the largest on record.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

ALL sorts of iron and steel continue in lively and regular demand, and the prices paid are on the whole satisfactory. For some articles quotations have been officially raised.

On the Silesian iron market a good trade is doing, both in raw and in finished iron. The rolling mills will be regularly engaged till far into the third quarter, orders for local as well as for foreign demand coming to hand freely. The activity in the malleable iron trade naturally has a favourable influence on crude iron, and there has been a decided improvement noticeable in the occupation of the blast-furnace works lately. There is also much briskness noticeable in the railway and engineering trade, the shops being generally employed to the extent of their capacity.

In Austria-Hungary the iron and steel industries are tolerably active. Demand on home and on foreign account is undoubtedly improving, and there is likewise an upward tendency to be perceived in quotations; sheets, for instance, and galvanised plates have been raised 50 cr. per 100 kilos. The inquiry for girders is strong, and that for bars increasing from week to week. Wire and wire nails are still extremely neglected, the advance in quotations, which was to take place on the 1st of March, having again been put off—till next month perhaps.

The reports concerning the French iron and steel trade are pretty favourable this week. Demand is good and prices tend upwards. There has not been much business done in bars and structural iron hitherto, and girders still stand on 145f. p.t., Paris, both for inland and foreign consumption; but a good spring demand is anticipated. For rails and general railway rolling stock there has been a moderately good inquiry experienced, quotations being a trifle more paying than before. In 1895 the French railways consumed 85,244 t. of steel rails, against 110,609 t. in 1894, 129,338 t. in 1893, 163,840 t. in 1892, 112,857 t. in 1891, 66,844 t. in 1890, 58,046 t. in 1889, 93,868 t. in 1888, 108,898 t. in 1887, and 170,595 t. in 1886.

The Belgian iron business is progressing favourably, demand increasing from week to week, while quotations show considerable firmness, and have even been raised in a few instances. The blast furnace works of Luxemburg have officially advanced their quotations 1f. p.t., foundry pig No. 3 now standing on 48f. p.t. Compared to October last year, prices have risen about 4f. p.t. Some pretty large export orders for bars and plates have been booked recently. Rhenish-Westphalian iron masters report themselves most satisfactorily situated with regard to employment, the amount of orders booked increasing from week to week. Quotations, though much more favourable than at the end of last year, are still, in a great many instances, far from paying. Up to the present time production has been tolerably large, in many cases exceeding consumption, which is due to the hitherto rather limited demand on foreign account. In the Siegerland the price for foundry pig has been raised M. 1 p.t., No. 3 now fetching M. 57 p.t.; forged pig was also advanced M. 2 p.t. free Siegen. The demand for malleable iron continues to show a satisfactory improvement, and prices are exceedingly firm. Inquiries for bars are very numerous, girders and hoops likewise meeting with healthy request.

The steel trade is very active, both in the merchant and manufactured branches. Plates and sheets sell briskly; prospects with regard to further employment are good, and a rise in quotations is likely to take place in a week or two. At present very little is gained, makers having to pay too much for the raw material. Especially for export to Russia very low prices have to be quoted, which in many cases not only yield no profit, but entail loss. However, the plate makers are well aware of the importance of the export trade to Russia, and will rather forego a profit than lose their customers. During the first eleven months of last year no less than 44 millions of kilogrammes of plates were sent from Germany to Russia. Wire and wire nails are in better request, but only very low prices are quoted. Total output of pig iron in Germany, including Luxemburg, was, for January, 1896, 517,988 t., of which 142,622 t. were forge pig and spiegeleisen, 31,345 t. Bessemer, 263,301 t. basic, and 80,720 t. foundry pig. Production in January, 1895, was 489,575 t., while in December of 1895 it amounted to 510,405 t.

German export in rails has, of late, decreased, as may be seen from the following official figures:—

	Tons.		Tons.
1860	1,270	1887	174,226
1870	36,000	1888	114,946
1875	132,000	1889	110,949
1880	230,204	1890	130,837
1881	250,700	1891	142,846
1882	186,054	1892	118,712
1883	176,178	1893	87,360
1884	144,464	1894	119,410
1885	164,799	1895	116,627

Export in fish-plates, sleepers, &c., has, on the other hand, developed favourably, being for—

	Tons.		Tons.
1880	8,147	1888	23,254
1881	11,982	1889	26,042
1882	11,596	1890	36,470
1383	19,230	1891	63,406
1884	17,536	1892	39,558
1885	26,929	1893	37,487
1886	22,820	1894	43,343
1887	21,553	1895	45,619

With regard to export trade in springs, axles, buffers, &c., for railway carriages, an improvement has been noticeable lately. Export was as under:—

	Tons.		Tons.
1880	18,722	1888	20,808
1881	17,084	1889	26,030
1882	11,822	1890	29,114
1883	13,050	1891	33,554
1884	10,152	1892	26,554
1885	8,603	1893	29,714
1886	12,597	1894	24,318
1887	22,447	1895	25,824

The following figures show German export in locomotives and traction engines:—

	Tons.		Tons.
1883	13,735	1890	5117
1884	9,912	1891	4174
1885	6,778	1892	4778
1886	7,953	1893	4507
1887	6,872	1894	5686
1888	7,088	1895	7988

In the year 1880 no less than 2222 railway carriages were exported, in the following year 3108, while in 1885 only 1071 railway carriages were exported. In 1890 export again rose on 3575 carriages, and was for 1894, 4667; and for 1895, 6040 railway carriages.

A HUGON GAS ENGINE.—Messrs. Richard Grice and Son, of 108, High-street, Clapham, write us that they have one of the Hugon gas engines, No. 69 of 1867, which they are now removing to provide space for other things. It is of one nominal horse-power, in working order, and would be an acquisition for an engineering museum. There is already a half-horse power Hugon engine in the Patents Department of the South Kensington Museum, but it is not fitted with the Hugon igniting arrangement, so it may be hoped that this now available specimen, as it can be had at a low price, may be purchased for some museum, rather than be put aside and ultimately to the scrap heap.

ANOTHER ECONOMICAL ENGINE.—The report of an economy test made by Messrs. Dean and Main, mill engineers, of Boston, Mass., upon a 26in. and 52in. by 72in. cross-compound Corliss engine at the Berkeley Mill, Berkeley, R.I., made by the Corliss Steam Engine Company, of Providence, showed a steam consumption of 12·86 lb. and a coal consumption of 1·39 lb. per horse power per hour. The boilers were of the Corliss vertical type. The high-pressure cylinder was jacketed with steam at boiler pressure, and the low-pressure cylinder with steam of receiver pressure. The air pump was operated by the engine. The steam supplied the engine was superheated 18 deg., and was at a pressure of 129 lb. The vacuum was 27·4in. The boiler test showed that the economiser with which the plant was equipped produced a saving of 4½ per cent. The report states that the engine was tested in its "everyday working condition, and the results, which have been seldom equalled or surpassed for economy, are being constantly duplicated in the regular operation of the mill." The best economy as known of for compound mill engines was 12·46 lb. of steam per indicated horse-power per hour, which was found by Mr. Barrus in testing the Wheelock engine at the Grosvenor Dale Mill. The *Engineer Record* says this engine was arranged on the Rockwood system; that is to say, it resembles a triple-expansion engine with the intermediate cylinder left out, and worked under a pressure of 150 lb. Mr. Dean's test of the Leavitt pumping engine at Louisville, Ky., showed a consumption of 12·15 lb. of dry steam per indicated horse-power per hour.

AMERICAN NOTES.

(*From our own Correspondent.*)

New York, March 21st.

The declining tendency in prices continues. This, with the unsatisfactory financial condition, accounts for existing dulness in trade and manufacturing circles. Good securities are in demand. Bank clearings are now one-third higher than a year ago. Railroad earnings show an improvement so far this month, 13½ per cent. in excess of same time last year. The country has lost 262,000,000 dols. within eighteen months on low tariffs and on borrowed money. The Treasury is still falling behind, and must continue to do so until higher duties are imposed. Exports at New York for February are 19 per cent. greater than last February. Iron and steel are selling about as usual, and prices are steady. Prospects for the coming season are good, and the year will probably be the best the States have had since 1892. Ship, boat, bridge, and car building, all are improving. The other industries are gaining, but low prices everywhere rather discourage enterprise. The silver question is still aggravating the public mind. Gold production in the spring will begin on a greater scale than ever. Mining enterprises are multiplying, and new fields of great value are to be opened and worked by organised companies well supplied with money. Coal is very low, and attempts are being made to restrict production.

Commercial activity in eastern and western markets have been gradually increasing, but has not yet reached stimulating proportions. Speculators are afraid. Commercial paper is scarce. The Government is hobbling along, hugging its new found gold, but financiers say, "Grover will be around again before long." The silver men in the Senate showed their teeth the other day, and let their lips drop over them until the St. Louis Republican Nominating Convention meets in the early summer. Then there will be a grand party split, a fact apparent to all but New York editors and Wall-street bankers. The iron and steel trades are active. Heavy orders are coming for wrought iron and cast pipe, for skelp iron bars, plates, and shapes. The expansion in steel making is rapid. Thirty open-hearth steel furnaces have been added within a year, more are projected. Present open-hearth capacity over one million tons per annum. Billet making capacity is being increased. Merchant iron mills are now busier than for months. Spring requirements are opening up. Building operations in cities will greatly exceed last year. Should enterprise receive any genuine encouragement, there will be a great increase in demand. Capital feels encouraged in the belief that circumstances are all favourable for a busy year. Car and locomotive builders are buying material, and many railroad companies are now asking for quotations on track material, machine shop requirements, &c. Manufacturers are anticipating a sudden demand before long for iron and material for numerous construction requirements.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

Steam coal in fair demand, but shipments are delayed by the stormy weather. House coal in moderate inquiry, with prices steady. Tin-plates without change. Manufactured iron and steel continue in good demand.

Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 8s.; house coal, best, 10s. 3d. to 10s. 6d.; dock screenings, 5s.; colliery small, 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 47s. 6½d.; hematite warrants, 49s., f.o.b. Cumberland; Middlesbrough No. 3, 38s. 7d., prompt; Middlesbrough hematite, 46s. 4½d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails, heavy sections, £4 15s.; light ditto, £5 to £5 5s. f.o.b., Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 5s., all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s. 1½d.; Siemens coke finish, 9s. 4½d.; ternes, per double box, 28 by 20 C, 21s. to 22s. Pitwood: 15s. 3d. to 15s. 6d. London Exchange Telegram:—Copper, £45; Straits tin, £60 13s. 9d. Freights firmer.

LAUNCHES AND TRIAL TRIPS.

The trial trip of the twin-screw passenger steamer Douro took place on Thursday last on the river Ribble. This vessel is fitted out for passenger service on the river Amazon, and is also fitted out with electric light and a powerful search-light. On a mean draught of 4ft. 6in., the speed obtained was eleven knots, the weather at the time being most unsuitable for the trial trip of a steamer having three decks and on such a shallow draught, it blowing a gale of wind all the time, but in spite of this the vessel behaved herself in every way satisfactory. She sailed for Para on the 9th inst., and is expected out there in about twenty days. Length between perpendiculars, 120ft.; beam, 26ft.; depth, 6ft. 6in. at middle.

On the 3rd inst. Messrs. Blackwood and Gordon, engineers and shipbuilders, launched from their building yard at Port Glasgow a handsome steel screw steamer for service in the cross-Channel trade between Ireland and England. This steamer has been built to the order of the City of Dublin Steam Packet Company, of Dublin, for their Dublin and Liverpool trade, and is built on similar lines to the fine steamers Louth and Wicklow, also constructed by Messrs. Blackwood and Gordon for the same owners, which vessels have become prime favourites with the travelling public, and also owners of cattle. On leaving the ways the vessel was named Carlow by Mrs. Bell, wife of Captain George R. Bell, R.N., marine superintendent of the company at Liverpool, and was afterwards taken into the builders' wet dock within their works to receive her machinery, which has also been constructed by the builders. Her dimensions are:—Length, 260ft.; breadth, 34ft.; depth, 16ft. 9in.; with long poop bridge, and forecastle and short wells filled in, and having a tonnage of 1250 tons gross register; engines of the triple-expansion type, with bronze propeller, and large boilers working up to fully 3000-horse power.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

27th February, 1896.

4361. Expanding Propeller, J. Hale, London.
4362. Sail, H. Davies, Cardiff.
4363. Well-feed Sieves, T Freeman and S. Spokes, Banbury.
4364. Brakes for Vehicles, C. Carrie, Dundee.
4365. Balloon Propeller, S. Vincent and D. T. Dyke, Salisbury.
4366. Shooting Games, O. C. Krause and F. A. Hüller, London.
4367. Soles for Boots, Shoes, &c., W. C. Rossiter, Devon.
4368. Locking Railway Carriage Doors, J. H. Exley, Bradford.
4369. Electric Cables, C. J. Wightman and A. Hudson, Bradford.
4370. Winding Yarn, J. Senior and L. C. Wallace, Bradford.
4371. Electrical Resistance, &c., A. D. Hughson, London.
4372. Belt Fasteners, I. Jackson, Manchester.
4373. Manufacture of Spirit Varnish, J. Bradley, Manchester.
4374. Bolt Belt Fasteners, I. Jackson, Manchester.
4375. Inflating Apparatus, G. D. MacDougald, J. Sturrock, and R. S. Baxter, Forfar.
4376. Set Squares, E. Bond, Glasgow.
4377. Pneumatic Tires, L. T. Darnault, London.
4378. A New Toy Camera, H. C. Braun, London.
4379. Swings, J. W. Phipps, J. F. Bullock, and J. Thompson, London.
4380. Photographic Shutters, R. J. S. Simpson, London.
4381. The Leg of Mutton Holder, R. W. Woodcock, Suffolk.
4382. Sunshades for Seats and Chairs, F. J. Millard, London.
4383. Nozzles of Pipes, H. A. Murphy, London.
4384. Bows, Neckties, &c., T. W. Perera and J. Leigh, Manchester.
4385. Advertising Tablets, &c., E. F. Lawrence, London.
4386. Travelling Wardrobes, C. M. A. Cuddon, London.
4387. Corks for Bottles, A. J. Colbert, London.
4388. Securing Condenser Tubes, J. R. Mitchell, Glasgow.
4389. A New Cover for Cycles, L. F. Arbuthnot, London.
4390. Attaching Handles to Broomheads, A. Shackley, London.
4391. Indicating the Names of Railway Stations, A. Todd, London.
4392. Steam Boiler Furnaces, J. Apsey and F. B. Hill, London.
4393. Electric Incandescent Lamps, G. Bamberg, London.
4394. Incandescent Gas Lamps, G. Bamberg, London.
4395. Manufacture of Rugs and Carpets, G. Hornig, London.
4396. Cycle Wheels, J. H. Smith, London.
4397. Means for Steering Cycles, A. W. McL. Keen, London.
4398. Mounting and Carrying of Maps, L. Bury, London.
4399. Sign Posts, A. O. Haslewood, London.
4400. Bearings for Velocipedes, J. Lofts, London.
4401. Funnels, A. O. Haselwood, London.
4402. Consuming Acetylene Gas, W. B. Kirkwood, London.
4403. A New Rest or Support for Cycles, M. Rowley, London.
4404. Switches, B. M. Drake and J. M. Gorham, London.
4405. A New Game with Cards, R. Staniland, London.
4406. Electrical Storage Batteries, E. A. McLachlan, London.
4407. Concentration of Acids, J. E. Campbell and J. Keating, Manchester.
4408. Weighing Granular Material, W. Evans, Manchester.
4409. Golf Tees, W. I. Hadden, London.
4410. Metal Loops for Leather Straps, E. T. Keeler, London.
4411. Manufacture of Rollers, &c., F. W. Oliver, London.
4412. Connections for Cranks, &c., M. D. Rucker, London.
4413. Variable Speed Gears, H. H. Griffin, London.
4414. Boats, J. H. Hutchings, London.
4415. Brewing, E. Lofts and G. H. R. Dabbs, London.
4416. Skirt Band and Belt Fasteners, W. A. Thornton, London.
4417. Applying Stay Wires to Fences, E. F. Groom, London.
4418. Evaporating Apparatus, H. H. Lake.—(*W. F. Jobbins and J. van Ruymbeke, United States.*)
4419. Making Hydrogen Gas, J. C. Hanauer, London.
4420. Furnaces, &c., T. H. Lucas and H. B. Martin, London.
4421. Incandescent Gas Mantle, J. Anderson.—(*W. Anderson, Germany.*)
4422. Zinc, The Exploring and Gold Mining Association. - (*S. H. Emmens, United States.*
4423. Cycles, J. Truffault, London.
4424. Fire Escapes, A. Paisley, London.
4425. Calculating Machines, E. Runge, London.
4426. Transmission of Force, S. Hartmann and E. Falke, London.
4427. Armatures, H. F. Parshall and The British Thomson-Houston, London.
4428. Burglar, Police, or Fire Alarm, A. Wilson, London.
4429. Cleaning the Wheels of Cycles, A. and R. Wilson, London.
4430. Machine Guns, W. Cordts, London.
4431. Suspension Lamps, O. Helfft, London.
4432. Electrical Resistances, W. J. Davy, London.
4433. Liquors, H. Dräger and R. Thiel, London.
4434. Moulds for Secondary Battery Plates, F. King, London.
4435. Knitting Machines, J. White and T. G. L. Miller, London.
4436. Looms, A. Morrison and J. Lees, Knock, County Down.
4437. Horseshoes, W. B. Bromley, London.

28th February, 1896.

4438. Bronzing Machines, O. Jäger, London.
4439. Propulsion of Autocars, &c., H. Noar, Cheshire.
4440. Cycles, T. Horton, near Redditch.
4441. Pulleys, J. B. Mackie and H. R. Sutton, Reading.
4442. Making Metal Tubing, J. H. Ball, Nottingham.
4443. A New Spile or Vent Peg for Casks, T. Hasell, Bristol.
4444. Propelling Boats, H. J. Watkins, Birmingham.
4445. Alarm Clocks, C. Rigby, Keighley.
4446. Shoes for Cycling, R. Barratt, Nottingham.
4447. Textile Spinning Mills, J. Beggs, Glasgow.
4448. Cycle Handle to Contain a Watch, E. W. Paul, Surrey.
4449. Foul Effluents, J. W. Slater and J. Parkinson, Manchester.
4450. Rulers, A. Wilkinson and J. F. Abraham, Bradford.
4451. Distributing Fluids, W. J. Orr and S. Walmsley, Manchester.
4452. Driving Gear for Cycles, W. Rhodes, jun., Manchester.
4453. Cycles, Ward and Whitham and C. Whitham, Manchester.
4454. Fittings for Waist Belts, A. Lovekin, Birmingham.
4455. Boots, H. O. Tilley and C. Jordan, Leicester.
4456. Sock or Inner Sole for Boots, E. Lightowler, Southport.
4457. Rolling Sheep Skins, E. Davies and R. A. Hall, Nottingham.
4458. Beds, T. Morton, Glasgow.
4459. Taking Down Bedsteads, J. A. Crane, Handsworth.
4460. Lamps, J. W. Lea and J. H. Perrins, Birmingham.
4461. Wings of Tower and other Bolts, F. Garland, Barnstaple.
4462. Postal Boxes, J. A. Gransden, Southampton.
4463. Noiseless Action Bracket, W. J. Clarke, Great Yarmouth.
4464. Brad for Glazing Glass, G. W. Kerwood, Southsea.
4465. Attaching Warpers' Beam Flanges, J. Mills, Manchester.
4466. Lamp Extinguisher, J. Krajka, Berlin.
4467. Safety Oil Lamp Extinguisher, H. V. Manger, Richmond.
4468. Game in a Tank of Water, A. A. Mitcherd, Dyffryn Station.
4469. Lifting Growing Turnips, A. Watt, Glasgow.
4470. Saturators, J. A. de Gruchy, Glasgow.
4471. Manufacture of Acetylene Gas, J. C. Hall, H. C. A. Dance, and A. R. Hall, Liverpool.
4472. Wearing Apparel for Cycling, J. Tenenbaum, Liverpool.
4473. Sieve Fittings for Teapots, &c., W. B. Smith, Glasgow.
4474. Fans for Ventilation, A. W. Metcalfe and J. B. Morrison, Belfast.
4475. Buckles for Harness, &c., T. E. Williams, London.
4476. Sizing or Slashing Machines, J. Duckworth, London.
4477. Machinery for Working Stone, F. Trier, London.
4478. Means for Lighting Velocipedes, W. Tice, London.
4479. Puzzle, L. Evans, London.
4480. Slide Valves of Steam Engines, L. Parker, London.
4481. Tooth-brush, E. E. B. Boehmer, London.
4482. Wheel-guard for Velocipedes, E. E. B. Boehmer, London.
4483. Absorbent Fabrics, A. Brooks and S. East, London.
4484. Curling Comb, F. G. Kraus, London.
4485. Cushions for Ships, &c., E. W. Frankenberg, London.
4486. Liquid - combustible Burner, G. Ditmar, London.
4487. Securing Hats in Boxes, &c., M. Mädler, London.
4488. Refrigerator, J. G. Davies, London.
4489. Obtaining Alkaline Salts, &c., G. Craig, Glasgow.
4490. Compensated Hot-strip Ammeter, H. B. White, London.
4491. Castors, W. G. Irish, London.
4492. Internal Combustion Engines, F. L. Martineau, London.
4493. Mandrel for Steel and Iron Tubes, C. E. Smith, London.
4494. Appliance for Cutting Thread, E. D. Swinton, London.
4495. Washing Clothes, G. W. B. Crees, R. Ord, and W. H. Brown, London.
4496. Automatic Window Fastening, H. C. Evans, London.
4497. Increasing Pliability of Paper, O. Tietze, London.
4498. Vapour Burner for Oil-stoves, J. T. Armstrong, London.
4499. Books, C. Phillips, London.
4500. Frying-pans, C. Cox, London.
4501. Writing Slates, T. Wignall, Liverpool.
4502. Ladders for Nautical Purposes, D. N. Sinclair, Liverpool.
4503. Collapsible Boats or Baths, M. T. Reade, Liverpool.
4504. Disengaging Gear for Boats, L. T. Gaskill, Liverpool.
4505. Egg-testing Device, T. Lawley, London.
4506. Fire Alarm and Extinguisher, A. B. P. Mowat, London.
4507. Head Coverings, L. Silbertson, London.
4508. Comb, L. Auerbach, London.
4509. Explosives, W. Greaves and E. M. Hann, London.
4510. Putting on Pulley Belts, R. B. Gamble, London.
4511. Lubricating Cans, C. E. Peel and E. Hughes, London.
4512. Knife Cleaner, W. A. Landau.—(*H. Rieger, Germany.*)
4513. Cultivators, J. E. Ransome and F. W. Garrard, London.
4514. Lifting Apparatus for Harrows, R. H. Fowler and T. Benstead, London.
4515. Firing Rockets, E. Beadle and R. White, London.
4516. Gulleys, J. A. Noel, London.
4517. Controlling Stock in Shops, &c., E. Küster, London.
4518. Brushes, W. Candland, London.
4519. Umbrellas and Sunshades, N. and C. Feldman, London.
4520. Packing for Joints, H. C. Platts and T. Lowther, London.
4521. Cylinder Jackets of Engines, W. Naylor, London.
4522. Railway Signalling Apparatus, J. G. Weir, London.
4523. Shields for Water Gauge Tubes, A. Spencer, London.
4524. Horseshoe, W. Chiswell, London.
4525. Bicycles, R. Grilli, London.

29th February, 1896.

4526. Cutting Potatoes and Bread, J. Shackleton, Burnley.
4527. Glass Cylinders, E. J. Shaw, Walsall.
4528. Gulley Traps, J. Staincliffe, Bradford.
4529. Method of Filling Bottles, H. O. Milnes, Bradford.
4530. Filling Substances in Packets, H. O. Milnes, Bradford.
4531. Horseshoes, W. Goudge, London.
4532. Sleeve Grip, G. Sherlock, Dartford.
4533. Swivel Shuttles for Looms, J. D. Whyte and Whyte's Patents, Bradford.
4534. Barring Engines, G. E. Coupe, Stoke-on-Trent.
4535. Heating Water for Boilers, J. Murrie, Glasgow.
4536. Tobacco Pipe Covers, W. Pearce, Birmingham.
4537. Curtain Poles, W. F. Snelling, Norwich.
4538. Oxidising Aniline Blacks, E. Weldon, Nottingham.
4539. Cycle Handle-bars, W. McLean, Glasgow.
4540. Metallic Bedsteads, J. W. Clift, Wellington.
4541. Fixing Metal Hoops to Banjos, A. Tilley, London.
4542. Carriage Shaft Points, J. W. Clift, Wellington.
4543. Drawing Straight, &c., Lines, F. R. Slack, Derby.
4544. Digestine, H. Archer, London.
4545. Polo Scarf, W. A. Tilney, York.
4546. Teaching Arithmetic, W. and M. A. Adam, Glasgow.
4547. Teaching Arithmetic, W. and M. A. Adam, Glasgow.
4548. Production of Oxygen Gas, F. J. Stedman, London.
4549. Circular Knitting Machines, W. H. Payne, London.
4550. Lubricators, W. Chattaway, London.
4551. Steam Generators, O. F. Vollhard, Manchester.
4552. Buckets, M. A. Boardman, Bradford.
4553. Securing Door-mats and Rugs, F. Hulme, Manchester.
4554. Destructors, W. F. Mason, Manchester.
4555. Mud-guards of Bicycles, P. Orlovsky, Birmingham.
4556. Protecting Basket Bottoms, W. P. Ellmore Leicester.
4557. Mechanical Stokers, J. Johnson, Liverpool.
4558. Shaft Bearings, A. M. Robinson, Liverpool.
4559. Velocipedes, L. C. Papenfus, London.
4560. Strainers for Paper Pulp, D. N. Bertram, Glasgow.
4561. Cutting and Sawing Stone, &c., N. Black, Glasgow.
4562. Incandescent Gas Burners, H. Emmett, Dukinfield.
4563. Gas and Air Engines, F. W. Turner, Bury St. Edmunds.
4564. Setter-out for Morticing Machines, W. Nicholson, Newcastle-on-Tyne.
4565. Duplex Oil and Gas Engine, H. A. Thorne, Torquay.
4566. Brass Fire-tongs, H. E. and E. O. Newey, Dudley.
4567. Tires for Bicycle Wheels, H. Edge, Birmingham.
4568. Pipe Hooks, S. Turner and A. Neale, Birmingham.
4569. Draw-benches, G. Platt, Birmingham.
4570. Pneumatic Tires for Wheels, A. J. Johnson, Birmingham.
4571. Safety Targets, E. J. B. Scratton, Glasgow.
4572. Fitting Lengths of Piping, J. B. Blair, Glasgow.
4573. Drill Plough Boards, R. H. N. Sellar, Glasgow.
4574. Soldering Wire on Pipes, R. D. Smillie and J. R. Bird, Glasgow.
4575. Water-closet Seats, F. Sharp and J. E. Leigh, Hurst.
4576. Cycles, F. E. Macmahon and A. J. Postans, London.
4577. Saddles for Cycles, S. Pattison, London.
4578. An Automatic Watch Holder, W. T. Bell, London.
4579. Spittoons for Railway Carriages, H. Walker, Blackburn.
4580. Circular Box Looms, B. Brown, London.
4581. Parcel Carrier for Cycles, &c., J. S. Sayers, London.
4582. Double-lift Jacquards for Looms, G. H. Briggs, London.
4583. Fishing Reels, G. Harrison and D. L. Pexton, London.
4584. Liquids, S. Napper and C. J. Parr, London.
4585. Axle Boxes, R. Kerr and J. N. Patterson, Liverpool.
4586. Spinning Wool, W. Benson and F. King, Manchester.
4587. Cleaning Tobacco Pipes, I. Parkinson, Liverpool.
4588. Cooking Appliance, S. von Ramin, Manchester
4589. Umbrellas and Parasols, A. Berndt, London.
4590. Leaks in Ships, J. Y. Johnson.—(*La Société Anonyme des Forges and Chantiers de la Mediterranée, France.*)
4591. Ash Pans and Fire Guards, W. Brandon, London.
4592. Ventilating Hats, C. Belcher and Messrs. Carlton and Co., London.
4593. Expanding Brace, W. Hooper and M. Martin, London.
4594. Boxes, J. Richmond, W. Whiting, N. P. Hibbit, and C. F. Bowden, London.
4595. Heat Transferring Apparatus, P. Pfleiderer, London.
4596. Swimming Dress, E. W. Frankenberg.—(*E. Frankenberg, Germany.*)
4597. Flushing Apparatus, S. S. Hellyer, London.
4598. Dry Distillation of Wood, A. Schmidt, London.
4599. Fastening Device for Wearing Apparel, E. A. Lumley, London.
4600. Save All for Candles, W. Henley, London.
4601. Refrigerators, L. Bahr, London.
4602. Facing Tiles, &c., J. Holroyd and R. Bond, London.
4603. Metallic Plates, E. G. Brewer.—(*The Société Anonyme des Plaques Lithographiques, Belgium.*)
4604. Apparatus for Evaporating Fluids, E. Theisen, London.
4605. Construction of Wheels, &c., J. R. Harper, London.
4606. Water Pipes, P. Funck and L. Schmidt, London.
4607. Appliance for Testing Milk, &c., C. Oliver, London.
4608. Reaping Machines, W. Jäger and O. Borchart, London.
4609. Tires for the Wheels of Cycles, R. Corsham, London.
4610. Apparatus for Grinding Ores, A. S. F. Robinson, London.
4611. Lowering and Raising Blinds, C. Wenck, London.
4612. Coal Screen for Coal Cellars, B. E. Ferrier, Glasgow.
4613. Boxes for Holding Pile Fabrics, J. Reixach, London.
4614. Rammer for Heavy Guns, J. Vavasseur, London.
4615. Repairing Pneumatic Tires, J. Adair, London.
4616. Tobacco Pipe, G. Goandclément, London.
4617. Electric Railways, C. Coerper, London.
4618. Petroleum and Other Motors, P. Mallet, London.
4619. Conductors of Heat, H. B. Tarry, London.
4620. Apparatus for Displaying Pictures, L. D. E. Gaillard, London.
4621. Viewing Transparent Pictures, J. Joly, London.
4622. Heating Apparatus, W. S. Wallace, Liverpool.
4623. Book Marker, F. J. Measures and F. Adams, London.
4624. Reproducing Sound Effects, M. Hoeft, London.
4625. Sowing Machines, E. Croll, London.

2nd March, 1896.

4626. Preserving Dead Bodies from Decaying, D. Deiches, London.
4627. Construction of Joints, C. Phillips, Birmingham.
4628. Ratchet Braces, E. Walmsley and M. Taylor, Halifax.
4629. Advertising, J. Thornton and F. G. Thomas, Manchester.
4630. Show Card, J. Ferguson and J. H. Silburn, Newcastle-on-Tyne.
4631. Furniture, J. H. Wharton, Liverpool.
4632. Motors, F. H. Royce and E. A. Claremont, Manchester.
4633. Combing Machines, J. and C. F. Crabtree, Bradford.
4634. Gas Engines, &c., W. H. Crow, Newcastle-on-Tyne.
4635. Wire, J. C. Boswell, Norwich.
4636. Flapelle Boxes made of Cardboard, J. E. Thornton, Altrincham.
4637. Cardboard Boxes, J. E. Thornton, Altrincham.
4638. The Save All Fish Frier, J. Goldthorpe, Hull.
4639. Cycle Rest, N. Cockshutt, Preston.

4640. Joints of Pipes, G. F. L. Meakin, Kingston-on-Thames.
4641. Valves, W. D. Wight, M. B. Wild, and T. Rydea, Manchester.
4642. Gas Valve and Pilot Light, W. McCaig, Glasgow.
4643. Loading Rifles, &c., R. Prado and C. Nichols, London.
4644. Bogie Bolsters, J. A. Adey, Sheffield.
4645. Tire Bars, F. R. Booth and W. Carrier, Sheffield.
4646. Driving Gear of Cycles, &c., W. C. Morton, London.
4647. Connecting Baths, Sinks, &c., H. Enoch, Cheltenham.
4648. Box, S. and H. M. Ryder, St. Alban's.
4649. Door Handles, W. Wright and F. J. C les, Plymouth.
4650. Dresses, W. H., R. H., and A. Popplestone, Bristol.
4651. Boilers, A. T. Chorley and W. M. Llewellin, Bristol.
4652. Match-boxes, W. J. Simmons, Bristol.
4653. Grinding Colour, J. Smith and A. Hulse, Longport.
4654. Steam Generators, J. W. Reed, Newcastle-on-Tyne.
4655. Machinery for Winding Yarns, H. Balfe, Manchester.
4656. Union Nuts and Spanners for same, J. Rowse, Derby.
4657. Mining Cages and Hoists, A. and J. Green, Manchester.
4658. Counters, J. S. Howden, Liverpool.
4659. Humidifying and Cooling Apparatus, H. Biedermann, Manchester.
4660. Valves for Pneumatic Tires, A. A. Woodward, Birmingham.
4661. Well-tube Bases or Supports, J. Graham, Glasgow.
4662. Casement Frames and Sashes, F. Stoddart, Glasgow.
4663. Panoramas, I. Greenbury, Glasgow.
4664. Retaining Napkins to the Neck, M. Coles, Glasgow.
4665. Fasteners for Gloves, &c., H. W. Mackenzie, Edinburgh.
4666. Sliding Setting Platforms, W. J. Smith, Southsea.
4667. Soldering Metals, F. F. Barnes and F. Campbell, London.
4668. Transparent Parchment Slips, J. S. W. Tomson, London.
4669. Axle-box, C. Olandt, London.
4670. Spiral Cutter Blades or Edges, H. Smith, Sheffield.
4671. Nails, A. E. Gorse, G. A. Probert, and J. H. Green, Birmingham.
4672. Machinery for Making Rag-pulling Teeth, H. Moss, London.
4673. Fitting for Kitchen Ranges, F. A. Driefürst, London.
4674. Gas Generator, S. S. Bromhead.—(*A. Niel, France.*)
4675. Gear for Overside Cranes, A. H. Mitchell, London.
4676. Making Secure Sash Fastenings, H. P. Miller, London.
4677. Paper, H. Erfurt, jun., and H. Erfurt, Barmen, Germany.
4678. Producing Ornamented Columns of Iron, L. Mannstaedt, Germany.
4679. Dovetailed Joints, D. E. Hunter, London.
4680. Flushing Appliances for Urinals, &c., T. Yorke and W. Pare, London.
4681. Controlling Temperature in Baking Ovens, P. Pfleiderer, London.
4682. Furnaces, H. Kellner and A. Pechl, London.
4683. Bottle Holder, W. Otto, London.
4684. Combination Tool, A. Arnold and K. E. Edge, London.
4685. Composition, W. T. Owen and T. Thatcher, London.
4686. Projecting Kinetoscope Pictures, R. W. Paul, London.
4687. Oars and Sculls, T. Myers, London.
4688. Bolts, H. Bourne, London.
4689. Umbrella Fixtures, H. D. Sabin, London.
4690. Guns, K. Rohr, London.
4691. Pants, I. Frisch, London.
4692. Tipping Buckets, W. T. Andrews, London.
4693. Machinery for Raising and Lowering Goods, C. I. Hall, London.
4694. Furnace Grates, W. P. Thompson.—(*O. Lindner, Belgium.*)
4695. Fire-places, M. Landmann, London.
4696. Marine Steering Gear, T. G. Stevens, Kent.
4697. Coin-freed Apparatus, T. Fryer, London.
4698. Shoes, J. Dawson, jun., and N. Dawson, London.
4699. Ink Bottles, W. M. Johnsen and J. Jögensen, London.
4700. Advertising, P. Sagne, London.
4701. Targets, J. Neuhold, London.
4702. Preventing Bending of Tubes, A. Kirschbaum, London.
4703. Shoes, G. C. Marks.—(*J. Cousins, jun., United States.*)
4704. Game, J. Crabtree and C. Thomas, London.
4705. Pianos, E. Edwards.—(*J. M. Friedrichs, Germany.*)
4706. Automatically Lighting Gas Jets, J. Hombergen, London.
4707. Traction Engines, R. H. Fowler and G. W. Scott, London.
4708. Compound Steam Engines, M. H. P. R. Sankey, London.
4709. Reducing Steam, S. M. Folk and D. S. Ellis, London.
4710. Railway Axle Lubricators, W. Silver, London.
4711. Preventing Refilling of Bottles, A. Guattari, London.
4712. Sustainers for the Wicks of Night-lights, J. C. and J. Field, Ld., and J. Bateman, London.
4713. Manufacture of Alkali Cellulose, C. F. Cross, London.
4714. Substitute for Yellow Phosphorus, M. Bals, London.
4715. Tube Expanders, A. F. Yarrow, London.
4716. Printing Code Symbols, W. Donisthorpe, London.
4717. Filters, C. J. Brown, London.
4718. Treatment of Skins, C. Marter and I. Levy, London.
4719. Pipe Stoppers, J. Jones, London.
4720. Screw Propellers, C. A. F. Meissner, London.
4721. Fur Collarettes, W. Kosky and A. Kosky, London.
4722. Lighting Fires, T. Charlton, London.
4723. Preventing Accumulation of Deposits, J. Demoulin, London.
4724. Boilers, H. F. Phillips, London.
4725. Filtering Apparatus, W. L. Wise.—(*Solvay et Cie., Belgium.*)
4726. Brake Apparatus, F. Platt, London.
4727. Inflating Pneumatic Tires, E. C. Peck, Old Charlton.
4728. Locking Device for Foot Brakes, A. Hardie, West Brighton.

3rd March, 1896.

4729. Learning Bicycle Riding, F. Hutchins, London.
4730. Attachment of Tires to Wheels, H. Godsal, London.
4731. Folding Writing Desk, W. C. Haigh, Manchester.
4732. Horseshoes, R. Robinson, Southampton.
4733. New Power for Driving Vehicles, W. J. Howcroft, Lye, near Stourbridge.
4734. Speaking Tubes, C. Darrah, sen., and A. Y. Reynard, Manchester.
4735. Valve for Pumps, J. Corbett and V. J. Bain, Glasgow.
4736. Vapour-pressure Motors, J. Murrie, Glasgow.
4737. Needle Threaders, J. Darling and T. Clarke, Glasgow.
4738. Washer for Lids of Churns, &c., E. B. Raper, York.
4739. Railway Coupling, W. A. Green, Aberystwyth.
4740. Metal Mouth Protector for Muzzles, W. F. and A. Weightman, London.
4741. Flying Machine, S. Dalziel, London.
4742. Railway Trucks, E. Rykovskoff, London.
4743. Nitrites of Soda and Potash, L. G. Paul, London.
4744. Stoppers for Bottles, E. Scholes and W. Hancock, Manchester.
4745. Moderator Petroleum Lamps, C. L. Charlopin, Manchester.
4746. Combined Steam Engines, &c., W. Schmidt, Birmingham.
4747. Rotary Cutter Heads, S. J. Shimer, Manchester.
4748. Arc Lamp for Optical Lanterns, &c., A. J. Beaumont, York.
4749. Purses, G. Wilkins, Kent.
4750. Fire-extinguishing Apparatus, W. Miller, Glasgow.
4751. Holder for Ring Spindles, J. W. Nasmith, Manchester.
4752. Appliance for Feeding Calves, E. A. Elliott, London.
4753. Pneumatic Tires, W. G. Wrench, Glasgow.
4754. Pumps, T. Owen, Liverpool.
4755. Inflating Valve for Tires, A. Wainwright, Leeds.
4756. Grate Bars for Boilers, B. A. Thomas, Staffordshire.
4757. Explosive Engine, T. Duffy and T. W. Newey, Birmingham.
4758. Holder, F. H. and H. Barwell, H. P. Kimberley, and J. F. Smith, Birmingham.
4759. Means for Transmitting Motion, G. Percival, Cork.
4760. Speech Instrument, E. Mulliner, Southport.
4761. Device for Fixing Lamps, F. H. Coulson, London.
4762. Hatching Chickens by Heat, R. Clark, Durham.
4763. Fostermother for Rearing Chickens, R. Clark, Durham.
4764. Driving Mechanism for Toys, C. E. Gyngell, London.
4765. Potato Diggers, J. Colquhoun, Glasgow.
4766. Compound Gas Engine, C. H. T. Alston, Glasgow.
4767. Hooks for Suspending Pictures, E. E. Cohen, London.
4768. Apparatus for Sorting Coinage, H. Broadbent, London.
4769. Pistols, H. S. Atkinson, Birmingham.
4770. Curtain Holder, T. Whittingham, Manchester.
4771. Driving Gear of Bicycles, J. E. Edwards, London.
4772. Pneumatic Tires for Cycles, W. T. Robbins, London.
4773. Electric Traction, J. Claret and O. Vuilleumier, London.
4774. Electrical Circuits, C. B. Callow and H. Bevis, London.
4775. Portable Railway Appliances, R. H. Courtenay, London.
4776. Furnaces for Heating Metal, W. H. Bailey, London.
4777. Cotton Seed Delinters, F. W. Cross, London.
4778. Method of Obtaining Electricity, B. F. da Motta, London.
4779. Double Flange Pan, W. R. Burridge, Portsmouth.
4780. Telescopic Vapour Flue, W. R. Burridge, Portsmouth.
4781. Recording Signals upon Locomotives, J. A. Meunier and Count M. G. de Bengy-Puyvallée, London.
4782. Cardboard Box Making Machine, A. Godfrey, London.
4783. Trousers, J. Meiklejohn and H. O. Tiarks, London.
4784. Mechanical Fog Signal, A. M. Cowley, Hackbridge, Surrey.
4785. Stirring Apparatus, A. Berger—*née* Andreae—London.
4786. Bottle Washing Machines, M. Donally, London.
4787. Gaiters or Leggings, O. Seefels, London.
4788. Converting Carbon into Electrical Energy, W. W. Jacques, London.
4789. Apparatus for Churning Milk, &c., J. Taylor, London.
4790. Lamps, W. Weickart, London.
4791. Harness, F. W. Billings, London.
4792. Heated Drying Cylinders, G. and R. Jagenburg, London.
4793. Card Holder, C. A. Dines, London.
4794. Holders for Conveying Ammunition, L. Silverman, London.
4795. Fire-boxes for Steam Boilers, E. Gentilini, London.
4796. Pencil Case and Sharpener, E. E. Monroe, London.
4797. Securing Hats, E. R. Standfield and W. Brew, London.
4798. Handle-bar Posts for Cycles, H. H. Lake.—(*J. P. Lovell Arms Company, United States.*)
4799. Opening and Closing Windows, J. Taylor, Manchester.
4800. Hair Brushes, H. H. Lake.—(*Florence Manufacturing Company, United States.*)
4801. Coupling Devices for Bicycles, W. W. Tucker, London.
4802. Spring Roller Bearings for Shaft Hangers, J. W. Hyatt, London.
4803. Lamps or Lanterns for Use on Vehicles, &c., B. E. P. Creighton, G. Story, and S. M. Barber, London.
4804. Thrust Bearings, F. Mossberg, London.
4805. Method of Magnetic Separation, J. P. Wetherill, London.
4806. Magnetic Separators, J. P. Wetherill, London.
4807. Electric Generators, J. Devonshire.—(*E. Thomson, United States.*)
4808. Safety Appliances for Brakes, J. Devonshire.—(*W. B. Potter, United States.*)
4809. Oil Port Lids of Axle-boxes, C. Erdbrink, London.
4810 Golf Clubs, R. Hunter, London.
4811. Means for Securing Jewellery, P. Wolfers, London.
4812. Withdrawing Beer from Casks, A. G. Hopkins, London.
4813. Type-writers, A. Winrow and F. A. Sanders, London.
4814. Safes, J. E. A. Greatorex, London.
4815. Estimating Distances, H. Trietsch and H. Berghaus, London.
4816. Stoppering Devices, J. D. Midson and F. W. Schroeder, London.
4817. Mechanism for Electric Arc Lamps, E. Lavens, London.
4818. Perforated Plates for Strainers, N. Heid, London.
4819. Ladies' Boas and Fur Collars, M. Rabe, London.
4820. Malting Grain, F. W. Golby.—(*J. Jungbluth, Germany.*)
4821. Fare Indicator, W. P. Thompson.—(*C. F. Kindermann and Co., Germany.*)
4822. Sliding Window Sashes, S. B. Cottrell, Liverpool.
4823. Vaporiser, M. Horwitz, Liverpool.
4824. Car Trucks, E. Peckham, London.
4825. Coffins, H. M. Handshy and S. L. Hain, London.
4826. Heating Water, J. S. Coe, London.
4827. Cartridge, P. A. Newton.—(*G. B. Reetz and W. M. Cooper, Australia.*)
4828. Cooling Water, P. A. Newton.—(*C. C. Worthington, United States.*)
4829. Advertising Bottled Goods, T. Heffernan, London.
4830. Cigar Moistening Device, F. J. Measures and F. Adams, London.
4831. Piston-rods, A. J. Boult.—(*R. J. Muller, United States.*)
4832. Straightening Contracted Joints, K. R. Schramm, London.
4833. Cutting Files, J. Blakey and W. Backhouse, London.
4834. Cycle Frames, Fitz-Hardinge R. B. Liebenrood, London.
4835. Shells, E. M. Johnson, London.
4836. Button, A. J. Boult.—(*O. W. Ketchum and E. A. Griffith, United States.*)
4837. Circuit Closers for Electric Bells, J. Newton, London.
4838. Preventing Refilling of Bottles, A. Guattari, London.
4839. Mechanical Milking Machine, C. B. Stróyberg, London.
4840. Index Cutting and Printing Machine, W. Corfe, Liverpool.
4841. Exhibiting Pictures, J. Y. Johnson.—(*W. Latham, United States.*)
4842. Valve Sprinkler, W. S. Stallybrass and W. Lewis, London.
4843. Thermoscopes, A. P. Harland, F. M. Wright, and D. A. Usina, London.
4844. Lamps, T. E. Adams, London.
4845. Lamps, T. E. Adams, London.
4846. Steam and Hot-water Boilers, J. Plenty, London.
4847. Boilers, E. Montier, London.
4848. Starting Gear of Tramcars, J. W. Howe and H. J. Jordan, London.

4th March, 1896.

4849. Brakes, O. H. Rieths, London.
4850. Fenders, C. E. Elfström, London.
4851. Bottles, E. Eberle, London.
4852. Hangers for Sad Iron, &c., G. H. Wagner, London.
4853. Valves, H. W. Carr, London.
4854. Skimmers, R. S. Schmidt, London.
4855. Tool, C. S. Vidor, London.
4856. Signal System, H. Schneider, London.
4857. Axle, H. Noelte, London.
4858. Sweetmeat Figures, R. Berger, London.
4859. Adjustment of Cycle Chains, R. J. Alpe and J. Wilkinson, Birmingham.
4860. Short Action Horse Rake, H. Cook, Gloucestershire.
4861. Mandril, F. Thiemicke, Leeds.
4862. Portable Cooking Apparatus, F. A. Wallis, Basingstoke.
4863. Compasses, A. W. Bevis, Birmingham.
4864. Electric Motors for Tramway Cars, F. M. Lewis, Leeds.
4865. Carding of Studs, &c., T. Morton, Birmingham.
4866. Driving and Spinning Frames, F. Prestwich, Manchester.
4867. Preventing Breaking of Busks, W. T. Pretty, Ipswich.
4868. Valves, W. Cameron and J. Cochrane, Barrhead, near Glasgow.
4869. Sleeve and other Links, G. F. Spittle, Birmingham.
4870. Forming Electrical Connection, A. Denny and J. Kempton, Dumbarton.
4871. Securing Tires to Wheels, S. Austin and A. Farnhill, Manchester.
4872. Buildings, G. Nicholls, Leicester.
4873. Valve, F. Farnworth, Ramsbottom, near Manchester.
4874. Machines for Treating Flax, A. Spiegelberg, Glasgow.
4875. Measuring and Self-registering Taps, J. Mowat, Glasgow.
4876. Chairs, A. Plant, Glasgow.
4877. Guiding Textile Fabrics, J., H. C., and W. Dalglish, Glasgow.
4878. Lace Tags, J. Smith, Manchester.
4879. Spinning Tackle for Fishing, S. Allcock.—(*A. Hintze, Russia.*)
4880. Pug Mills, T. C. Fawcett and T. C. Fawcett, Ld., Halifax.
4881. Corset Stiffeners, A. Bürger, Barmen, Germany.
4882. Holding Labels and the like, A. G. Hebblethwaite, Halifax.
4883. Reversing Motion, A. Roberts and H. Roberts, Southport.
4884. Two-bladed Bread Cutter, H. Brown, Bradford.
4885. Three-bladed Bread Cutter, H. Brown, Bradford.
4886. Rotary Kick-ups or Tipplers, J. J. Prest, Newcastle-on-Tyne.
4887. Gloves, H. Harris, Norwich.
4888. Oven Door Light, C. Skill and P. J. Skill, Nottingham.
4889. Wearing Parts of Ploughs, W. S. Richmond, Suffolk.
4890. Fixing Mordants on Fibres, A. Ashworth, Bury.
4891. Removing Wrappers, R. J. Minns and W. H. Jones, Liverpool.
4892. Built Columns, Beams, and Girders, J. A. Main, Glasgow.
4893. Pneumatic Tires, P. MacLellan and J. W. O. Walker, Glasgow.
4894. Discharge of Water from Flushing Tank, J. Jobbins, Somerset.
4895. Castors, A. E. Inman, Glasgow.
4896. Ball Castor, J. McMurray and J. C. McGavin, Kilmarnock.
4897. Chest Protector for Cyclists, S. D. Sykes, Leeds.
4898. Door Fastenings, J. Astbury and H. Vincent, Birmingham.
4899. Alloys, J. C. Bull, London.
4900. Paper Boxes, W. Love, London.
4901. Covers for Books, L. H. Bliss, London.

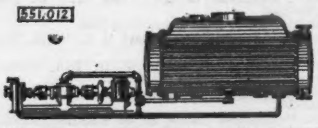
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

551,012. Method of Cleaning Surface Condensers, *E. Tweedy and T. Saunders, Danbury, Conn.—Filed March 26th*, 1894.

Claim.—The method of removing the deposit from the condensing surfaces in condensers without dismantling the same, which consists in introducing into the condenser which is to be cleaned, a liquid which is a solvent of one or more of the oleaginous, pitchy, or gummy binding components of said deposit, and in violently agitating said liquid by forcing a gas into the liquid in the condenser between the surfaces to be cleaned, thereby forming a partial solution and a partial mixture of the ingredients of said deposit with said liquid, and causing said solution and mixture to abrade said deposit, and in withdrawing the resulting fluid from the condenser without removing the surfaces cleaned, substantially as specified.

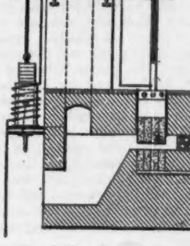
551,012



551,014. Electric Smelting Furnace, *J. A. Vincent, Philadelphia, Pa.—Filed July 18th*, 1895.

Claim.—(1) In an electric furnace, the combination of a substantially horizontal channel way for supporting the material to be smelted, two electrodes of different polarity arranged transversely to said channel way, a positively acting feeding device arranged to force the material to be treated into the channel way at one end and between the electrodes, and a discharging pit arranged at the opposite end of the channel way and opening into it. (2) In an electric smelting furnace, the combination of a substantially horizontal channel way for supporting the material to be smelted, two electrodes arranged in said channel way and constituting a part of the walls thereof, means to feed the electrodes relatively one to the other to compensate for consumption thereof and maintain them as boundary walls of the channel way, a positively acting feeding device, consisting of a screw for feeding the materials to be smelted through the channel way and between the electrodes, a hopper for containing said materials and delivering them to the feeding screw, a discharge opening from the channel way, a chimney flue to carry off the products of combustion and vaporisation, and automatic electrically-controlled devices for regulating the means for feeding the electrodes relatively one to the other.

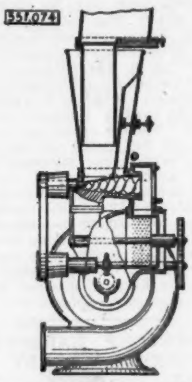
551,014



551,074. Feeding Appliance for Coal-dust, *F. de Camp, Berlin, Germany.—Filed August 27th*, 1895.

Claim.—(1) A perforated rotary distributing drum in combination with means of supplying coal-dust to its periphery, and a ventilating device operating in its interior space to mix the said dust with air and transfer it to a combustion chamber, substantially as set forth. (2) In combination with a hopper, the hinged plate *n* arranged on one side of its interior, the adjusting screw *o* acting on the said plate to control the discharge, and a conical screw conveyor having its smaller end arranged under the outlet of the said hopper, substantially as set forth.

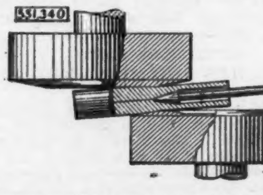
551,074



551,340. Mechanism for Making Tubes from Metallic Ingots, *R. C. Stiefel, Ellwood, Pa.—Filed October 10th*, 1895.

Claim.—(1) The combination of two parallel discs revolving in the same direction and overlapping each other, one of said discs being bevelled at its outer edge, which bevelled surface is opposed to a portion of the plane surface of the outer disc; the outer diameter of this plane surface and the inner diameter of the bevelled surface opposed to it being substantially the same and the edges formed by both diameters intersecting the same transverse plane through the pass between the discs; the angles of the opposing surfaces converging to this plane which is at the narrowest part of the pass, with a conical mandrel lying in the axis of the pass at its exit side, substantially as set forth. (2) The combination of two parallel discs revolving in the same direction, bevelled at the edges of their adjacent faces and overlapping each other so that the bevelled portion of one disc lies opposite a flat portion of the outer disc, the edges formed by the smaller diameters of the bevelled portions of the discs intersecting the same transverse plane through the pass between the disc whereby the sides of the pass first converge to this plane and then diverge beyond it, with a piercing mandrel located between the diverging sides of the pass and exactly in axial line of the pass, substantially as hereinbefore set forth.

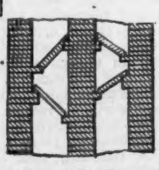
551,340



551,390. Cement Kiln, *F. M. Lande, New York, N.Y.—Filed February 16th*, 1895.

Claim.—(1) A kiln for the purpose described having one or more chambers, each chamber having a series of removable, adjustable shelves, said shelves extending from side to side of the chamber and provided with supporting lugs and openings formed by the lugs, as and for the purpose set forth. (2) A kiln having a series of shelves inclined to each other, said shelves having lugs and openings at their lower edges as and for the purpose set forth. (3) A kiln the inner walls of which have supported ledges for deflecting shelves, the upper side of the alternate ledges being removable to give said shelves an adjustable inclination, as and for the purpose set forth.

551,390



NAVAL ARCHITECTURE.—A FEW PRINCIPLES POPULARLY EXPLAINED.

No. IV.—STABILITY.

FROM the preceding papers it will have become evident that the vertical position of the centre of gravity of a ship and her cargo are of the greatest importance in the determination of her stability. It will also be easily understood that the "trim" of a vessel, or, in other words, her relative depth of immersion at the bow and stern, are influenced by the longitudinal position of the same point.

Let us now consider how the position of the centre of gravity is determined:—First, vertically; and second, longitudinally.

To ascertain the vertical distance of the centre of gravity of a ship, either from the underside of her keel or some other fixed position, we may proceed either by calculation or by experiment. The former method is the only possible one when preparing a design upon which a ship is to be built; the latter is possible only after the vessel is built and afloat. The method by calculation is open to the chances of error in regard to estimates made of the weights of the thousand-and-one items which constitute her hull and equipment, to say nothing of the constituents of her lading. But the method by experiment gives a result which is absolutely exact. Nevertheless, the method by calculation must be resorted to in designing a ship of war, especially an armour-clad, for in such vessels it is not possible afterwards to modify the position of the centre of gravity by the stowage of cargo, as in a mercantile vessel, seeing that the cargo of a ship of war consists of guns, armour plates, coals, stores, &c., the positions of which are fixed in the original design. A mercantile vessel may be unstable without her cargo, and require ballast to keep her upright when her cargo is discharged, but a modern ship of war must carry as much offensive and defensive material as possible on her displacement, and therefore has no margin for ballast. She must, in fact, be sufficiently stable as designed, and not have an excess of stability so as to cause her to roll seriously. Hence the position of her centre of gravity must be known before she is commenced to be built, and the position must be known to be a suitable one. The centre of gravity of a ship of war is therefore determined by calculation in preparing her design, and its position is afterwards verified by experiment when she is ready for sea. So carefully are these calculations made at the Admiralty office, that errors of any magnitude are rarely discovered when the vessel is built.

To ascertain by calculation the vertical position of the centre of gravity, it is usual to make the underside of keel the axis about which the moments of leverage of the materials composing the hull and equipment are calculated. It is impossible within the limits of these elementary articles to explain in detail how the weights of the several parts of the vessel are determined, or how the centre of gravity of each item is found. The way to go about each element will readily suggest itself to the average arithmetician. Suffice it to say, that by increasing the number of items the size of each is thereby diminished, and with the multitude of small calculations, it is found that small mistakes in one direction are balanced by other small mistakes in an opposite direction, and the total usually comes very near the truth.

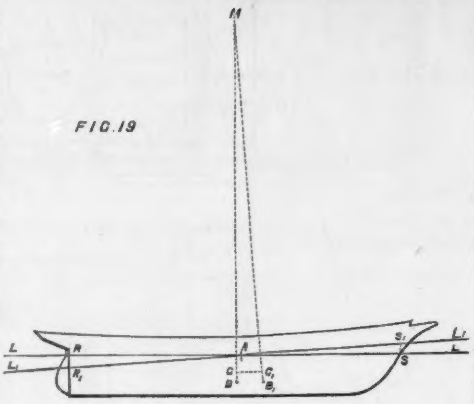
The general course of procedure is to multiply the calculated weight of each item of hull and equipment by the distance of its measured centre of gravity above the underside of keel; the product in each case gives the moment of leverage of the said item about the underside of keel as a fulcrum. The sum of the products divided by the sum of the weights gives us the height of the centre of gravity of the entire vessel above the underside of the keel.

For the longitudinal position of the centre of gravity measurements are usually taken from the plane of the midship section, or at the middle of the vessel's length. All items on the fore side of the midship section give forward moments of leverage, and all on the aft side of the midship section give after moments of leverage. The course of procedure is to multiply the weight of each element on the fore side of the midship section by the measured longitudinal distance of its centre of gravity from the midship section; and each element on the after side of the midship section by the longitudinal distance of its centre of gravity from the midship section. If the sums of these two sets of products are equal it shows that the centre of gravity of the vessel is at her midship section, or at the middle of her length. But if one is in excess of the other, as is usually the case, then the difference between them is divided by the total weight, the result being the distance of the centre of gravity either before or abaft the midship section, according to whether the excess of moment of leverage is before or abaft that plane.

When we have found the longitudinal position of the centre of gravity we have also the longitudinal position of the centre of buoyancy—for the vessel will not float in equilibrium until these points are in the same vertical plane. Hence, if the longitudinal position of the centre of gravity as calculated does not correspond with the longitudinal position of the centre of buoyancy at the designed trim of the vessel—that is to say, at the designed load water-line—some of the weights in the vessel must be shifted until the desired correspondence occurs.

In Fig. 19, L L is the designed load water-line of a vessel having a displacement in tons D. The centre of buoyancy in that condition is B and the centre of gravity is G. Suppose that a weight P already in the vessel is moved through a distance d towards the bow, thereby altering the load water-line to L_1 L_1. Let M be the position of the longitudinal metacentre at a moderate angle of inclination, such as that between the lines L L and L_1 L_1. Suppose G_1 the altered longitudinal position of the centre of gravity of the vessel due to moving the weight P through the distance D. Join M G_1, then B_1, the altered position of the centre of buoyancy, will be in the line M G_1 produced. Moreover, M B_1 is perpendicular to L_1 L_1, for M is actually the intersection of perpendiculars through B and B_1 to their respective water-lines.

FIG. 19



Let S S_1 be the alteration of trim at the stem and R R_1 at the stern post.

From the statical law mentioned in preceding papers

$$P \times d = D \times G\,G_1$$

and

$$G\,G_1 = \frac{P \times d}{D}$$

The angle of inclination being small, A the axis of intersection of the two water planes will approximately correspond with the centre of gravity of the load water plane—a point usually determined when making the displacement, &c., calculations.

Suppose a foot and a ton to be the units of measurement and weight. Then referring to Fig. 19, it is obvious that the angles R A R_1, S A S_1, and G M G_1 are equal.

And

$$\frac{A\,R}{R\,R_1} = \frac{A\,S}{S\,S_1} = \frac{M\,G}{G\,G_1}$$

$$\therefore \frac{A\,R + A\,S}{R\,R_1 + S\,S_1} = \frac{R\,S}{R\,R_1 + S\,S_1} = \frac{M\,G}{G\,G_1}$$

But

$$G\,G_1 = \frac{P \times d}{D}$$

Hence

$$\frac{R\,S}{R\,R_1 + S\,S_1} = \frac{M\,G \times D}{P \times d}$$

$$R\,R_1 + S\,S_1 = \frac{R\,S\,(P \times d)}{M\,G \times D}$$

But all the terms on the right-hand side of this equation are known, and consequently the sum of R R_1 and S S_1, which is the total alteration of trim due to shifting the weight P, is also determined.

To find the separate values of R R_1 and S S_1:—

$$A\,R : A\,S :: R\,R_1 : S\,S_1$$

$$\frac{A\,S}{A\,R + A\,S} = \frac{S\,S_1}{R\,R_1 + S\,S_1}$$

$$\frac{A\,S}{R\,S} = \frac{S\,S_1}{R\,R_1 + S\,S_1}$$

But

$$R\,R_1 + S\,S_1 = \frac{R\,S\,(P \times d)}{M\,G \times D}$$

$$\therefore \frac{A\,S}{R\,S} = \frac{S\,S_1\,(M\,G \times D)}{R\,S\,(P \times d)}$$

Hence

$$S\,S_1 = \frac{A\,S\,(P \times d)}{M\,G \times D}$$

Similarly

$$R\,R_1 = \frac{A\,R\,(P \times d)}{M\,G \times D}$$

But, as already remarked, the lengths of A S and A R are shown on the ordinary displacement, &c., calculation, and consequently the values of S S_1 and R R_1 are fully determined.

Suppose A to be at the middle of the length of the load water-line, so that A S = A R = ½ S R.

$$\text{Then } S\,S_1 = R\,R_1 = \frac{S\,R\,(P \times d)}{2\,M\,G \times D}$$

In this way is the alteration of trim due to moving a weight in a fore-and-aft direction on board a vessel determined.

It is customary to calculate the moment of leverage required to alter the trim one inch, and the result so obtained is practically correct, if used to obtain the moments for alterations up to even a foot.

In this case R R_1 + S S_1 = $\frac{1}{12}$ foot, and the equation

$$\frac{R\,S}{R\,R_1 + S\,S_1} = \frac{M\,G \times D}{P \times d}$$

becomes

$$P \times d = \frac{M\,G \times D}{12\,R\,S}$$

By substituting the values of M G, D and R S for any particular vessel, the moment P × d, required to alter the trim one inch, is at once known.

If P be in tons,

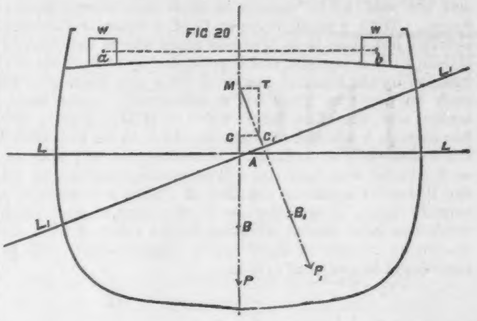
$$d = \frac{M\,G \times D}{P \times 12\,R\,S}$$

gives the distance that one ton must be moved in a longitudinal direction to alter the trim 1in., or, in other words, to increase the immersion about ½in. at one extremity of the vessel, and diminish it by about ½in. at the other extremity.

Let us now consider the experimental method of determining the vertical height of the centre of gravity. But before doing so it is perhaps desirable to remark that the longitudinal position of that point is known from the fact that it must be in the same transverse plane section as the centre of buoyancy; the plane section being, of course, perpendicular to the load water plane of the vessel at that time. Hence, when we have calculated the longitudinal position of the centre of buoyancy at any draught of water and trim by the method described in a preceding paper, we have found the longitudinal position of the centre of gravity also. This is, in fact, the experimental method of finding the position of the centre of gravity in a fore-and-aft direction after a vessel is built, afloat, and loaded.

For the vertical position:—Turning to Fig. 20, L L is the upright water-line and L_1 L_1 is the water-line when the vessel has been heeled through an angle—purposely exaggerated for the sake of clearness—due to moving a weight of a few tons from one side of the deck to the other.

FIG 20



The statical principle upon which is based the experimental method about to be described is that already referred to in the course of these papers—viz.: "If the centre of gravity of any part of a body be shifted in a given direction through a given distance, the centre of gravity of the whole body is shifted in a parallel direction through a distance smaller than the given distance, in the same proportion that the weight of the shifted part is smaller than the weight of the whole body."

Let M represent the transverse metacentre corresponding to a small angle of heel. M P is the upright axis; and consequently G, the centre of gravity, is somewhere in that line. It is required to find the distance of G below M.

Let a be the centre of gravity of a heavy body, or group of heavy bodies, of weight W resting on one side of the deck of the vessel when she is upright; and let that body, or group of bodies, be now shifted across the deck to the opposite side of the vessel, so that b is now the position of the centre of gravity of the weight W. The shifting of this weight causes the vessel to heel over to a certain angle, which is easily measured by means of a plumb line hanging through the nearest hatchway. Let P M P_1 be that angle, so that the centre of gravity of the vessel will now be in the new vertical line M P_1. Let the total weight of the vessel—that is to say, her displacement—be D.

Through M draw M T parallel to $a\,b$, and of such a length that

$$M\,T : a\,b :: W : D.$$

Through T draw T G_1 parallel to M G, intersecting M P_1 at the point G_1.

Then G_1 will be the new position of the centre of gravity. Through G_1 draw G_1 G parallel to $a\,b$, then G will be the position of the original centre of gravity of the vessel when upright.

For since M T : $a\,b$ :: W : D, therefore M T is the distance parallel to $a\,b$, through which the centre of gravity of the total weight D of the vessel is moved by shifting the weight W through the distance $a\,b$.

Also

$$\frac{M\,T}{a\,b} = \frac{W}{D}$$

$$\therefore M\,T = \frac{W}{D} \times a\,b$$

But

$$G\,G_1 = M\,T.$$

Hence

$$G\,G_1 = \frac{W}{D} \times a\,b$$

Since

$$M\,G = G\,G_1 \cot P\,M\,P_1$$

$$\therefore M\,G = \frac{W}{D} \times a\,b \times \cot P\,M\,P_1$$

Hence as W_1, D_1, $a\,b$, and the angle P M P_1 are all known, therefore M G is also determined.

In performing this experiment it is important that the vessel should be floating steadily in still water, and that the weather should be calm. If there are any portions of the vessel or her lading absent or shifted out of their true position at the time of the experiment, exact account should be taken of them and allowance afterwards made. It is also important that loose weights on board should be secured, and all water carefully pumped out of limbers, bilges, and ballast tanks. To ensure accuracy it is usual to measure the inclination of the vessel by plumb lines at fore, main, and after hatchways, and the mean inclination is used in the calculation. Pig iron ballast or cast iron blocks of equal and known weight—say 56 lb. or 112 lb.—are most convenient for making this experiment. A total weight of from 5 tons to 10 tons is quite sufficient for making the inclining experiment in an ordinary mercantile vessel, but a much heavier shifting weight is, of course, necessary when experimenting with a large armour-clad.

Usually, a weight of about 5 tons is placed on each side of the deck, so as to bring the vessel on an even keel at starting. Then the weight on one side is moved over to the other side, and the angle measured with the entire weight on that side. Afterwards the entire weight is transferred back to the opposite side, and the angle again measured. The mean of the two experiments is used for determining the position of G.

The method by experiment, as already seen, furnishes us with the distance of the centre of gravity below the metacentre at the angle of inclination due to the shifted weight. As that angle is not very great—only a few degrees—the metacentre may be considered as the fixed point referred to in Article No. II. of this series. The distance between the points M and G thus found is usually spoken of as the G M of the vessel, and it furnishes the naval architect with a very excellent criterion of her stability and rolling qualities. A large value of G M in the upright position implies a high initial stability, and, therefore, a strong righting tendency when the vessel is inclined from that position by a passing wave. Hence vessels with a large G M are quick rollers, and are said to be uneasy in their movements among waves. With a small value of G M a vessel rolls more slowly; but then if G M is too small she is deficient in stability when upright, and if propelled by sails, is readily inclined by the force of the wind until she leans over to such an angle as gives her a sufficiently higher metacentre, and, therefore, larger value of G M. Unless she has enough freeboard to allow her deck to be still above the water when so inclined, the metacentre will not rise as she heels over, and she will ultimately capsize, as did the ill-fated Captain in the Bay of Biscay a quarter of a century ago. It was the loss of that ship of war which tended to draw special attention to the value of what are known as curves of stability, a subject which will be considered in our next article.

ST. PANCRAS ELECTRIC LIGHTING.

THE KING'S-ROAD REFUSE DESTRUCTOR AND ELECTRIC LIGHTING STATION.

(*Concluded from page* 259.)

THE boiler house is built partly on the top of the tank and partly on brick piers placed between pairs of destructor cells—see Figs. 5, 6, and 8. A roadway 16ft. wide, with 9ft. headway, passes under the whole length of the boiler house at the destructor yard level, and affords access to the front of the six cells arranged on one side. The interior of the boiler house measures about 60ft. by 52ft., and is 27ft. high from the roof ties to the floor, which is 13ft. above the roadway underneath. From the bottom of the tank to the ridge of the roof is 63ft. The house is laid out for five boilers and an economiser. At present there are three Lancashire boilers and an economiser. The boilers were supplied by Messrs. Easton, Anderson, and Goolden. They are 30ft. long and 7ft. 6in. in diameter, with two flues 3ft. diameter, with six tapering cross tubes in each, and are designed for a working pressure of 125 lb. per square inch, and a test pressure—hydraulic—of 180 lb. per square inch. The shell is of steel plates $\frac{3}{4}\frac{1}{4}$in. thick, and the flues have Adamson ring joints. The setting of the boilers is peculiar, and will be understood by reference to Figs. 8 and 9. The boilers are supported on cast iron saddles resting on brickwork near the front and on cross joists suspended from the top flanges of the girders over the roadway at the back end to allow for expansion in that direction. The whole of the outside shell below the water line is exposed to one large flue—Fig. 9—thus affording the largest possible effective heating surface, ready facility for inspecting every rivet, and a reduction in the resistance to the passage of the gases. It also enables the boilers to be placed much nearer together than in the ordinary Lancashire setting—they are spaced 10ft. centre to centre—and the main flue to the chimney to be placed underneath the boilers instead of at the end. The space occupied is therefore greatly reduced without impairing the efficiency of the boilers. Careful tests have proved that the idea of any advantage being gained by passing the gases up and down the outside shell is an entire fallacy. The following are the results of the official trial of one of these boilers carried out on September 25th, 1895. A preliminary trial gave almost identical results:—

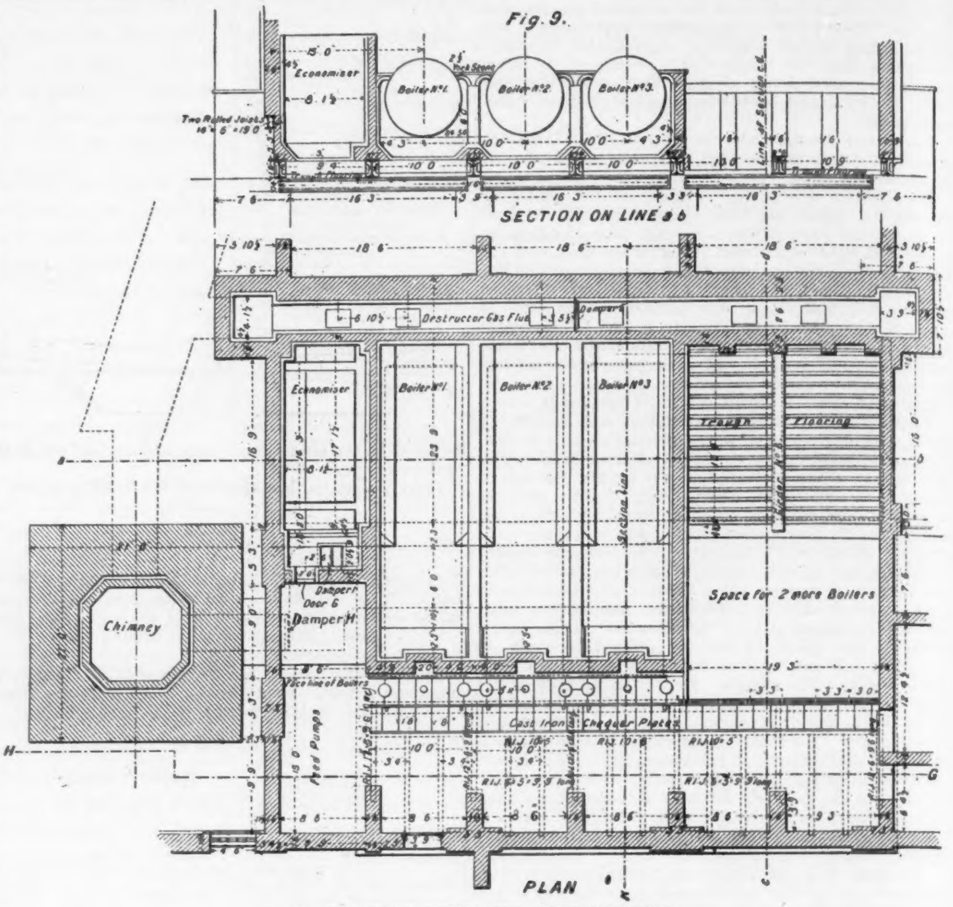
Boiler Trial, September 25th, 1895.

Data.—	
Area of heating surface	1000 sq. ft.
Area of fire-grate	22·5 sq. ft.
Ratio $\frac{\text{heating surface}}{\text{grate surface}}$	44·4
Coal used, best Welsh steam coal.	
Observations.—	
Duration of trial, 8½ hours, from which a period of 5½ hours was selected, giving the most uniform conditions of working. The following figures relate to the 5½ hour period (11.45 a.m. to 5.15 p.m.)	
Mean pressure of steam above atmosphere per square inch	123 lb.
Corresponding temperature	351·8 deg. Fah.
Mean temperature of feed	92·4 deg. Fah.
Total water evaporated	29,500 lb.
Total water evaporated per hour	5363 lb.
Total coal used	2925 lb.
Total coal used per hour	531·8 lb.
Number of times fires were stoked per hour	7
Average temperature of gases at back end of boiler flue	925 deg. Fah.
Ditto at front end (passing to chimney)	435 deg. Fah.
Average fall of temperature of gases passing along flue outside boiler	490 deg. Fah.
Principal Results.—	
Pounds of coal burned per square foot of grate per hour	23·6 lb.
Ditto per square foot of heating surface	0·532 lb.
Thermal units transmitted per square foot of heating surface per hour	6049
Amount of feed-water per lb. of coal	10·08 lb.
Equivalent water evaporated per lb. of coal from and at 212 deg. Fah.	11·76 lb.
Water evaporated per square foot of heating surface per hour	5·363 lb.
Equivalent water evaporated per square foot of heating surface from and at 212 deg. Fah.	6·262

Fig. 10 is a diagram showing the results observed throughout the trial. It will be noticed that the temperature of the gases passing away to the chimney was very much more uniform than at the back end of the boiler, and that there was always a large drop in the temperature of the gases passing along the outside flue, showing that the single flue does its duty remarkably well. The temperature at the back end was observed by means of a Schaffer and Budenberg mercury thalpotasimeter, and at the front end by a pyrometer made by the same firm. There are very few Lancashire boiler tests published which give efficiencies surpassing this case, and if the high rate of heat transmission—6049 units per square foot per hour—is taken into account, but few other tests could compare with it.

As to the dryness of the steam, no direct test was applied, but an indication of the dryness was afforded by the running with part of the steam, and at 350 revolutions per minute, a 200-horse power Belliss engine with no load. The engine ran silently throughout the whole of the test, with all the drain cocks closed. If the steam had been at all abnormally wet the presence of water in the cylinders would undoubtedly have been noticed, as the engine was watched for that purpose.

Fig. 9.



PLAN OF BOILER HOUSE AND BOILER SETTING

The boilers have been found to be capable of evaporating over 7000 lb. of water per hour when forced. The destructor gases—which can be applied to the boilers by opening valves at the back ends—pass along the large outside flue and also through the two internal flues passing out of the furnaces to 15in. diameter down pipes leading to the chimney. The furnaces and ashpits are provided with air-tight doors, to be closed when the gases are being used, and the down pipes have valves to be closed when the coal fires are in use. Grid dampers are provided at the back ends of the internal flues for regulating the draught to the coal fires while the destructor gases are allowed to pass under the boiler only. Another damper is provided at the outlet to the main flue leading to the chimney. A feature in the design of all the flues is the provision of large areas and pockets to collect the fine dust which is blown through from the destructors.

On one side of the battery of boilers is fixed a Green economiser—see Fig. 9—containing 240 tubes, each 9ft. long and 4½in. external diameter, and giving a total heating surface of 2500 square feet. A capacious pocket is allowed under the pipes for the collection of dust thrown down by the scrapers. The scrapers are worked by a belt from a Goolden electric motor fixed on a gallery overhead. The economiser is heated

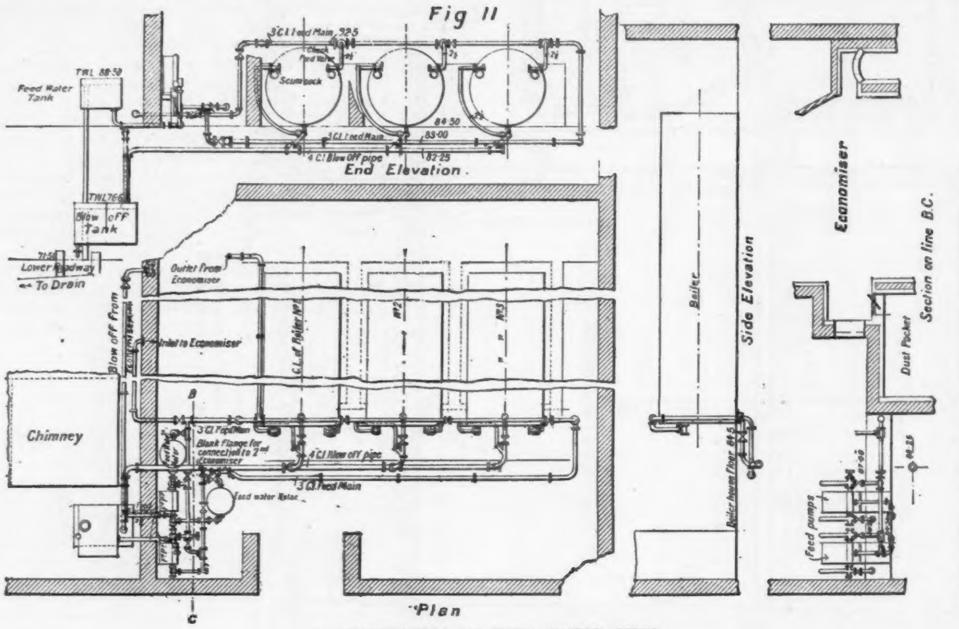
entirely by the destructor gases, and provision is made for drawing off steam if it is produced when the amount of feed-water passing to the boilers is small. The top collecting pipe is made large—6in. in diameter—and is carried up to a steam drum overhead, and a return circulating pipe is carried from this drum to join the water inlet pipe of the economiser. The steam drum has a gauge glass, a safety valve, and an outlet for steam, which is closed automatically by a float valve when the water rises above the centre line of the drum.



ARRANGEMENT OF FEED WATER PIPES

The outlet also has a stop valve with a small by-pass, and a reducing valve to prevent the delivery of steam at a pressure exceeding 125 lb. per square inch. The circulation of the water in the economiser takes place continuously and is very beneficial, as it mixes a stream of hot water with the cold feed and ensures a warm supply to the heated pipes, and thus guards against the danger of corrosion by reason of moisture condensing on the surface of the cooler ends of the pipes.

There are two vertical duplex feed pumps made by Messrs. Mumford and Co., of Colchester, each being capable of delivering 1500 gallons of water per hour against a pressure of 130 lb. per square inch, with steam at 125 lb. An injector, capable of delivering 1000 gallons per hour, is also fixed. The feed pipes are arranged in a ring, with two water meters, and suitable valves for providing duplicate ways to each boiler from each pump, as shown in Fig. 11.

There are two outlets from each boiler, 6in. in diameter, communicating to the two 7in. main steam pipes. The usual low-water alarms, safety valves, scum cocks, and other mountings are provided. Steam can be drawn from either main to supply the feed pumps or injector, and the two mains are coupled together at the further end of the engine-room to form a ring supply to the engines. The straight pipes are of wrought iron, the bends of solid drawn copper, and the T pieces cast iron. The joints are made with corrugated brass rings and red lead. There are no expansion joints, but the arrangement of bends and straight pieces is carefully planned to permit free expansion everywhere without injury. Fig. 12 shows the arrangement of the steam piping. Drains are provided at all the dead ends of the steam pipes in the boiler-house, and at large cast iron water pockets—see Fig. 12—on the mains in the engine-house close to the first branch supply pipe. Each engine is also provided with a separator. The steam pipe drains all lead to a pair of Royle steam traps—arranged in duplicate—which lift the condensed water back into the feed tank. By-pass pipes ½in. in diameter are provided for blowing through when the traps are out of order. The valves on the steam mains are Hopkinson's parallel slide valves with internal by-passes.

At the east end of the boiler-house there is an underground coal store into which the coal is shot from carts entering from King's-road, and is raised from the store to the boiler-house by a low-pressure hydraulic hoist, having a lift of 16ft. 6in. The feed-water for the boilers is drawn from the New River Companys' mains, and is softened before use by means of lime, in an apparatus supplied by Messrs. Doulton. The lime is thrown into a cylinder, kept full of water, and stirred by a revolving mixer operated by a water wheel turned by the hard water flowing into the supply cistern. The lime water and hard water flow together through a conical shoot into a 6000 gallon settling tank erected on the roof of the engine house; the softened water passing from an outlet near the surface of the water to a pair of filters in the boiler-house gallery. The filtering material is a layer of small wood shavings, held in position by a perforated iron grid, through which the water passes upwards, and then to the feed-water tank. Either filter can be used alone or both together. This apparatus reduces the hardness of the water from 16 deg. to 6 deg. or 7 deg.

The engine-house is shown in plan in Fig. 7, page 261, and in cross section in Figs. 14 and 17, pages 285 and 287. Fig. 16 shows the west side elevation. The main roof is carried on heavy cast iron stanchions, which have brackets supporting the rail bearers of a 5-ton overhead travelling crane. The width between the stanchions is 26ft., the height from floor to ceiling 22ft., and the length about 62ft. Behind the stanchions on the west side is a space containing the main switchboard, with a sloping skylight overhead, and on the east side a larger space for the condensing plant, testing-room, men's mess-room, &c., covered by a gallery on a level with the boiler-house floor for access to the main steam valves, &c., and containing an office for the resident engineer, overlooking the engine-room. Part of the building work on the east side is only temporary, as the engine-room will be extended in that direction in the future.

Space is available at present for five large engines, set out with centre lines 10ft. apart. The engine foundation is a mass of concrete, arched in the middle, to prevent the engine vibrations setting up a rocking action—Fig. 17, page 287—and carried down 9ft. at one end and 11ft. at the other to form walls to the basements, which extend along both sides of the house. The basement on the west side contains the rheostat and other regulating resistances, and affords access to the cables connecting from the switchboard to the dynamos and mains, &c. Ample space is provided for these purposes, and plenty of ventilation from an outside area and upwards through an opening in the floor extending all along the switchboard under a step. On the east side the basement contains the condensers and their water pipes, and also the exhaust steam pipes and drains leading to the steam traps. The whole of these pipes, as well as the bolts at their joints, are therefore readily accessible at any time without taking up the floor.

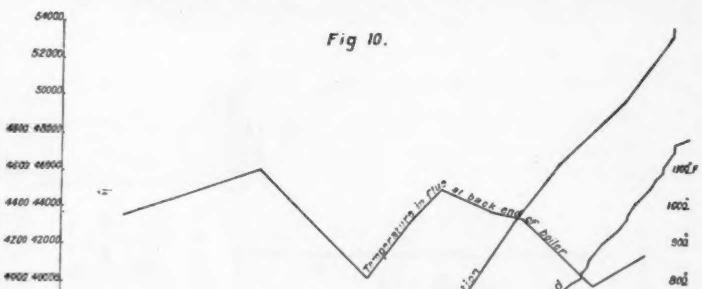


DIAGRAM OF RESULTS OF BOILER TRIALS

There are at present three sets of compound Belliss engines, each of about 200-horse power, with 12in. and 20in. cylinders by 12in. stroke, designed to run at a normal speed of 350 revolutions per minute. The working parts are wholly enclosed and lubricated by Belliss's force pump system. The engines are governed on the throttle valves. There are two dynamos to each engine, one at each end of the crank shaft, and direct coupled to the engine shaft. The dynamos are Crompton's shunt-wound two-pole undertype, with armatures having Crompton's patent hydraulic pressed twisted copper bars. Each machine is wound for a maximum load of 70,000 watts, a maximum current of 550 ampères, and a maximum pressure of 135 volts. The maximum current must be obtainable at a pressure of 112 to 127 volts. The maximum pressure must be obtainable with a current of 518 ampères. The official trial at Birmingham with a load of 133,000 watts showed a steam consumption of 19·84 lb. per electrical horse-power per hour working condensing.

Fig. 19, page 289, shows one of the engines with its pair of dynamos. The exhaust pipes from the engines are connected together by a 10in. main, running longitudinally in the east side basement, with stop valves between the engine branches. This 10in. main is connected to a 12in. vertical exhaust pipe 50ft. high through a stop valve, and also through a by-pass relief valve, to provide an outlet in case the vacuum fails at any time, and it is also connected to three condensers through stop valves and reflux valves. The condensers are of the "ejector" type, made by Messrs. Ledward and Co. They are supplied with water from an overhead tank of 6000 gallons capacity, and deliver into the large underground tank. The difference of level of the water in the two tanks is 25ft. One condenser is capable of serving one engine, and the other two are each capable of serving two engines running simultaneously. The feed pumps also exhaust into the condensers. The water to supply the condensers is drawn from the large underground tank, and pumped into the overhead tank or direct to the condensers by Gwynne centrifugal pumps, driven by Crompton series-wound electro-motors. There are three of these pumps designed to deliver 20,000 gallons per hour to a height of 25ft. The motor fields are wound on four limbs, and a switch is provided for placing all four windings in series, or two in series and two parallel. With the former arrangement the above-mentioned load is worked, and with the latter the speed and power is increased to enable the pumps to deliver 25,000 gallons per hour to a height of 40ft., to be distributed over the cooling apparatus. The current is supplied to the motors at 220 volts.

The pumps have two suction pipes and two delivery pipes—see Fig. 13—for supplying water direct to the condensers they draw from the bottom of the underground tank, but for pumping to the cooling apparatus they draw hot water from near the surface. The cooling apparatus is erected over a portion of the engine house roof—which is a concrete surface rendered in cement with a slight slope, and covers an area of about 900 square feet—see Fig. 17. The water is distributed in wooden troughs, and falls through numerous small holes on to sheets of thin galvanised corrugated iron fixed at an angle of 45 deg. on wooden trusses; it splashes down these slopes and is collected by another corrugated iron surface underneath, and carried into a trough delivering into the 6000-gallon tank supplying the condensers, which has an overflow discharging to the bottom of the underground tank. The total area of cooling surface is upwards of 2500 square feet. The arrangement of pumps and connections permits the water to be cooled on its way to the condensers, and when they require more water than the cooler can deal with, the reserve of 115,000 gallons underground can be drawn upon and cooled afterwards during the period of light load ready for the next evening's heavy load. A similar water cooling plant and storage tank have been in use at the Regent's Park Central Station with highly satisfactory results. The engines, dynamos, condensing plant, steam mains and water piping, were supplied by Messrs. Crompton and Co.

The main switchboard is designed to work on the five-wire system, with provision for coupling up to part of the three-wire system supplied previously from the Regent's Park station. Mr. Baynes, the newly appointed chief electrical engineer to the Vestry has, however, preferred to require the consumers to take their current from the King's-road station, at 220 volts instead of 110 volts, which has hitherto been the standard pressure, and he is, therefore, working the mains as a three-wire system at 440 volts, and leaving conductors Nos. 2 and 4 unused at present.

Each dynamo has a separate Aron meter, to register its output in ampère hours, fixed in the positive lead to the switchboard, and a single pole main switch is fixed in the same lead. The negative leads each have a duplicate fuse block and a magnetic cut-out to act when the current falls below twenty ampères, and also an ampère meter to show the load on the machine. Any dynamo may be placed on any circuit by inserting screw plugs in the coupling board as required. A resistance capable of absorbing about one-third of the full load of a dynamo is provided for testing purposes and for steadying the engines if necessary, when a new machine is to be switched into circuit. Five 440 volt "feeders" are connected to the board, and can be coupled by screw plugs to any one of three sets of omnibus bars, which may be worked at different pressures varying from 450 to 520 volts to suit the load. Each feeder has a volt meter and

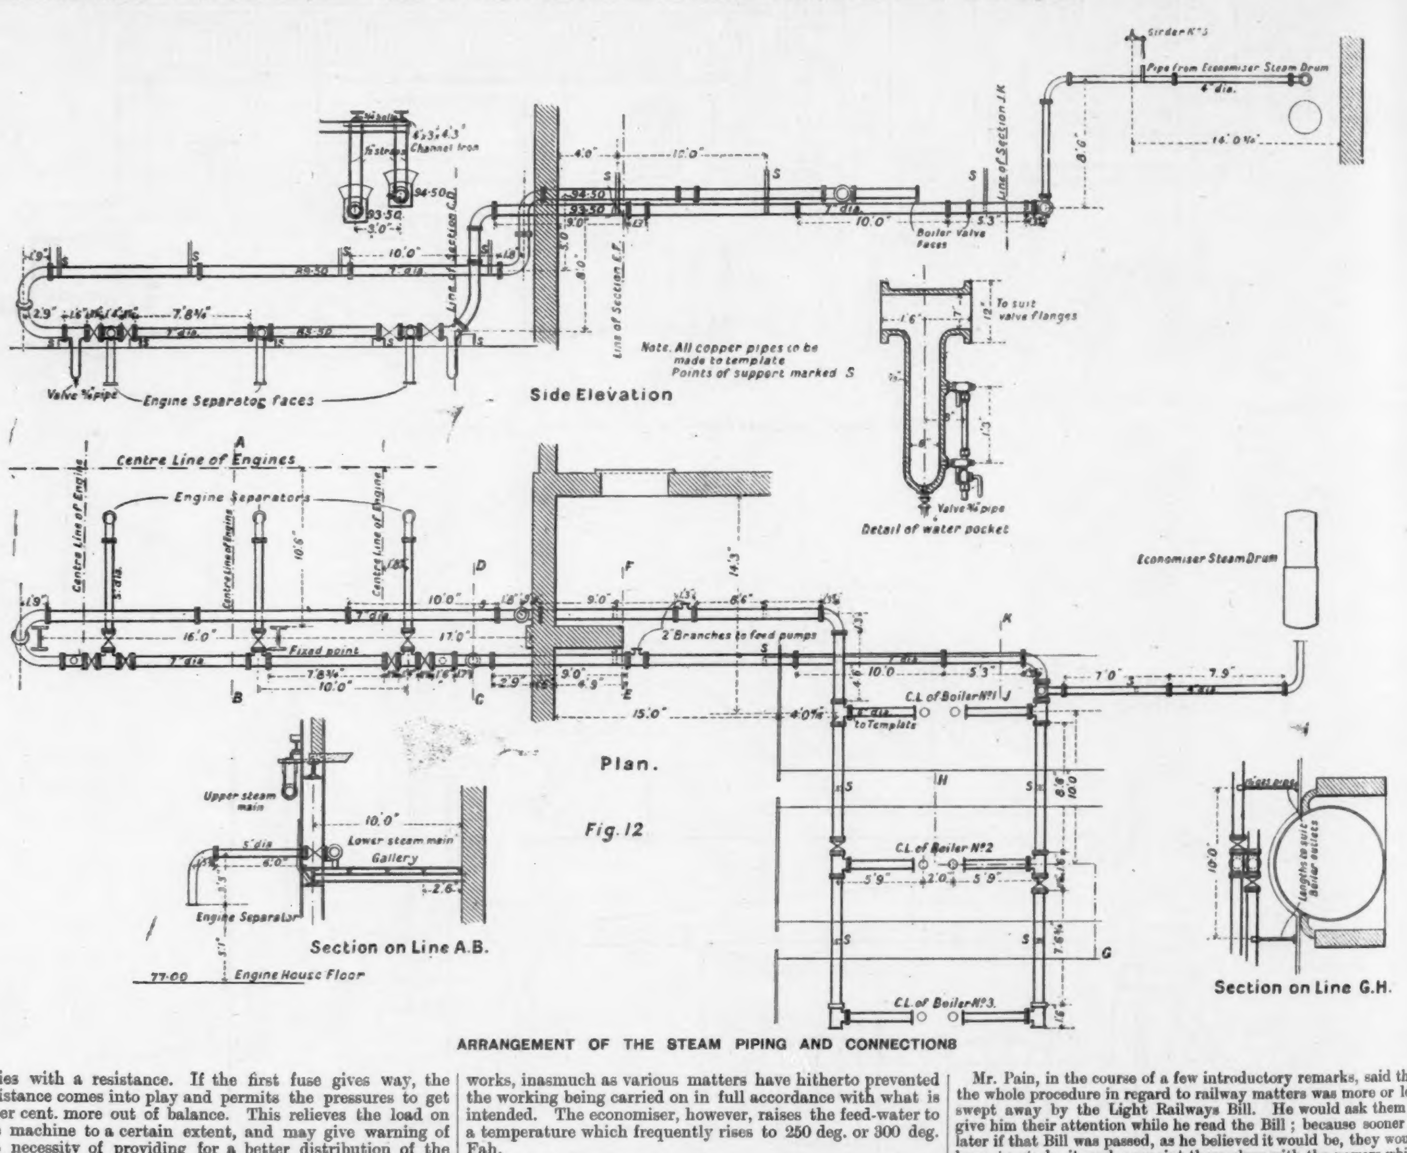
SECTION OF ENGINE HOUSE AND FOUNDATIONS

an ampère meter, the latter being provided with an additional scale showing the "volts required" on the feeder corresponding to the current passing, in order to give 450 volts at the further end of the feeder. The resistances of the feeders were carefully ascertained by passing large currents out through one lead and back through the other, and observing the drop of pressure and the current with the station potentiometer. The dynamo rheostats are fixed on a table immediately in front of the feeder instruments. Switches are provided for disconnecting the various bars while the screw plugs are being shifted, and resistances are used for regulating the pressures on different omnibus bars which are served from the same dynamos.

Additional regulation is provided by balancing motor transformers placed in sub-stations and at the central stations. These machines have four armatures in series wound on two drums on the same shaft. Each armature is designed for 50 ampères at 110 volts, running at 1200 revolutions per minute, and the magnetic fields are excited in series at 440 volts. An ampère meter is fixed in circuit with each armature, and fuses are provided in the leads connecting to the mains to protect the machines from overloading. The intermediate leads have two fuses each, one of which is in series with a resistance. If the first fuse gives way, the resistance comes into play and permits the pressures to get 5 per cent. more out of balance. This relieves the load on the machine to a certain extent, and may give warning of the necessity of providing for a better distribution of the lamps. If the relief is not sufficient, the second fuse will give way and cut out the overloaded conductor, leaving the machine running on the other circuits. Two of these balancing transformers are placed in a sub-station situated about 2400 yards south of the central station in Gray's-inn-road, and two in another sub-station under the Highgate-road railway station, about the same distance north of the central station.



ARRANGEMENT OF THE STEAM PIPING AND CONNECTIONS

The main switchboard and balancing transformers were supplied by the Electric Construction Company, who also wired the central station building for lighting by incandescent lamps and several Crompton-Pochin arc lamps. The mains which have been laid in connection with these works extend over upwards of seven miles of streets, and include over 40 miles of cables, varying in sectional area from one-tenth to one square inch of copper. The cables are made with untinned copper wire, insulated with specially prepared jute, covered with lead, then served with yarn, and protected by two armourings of steel tape braided and compounded over all.

The cables are laid direct in the soil, about 4in. apart. The straight joints are made with gun-metal sleeves screwed and sweated on to the copper strands, enclosed in cast iron split boxes, which are filled up with a bituminous insulating compound. Numerous fuse boxes are placed at intervals along the mains. The cables entering these are brought through sealed terminal boxes filled with insulating compound. A gun-metal terminal is sweated on to the end of the cable, and passes through an ebonite gland into the cast iron fuse box, which has a plate-glass air-tight cover. A loose tin plate is placed over the glass to keep it clean, and a surface cover of the usual kind is provided over the fuse box chamber, but not caulked down. The condition of the fuses can be seen at once without having to uncaulk or unscrew any cover.

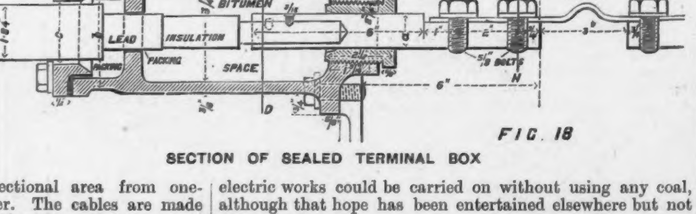


FIG. 18

SECTION OF SEALED TERMINAL BOX

Fig. 18 shows a section of a sealed terminal box. The fuses can be disconnected by box spanners inserted vertically from the surface. The insulation of the mains was tested in lengths of about 500 yards, and easily passed the specified requirements of from 1500 to 3000 megohms on such a length, according to the size of the cable, after two minutes' electrification by a 100-volt battery. On the completion of the work, the insulation of the entire system, including 41 miles of cable, with all the joints and fuse boxes, was found to be about 20 megohms. The whole of these mains were supplied by W. T. Henley's Telegraph Works Company. Fig. 15, page 285, shows a plan of the mains, the full lines being the old mains and the dotted lines those laid by Messrs. Henley.

It is too early as yet to give any reliable figures as to the result of the combination of the dust destructors and electric works, inasmuch as various matters have hitherto prevented the working being carried on in full accordance with what is intended. The economiser, however, raises the feed-water to a temperature which frequently rises to 250 deg. or 300 deg. Fah.

The standby boilers are also kept under steam without the use of any coal, while the destructors raise steam in a separate boiler which drives their forced draught fans and mechanical stokers. A great deal more will, of course, be effected when the arrangements for utilising the destructor gases are in full operation. It was never expected that the electric works could be carried on without using any coal, although that hope has been entertained elsewhere but not yet realised.

The electric works have been designed and carried out by Professor Henry Robinson, M. Inst. C.E., of 13, Victoria-street, Westminster, Mr. E. C. Thrupp being his chief assistant. Mr. J. F. C. Snell superintended the works in connection with main laying, electrical plant, &c., and he has been appointed resident engineer of the King's-road installation.

The destructor works have been designed and carried out by Mr. Wm. N. Blair, the Borough Engineer and Surveyor to the Vestry.

The electricity and public lighting department of the Vestry has been from the first under the control of a committee, of which Mr. Andrew Sweet has been the chairman throughout. Mr. Sydney Baynes is the chief electrical engineer to the Vestry, and Mr. A. E. Pycraft the chief clerk, Mr. C. Barrett being the Vestry clerk.

The total capital expended by the Vestry on electric lighting works now amounts to about £160,000, nearly all of which has been spent on work executed under the direction of Professor Robinson. The cost of the King's-road installation just completed will be about £44,000, exclusive of land. The destructor works and chimney shaft cost about £20,000.

LIGHT RAILWAYS.

At the ordinary general meeting of the Surveyors' Institution on Monday, Mr. Arthur C. Pain, C.E., read a paper on the Light Railways Bill. Mr. Daniel Watney, the President, took the chair, and amongst those present were, Sir George Leach, Mr. Alexander R. Stenning, Mr. J. W. Penfold, Mr. Harry G. Assiter, Mr. Martin Vigers, Mr. E. J. Castle, Q.C., Mr. Wheeler, Q.C., Mr. Edward Smyth, and representatives of some of the chief estates in the kingdom.

Mr. Pain, in the course of a few introductory remarks, said that the whole procedure in regard to railway matters was more or less swept away by the Light Railways Bill. He would ask them to give him their attention while he read the Bill; because sooner or later if that Bill was passed, as he believed it would be, they would have to study it and acquaint themselves with the powers which would be given them under what was an entirely new procedure in every respect.

Mr. Pain then read the text of the Bill, and added numerous criticisms upon clauses 1, 2, 3, 4, 5, 6, 7, 9, 11, 13, 15, 17, and 18.

"Clause 1: Assuming always that the Commissioners proposed to be appointed are persons skilled in the subject-matter to be inquired into, I think as an authorising body the Commission would be far superior to the County Council or Councils as proposed in the Bill of last year.

"I must, however express a doubt as to the desirability of paying only one member of the Commission, and I question whether two other gentlemen could be found with the necessary experience who would give as much time and trouble as might be necessary without remuneration. It must be remembered that an entirely new procedure is to be put in force, and it is of the utmost importance that the three Commissioners should be known to be skilled in legal, engineering, traffic, and financial questions. The same skilled professional assistance that has hitherto been engaged in railway undertakings will not be forthcoming in the projection of light railways, and it will be the duty of the new Commissioners to guide the promoters of light railway schemes in putting into shape what would probably be very crude projects. In nearly every case these light railways will join, either at one end or both, one or more of the main lines, and as the latter are managed by skilled boards of directors and officers with large funds at their disposal, considerable opposition may be expected if they think their interests are likely to be affected prejudicially. There is also sure to be some opposition from landowners, and the Commissioners will have to act the part of mediators between the conflicting interests of those who are in favour of a light railway and those who are not.

"It will be most difficult to get a rural district, and still more a County Council, to subscribe for the share capital of a light railway on the border, so to speak, of the district. Railways more often than not follow valleys, sometimes on one side of a river or stream and sometimes on the other. If, as most likely is the case, the stream forms the boundary between two rural districts, the light railway would be at the edge of each district, and the majority of the representatives of the rural council would never agree to tax themselves for the benefit of the minority. If the rural council or councils could make a special railway rate on those parishes in their district which were benefited by the railway, then, I think, in many cases a rate would be willingly agreed to and be much more popular than say a sewerage rate. I do not, however, see any provision in the Bill to meet this.

"Clause 5: This prevents the alteration of rating, which is usually made when cheap land is converted into a railway, and will work very well in helping to make lines where they will be of considerable local advantage in districts with little traffic at the moment, but which are capable of considerable development. Such places are often to be found, near the sea in particular. Sub-section (*c*) of this clause is the thin end of the wedge, and is a principle which might be extended with great advantage to all light railways. I think, however, a further useful proviso might be added, viz., that when 3 per cent. is paid for two years following on the ordinary stock, the railways should be rated in the usual way.

"Clause 9: Sub-section 3 of this clause, which provides for the rejection by the Board of Trade of a scheme for a light railway, will, I think, cause great hardships, which might in many cases be avoided if the Board of Trade, after a scheme has been put before them in general terms with the route of the line laid down on a 1in. ordnance map, would decide whether or no it is desirable that the project should go before Parliament or the Commissioners.

"Clause 11: (B) Here again the Commissioners will have most important questions of principle to decide, which must of necessity vary in every scheme inquired into, and my experience is that it is generally the public at large, and not the inspecting officers of the Board of Trade, who are so "exigeant" respecting questions of public safety. The Commissioners therefore will have to be strong men to resist the pressure of local authorities to expend unreasonable sums in costly road bridges, and of the public for expensive station buildings, signalling, &c.

"Sub-section (i.), dealing with railway rates, will also need very skilful handling by the Commissioners unless the light railways are to be worked at a loss.

"Clause 15: This provides for the expenses of local authorities in promoting schemes, and enables them to make a special rate on certain parishes. I think, as I said before, that this principle should be extended, and in all cases the parishes benefited rather than the county should be the rating unit. The question of repayment of loans dealt with under this clause is an important one. I think the repayment should not begin until five years after the opening of the line for traffic.

"Clause 17: This clause will enable many branch lines now working to get rid of most onerous conditions as to modes of working which have been forced upon them under their own Act, or under public Acts passed since they were constructed, and it will, I take it, enable the owners of many tramroads and mineral lines to get the necessary legal authority to carry passengers and goods as well as minerals, which will be of great advantage to the public.

"Clause 18: This gives power to get an amending order, which is a very useful provision, because it is generally found that as a scheme proceeds its usefulness is more appreciated, and more extended powers and a greater expenditure become necessary. In practice I think it would be found that the main line companies would be willing, under pressure of public opinion, if not of their own free will, to make grants in favour of light railways or give guarantees of minimum interest, or otherwise help in placing the necessary capital. They may also be willing to work the lines when constructed, but I cannot see any power in the Bill that would enable the main line companies to do one or more of these things simply by obtaining the sanction of their shareholders to such help being given under the terms and conditions embodied in the order. A clause to enable this to be done should be inserted in the Bill.

"I do not feel quite sure as to the powers of the Bill covering the case of an existing line being purchased by a county, district, or borough council by compulsion, and being extended or worked by the council."

Mr. A. E. Christy then read a short paper entitled, "Are Light Railways Desirable?" His arguments were, in a word, that light railways would cause a glut of produce at the great centres of population, and that the increased facilities of transport afforded to remoter districts would depreciate the value of those districts adjacent to the towns. The trains, running along the roadsides, would be dangerous to life and limb, and would injuriously affect the property near which they would pass. They would spoil the sporting and diminish the demand for horses. It was a paper which might have been listened to as usual in connection with railways sixty years ago.

Mr. J. W. Batten moved a vote of thanks to Mr. Pain, and said that pessimistic people were beginning to see that light railways would benefit the rural districts. Having spent about seven millions of other people's money in making railways, he had had opportunities of observing the effect of railways, and he had the assurance of landowners and their agents in the West of England that the rent had trebled and that the land had risen in value in the market, as the result of the rapidity with which produce—strawberries, for instance—could be put on the market. In Cornwall they might often see train after train with produce which could never have reached the London market but for the railway facilities. Wherever they got a railway they got this increase of value, which went into the pockets of the consumer. It might seem to some people a strange thing that they should have a meeting of that kind, so intelligent and so experienced, to consider the question of light railways and how to get them, when they had within 200 miles of that very door a series of railways which were second to none in the world, those in Holland, and when they had the Belgian and other systems, some of which they had probably visited. But in the matter of light railways they were in the position of lagging behind in this country, although they were the pioneers of railway enterprise. During the last few months he had travelled on these light railways—he would not call them "light," it was really a misnomer. There should be a classification, first, second, and third-class railways; and the test should be the speed and the weight upon the axle. Let the primary, the trunk, railways be inspected by the Board of Trade, *usque ad nauseam*, if they liked; let them make some relaxations when dealing with the secondary railways, those having a speed of not more than twenty miles an hour, and not more than ten tons on the axle. But let them do as they did on the Continent, if trains did not run at a higher speed than 12½ miles an hour and, had not more than eight tons on the axle, let the line be free of all control whatever. The reason why people in this country had not put their money into tertiary or light railways was the enormous expense of complying with the Board of Trade regulations as to signalling, bridges, and platforms. What are the faults of the Bill? It did not cut them entirely free from Board of Trade inspection. Then, again, there was no provision in the Bill enabling the existing railway companies to make or work the lines. It was idle for a body of promoters to plan a line if the main line with which it was to connect was apathetic or perhaps antagonistic. The Government should boldly say to the existing companies, "There are wanted in your vicinity a very large number of branch railways; if you will make those railways with your old main line rails and use your old rolling stock we will guarantee you two per cent." If the Government would guarantee a minimum two per cent. it would be worth while to make 400 or 500 miles of line each year, and with very moderate receipts the lines would prove profitable. Let them not think that 400 or 500 miles of line was a small amount to be made. During 1860-65 they were making between 500 and 600 miles a year, but in the last five or six years they were making less than 200 miles a year.

Mr. Christopher Oakley seconded the vote of thanks. He said he was not one of those who thought that the light railways would effect any very great improvement in the agricultural condition of the country, but they must not throw cold water on anything that was likely to alleviate the distress. As to some of the views expressed by the reader of the second paper, he hoped that it would not be thought that that Institution as a body held such views in regard to any public improvement. Landowners would meet such schemes in a liberal spirit.

Mr. W. W. Acworth, referring to the constitution of the Commission, said the Bill proposed to set up a court of two amateurs presided over by a gentleman who valued his professional prospects so highly that he was willing to take £1000 a year for five years, with the prospect of being cast aside at the end of the period. To do that would be merely to court failure. It was proposed to spend some millions of public money, and the only protection against the great railway companies making a hard bargain, which, in the interest of the shareholders, they must try to do, was that the Commissioners would know their business sufficiently to face the trained representatives of the great railway companies on terms of equality. The thing had been tried in Ireland with unsatisfactory results, and the same thing would happen in this country. That was the worst blot in the Bill, and he hoped it would be removed in the passage of the measure through Parliament.

Mr. P. W. Meik said that he agreed with much that had been said that evening, and he thought they must now take it for granted that light railways were desirable. He had had experience partly in the West, and also in Scotland and the North of England, and he could say that light railways were certainly desirable, and were so regarded by most landlords. Indeed, it was in consequence of that fact that he turned his attention to the matter at all. In railway matters they could not get very far without finding that a small line for two trains a day could not run without much the same regulations as the London, and North-Western Railway. That was the ruination of the smaller lines. The Board of Trade officials would not take the responsibility of allowing some of the things which they themselves considered to be reasonable. He would be glad if the Bill gave the officials more power to relax the rules. The clauses relating to capital were to his mind rather vague. It was a little difficult to understand how far Government intended to go. He gathered that the most that the Government intended to do was to subscribe the last quarter of the capital; that was to say, the promoters must first have three-fourths of it. As a rule, if they could get three-fourths there was not much difficulty about the remainder. The capital, too, was limited by the very objectionable clause requiring that the line should be worked by an existing railway company. It was, no doubt, very desirable that the lines should be worked by existing companies, but it would be highly objectionable to make that arrangement compulsory. It practically put the light railway into the hands of the adjoining railway company. Proper provision must be made to ensure the lines being kept open. Another important point was the possibility of a double inquiry in some cases. The Commission was a weak one, and the Government showed that it thought it was a weak Commission, because they could not trust it. If it was a strong body, the Government could confer upon it strong powers and finality. In several respects the method of procedure instituted by this Bill promised to be as costly as procedure by present methods.

Mr. Batten said that the clause empowering the adjoining company to work the lines was taken from the Irish Acts.

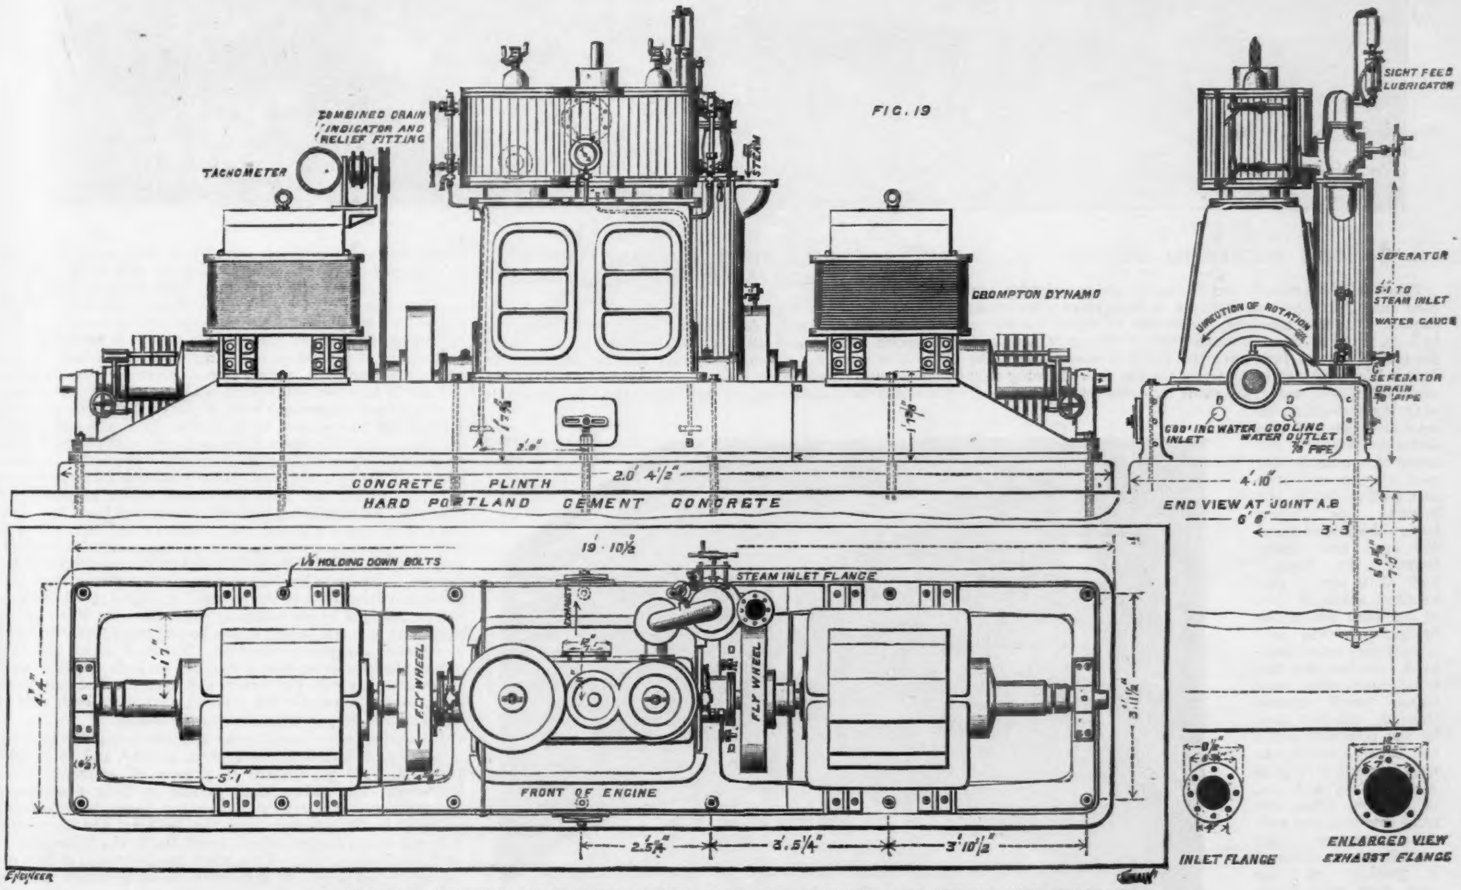
Mr. C. J. Owens said that to him, as a railway man, this was a matter of very great interest. He did not look upon light railways as the great panacea for agriculture, but he did think that they would assist the development of many quarrying districts and small seaside villages. Lines suitable for such work could be carried on with very small expense. He thought with regard to the Commission that to refer such questions to a body composed, as Mr. Acworth said, of two amateurs and a professional, would be a great mistake.

Mr. J. B. Walton said he thought that the Bill failed in two particulars. First, in regard to the Commission. He quite thought that if the Commission was to be of any practical value, the members must be men of practical experience. That was impossible for the amount put down in the Bill. The practical working of the Act would depend upon the Commissioners, and unless they thoroughly understood the work the Bill would be a failure. While the second point was, that it was doubtful which of the interested parties should take the initiative. Another blot in the Bill was, that there was no clause giving the existing railways power to subscribe to the capital of the light lines, to work them, or to give a rebate upon the traffic.

Sir George Leach said that an extensive experience with light railways in the north of Ireland, in India and elsewhere, including Bolivia, showed him that the narrow-gauge gave speedy and economical travelling. He thought, however, that the Bill should contain powers for the construction of ordinary tramways for use along the country roads.

Replying to the vote of thanks, Mr. Pain said it seemed to be the feeling of every speaker who had discussed the point that if the Government appointed really strong Commissioners, they would see a large extension of light railways all over the country. The difficulties and dangers apprehended by Mr. Christie would disappear as they did in the middle of the century.

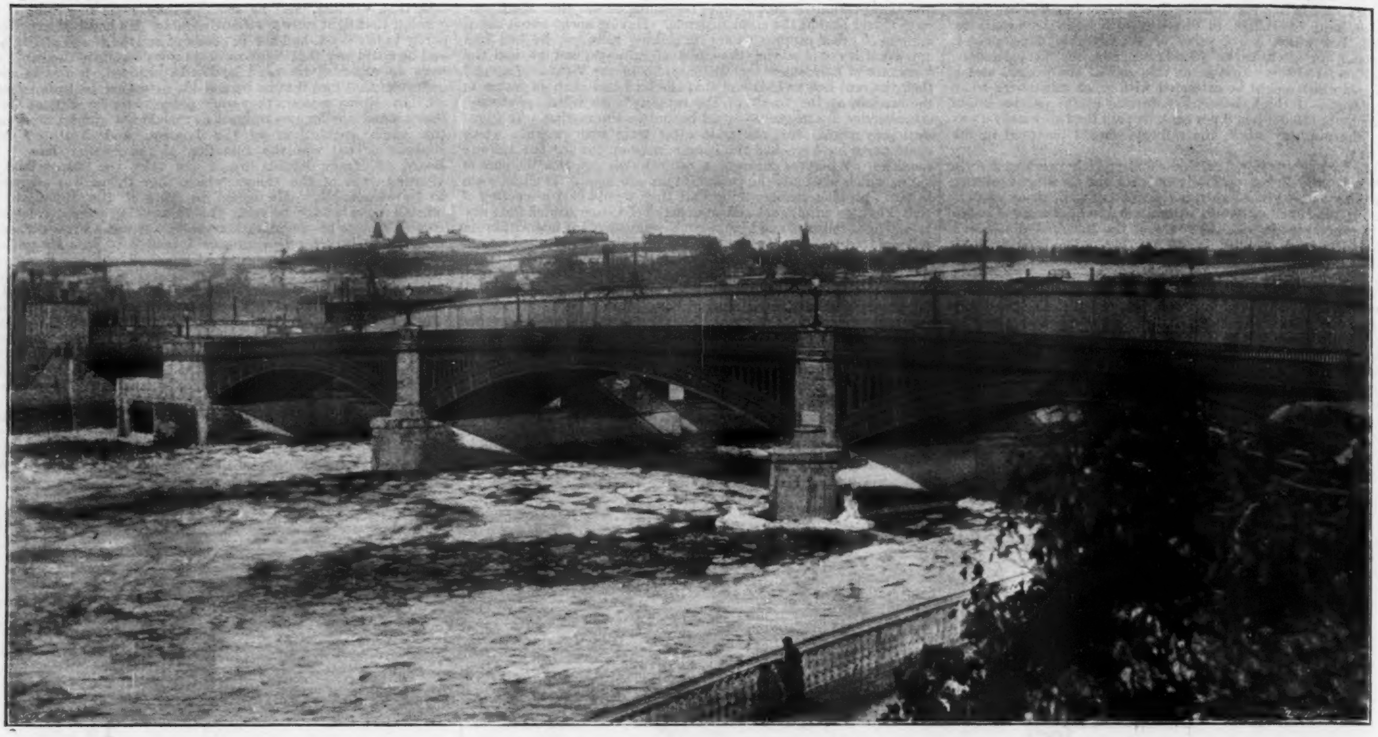
Mr. Christie having replied, the proceedings terminated.



ST. PANCRAS ELECTRIC LIGHT INSTALLATION—PLAN AND ELEVATION OF ENGINE AND DYNAMOS

THE CAST IRON BRIDGE OVER THE MEDWAY AT ROCHESTER, 1856.

SIR W. CUBITT, ENGINEER



THE ROCHESTER BRIDGE.

TWICE within a month the Rochester roadway bridge has been damaged by passing lighters or by lighters attempting to pass. The first accident, the results of which are shown in Figs. 2 and 3, occurred on the 20th of February last; and the second on the 14th inst. In the first case, as the light lighter Diamond was being towed up the river, drawing only about 3ft. 6in. of water, she came into contact with the arch near the springings, as seen, and, being of considerable weight, she removed a considerable part of the cast iron arch girders before she brought up. When loaded she carries about 350 tons, and trades between the Thames and Humber. She knocked about 25 tons of ironwork out of the bridge, but was not herself very much damaged. On Saturday last two lighters which were being towed abreast through another arch by the powerful steam tug Royalist, which, like the Diamond, belongs to Messrs. Cory and Co., of London, when she came into collision with the structure, and caused some damage, a portion of the cast iron work being broken. The vessels themselves were also injured; one had all her gear swept clean off the deck. Mariners complain that the design and construction of the bridge are such as to place very great difficulties in the way of modern craft passing through the arches. We illustrate the bridge by the above engraving. It crosses the river Medway near the railway bridge, and was designed by Sir William Cubitt, and constructed under him by Mr. John Wright, as resident engineer. It connects the towns of Strood and Rochester, and was completed in 1856. It has a clear width of about 40ft., and is entirely of cast iron on masonry piers, the swing bridge at the Strood end being of wrought iron girders. The bridge is of interest as being one of the earliest examples of the Hughes method of sinking foundation cylinders by means of compressed air. The total weight of ironwork is about 2500 tons. The view at the top of this page shows the character and position of the bridge, and the enlarged view of the broken girders gives a good idea of the damage done. For the tracings and photographs from which our engravings are prepared, we are indebted to the consulting engineer to the Rochester Bridge Wardens, Mr. V. de Michele, M. Inst. C.E.

View Showing Position of Fractures

EXPRESS PASSENGER LOCOMOTIVE, MANCHESTER, SHEFFIELD, AND LINCOLNSHIRE RAILWAY.

WE have much pleasure in illustrating this week the express passenger bogie locomotive engines designed by Mr. Harry Pollitt to work the express passenger service on the new London line which is at present in course of construction. There are six of these engines running on the London service between Manchester and Grantham, and there are thirty of the same type at present being built at Gorton. The chief feature of the engine is the "Belpaire" fire-box, which Mr. Pollitt has adopted as the standard pattern for all his locomotive boilers, and the centre of gravity of the engine being pitched up very high causes the engine to ride very smoothly.

The steam sanding arrangement is Messrs. Gresham and Craven's latest pattern. As well as under the driving wheels, Timmis's springs are fitted under the trailing wheels, and Messrs. Spencer Moulton's assistant springs fitted to both. As these engines are intended for long runs without intermediate stops, a tender has been designed to carry 4080 gallons. The webs of the crank axle are made egg-shape, with the greatest width opposite to the crank pin. The usual intermediate side buffers between engine and tender are not employed, and in their place is fitted one large central spring, resting in two castings, one on the engine and the other on the tender. This arrangement is found to effectually prevent any loose or jerky motion between the engine and tender. It reduces flange friction, and entirely obviates leaky feed-water connections. By the courtesy of Mr. Pollitt, we are enabled to add the specifications for the testing of materials which he has recently got out for these engines.

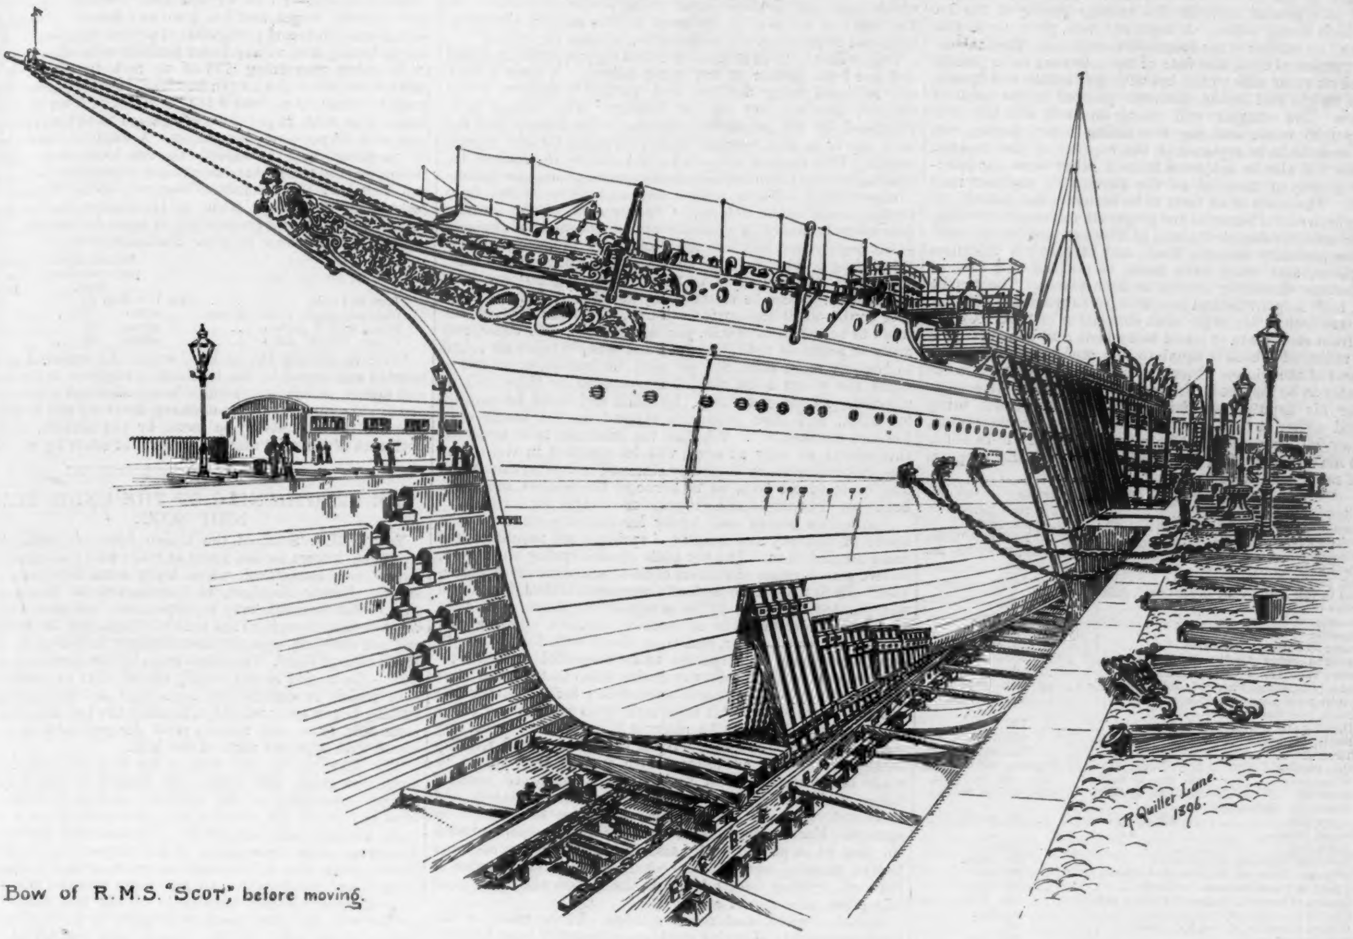
Locomotive crank axles.—The axles to be made of Siemens open-hearth steel, extra quality, and to be well annealed. An inspector will stamp the blocks in both webs before being broken out, which, after having been marked with the corresponding number of axle from which they are taken, must be subjected to the same annealing as and along with the crank. To remove the blocks, the webs must be sawn down as close as possible to a drilled hole through the web. Wedging will not be allowed. The crank pins to be rough turned—to dimensions given on tracing—before axle is annealed. All particulars of process of annealing to be furnished. Each axle must bear, both lengthwise and crosswise, a tensile strain of from 28 tons per square inch with 35 per cent. elongation, to 30 tons per square inch with 32 per cent. elongation, and a copy of the mechanical tests, signed by the makers, must accompany the test pieces from each axle, and clearly denote by number or marks the axles from which the tests have been made. A bar 1$\frac{3}{4}$in. square and 8in. long, with corners rounded to $\frac{1}{16}$in. radius, cut from the throw, either lengthwise or crosswise, to stand being doubled cold without fracture. Tensile and elongation tested with standard test bar, which is ·798 of an inch diameter, equal to ·5 of a square inch, and 2in. long. Tests to be witnessed by locomotive engineer or his deputy. Duplicate bending and tensile test pieces to be prepared and forwarded to the locomotive engineer. Each axle will be stamped by the company with the date when put to work, and any axle failing before having run 150,000 miles to be replaced at expense of makers. Name of maker and date of manufacture to be plainly stamped on both cranks of each axle whilst hot with $\frac{1}{2}$in. letters and figures. The cost of all tests to be borne by the makers, including both cost of material and preparations of same for testing.

Locomotive engine and tender straight axles.—To be made of Siemens open-hearth steel, extra quality, and to be well annealed. All particulars of process of annealing to be furnished. The makers shall provide at their own expense one additional axle in every twenty-five, or any lesser number ordered, to be selected from the bulk by the locomotive engineer or his deputy, which must stand the following test without fracture, viz.:—Five blows from a weight of 2000 lb., falling from a height of 25ft. upon the axle, which shall be placed upon bearings 3ft. 6in. apart, and turned after each blow. The test to be continued until the axle breaks. Then a tensile test piece to be taken, measuring ·798in. diameter and parallel for 2in.—the length in which the elongation is to be gauged—which must bear a strain of 32 tons per square inch with from 32 to 35 per cent. elongation, and a copy of the mechanical tests, signed by the makers, must accompany the test pieces, and clearly denote by number or marks the axles from which the test has been made. A piece, about 15in. long, showing fracture, to be slotted from the broken axle, and sent, together with a prepared duplicate test piece, carriage paid, to the locomotive engineer. Each test to be held to represent correctly the average quality of the material employed in manufacture. Each axle will be stamped by the company with the date when put to work, and any axle failing before having run 200,000 miles to be replaced at the expense of the makers. The makers' name and the date of manufacture to be well stamped in two places upon each axle whilst hot, with $\frac{1}{2}$in. letters and figures. The axles to be tested, as described, in the presence of the locomotive engineer or his deputy; and if the tests are not satisfactory, or should any defects develope during machining, power is reserved to reject any or the bulk of axles from which the tests have been made. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

Locomotive engine and tender tires of Siemens open-hearth steel, extra quality.—The makers shall provide, at their own expense, one additional tire in every fifty, or any lesser number ordered, to be selected from the bulk by the locomotive engineer or his deputy, which must stand the following test without fracture, viz.:—A weight of one ton falling upon it from a height of 15ft., 20ft., 25ft., and 30ft. successively, until a compression of 2in. per foot of inside diameter is reached; or, if desirable, the same result may be obtained by hydraulic pressure; the compression to be continued until the tire is doubled up or broken. Then a tensile test piece to be taken, measuring ·798in. diameter, and parallel for 2in.—the length in which the elongation is to be gauged—which

LENGTHENING THE CAPE MAIL STEAMSHIP SCOT

(For description see page 292)



SCOT
R. Quiller Lane.
1896.

Bow of R.M.S. "Scot," before moving.

View of "Scot" looking forward, after moving, showing gap of fiftyfour ft.

1896.

must bear a strain of from 48 tons per square inch, with 20 per cent. elongation, to 45 tons per square inch, with 23 per cent. elongation. If broken, a piece about 15in. long to be cut out of the tire showing the fracture, and sent, carriage paid, to the locomotive engineer. Each tire tested to be held to represent correctly the average quality of the lot from which it was taken. A duplicate test piece to be prepared and forwarded to the locomotive engineer. The makers' name, number of cast, and date of manufacture to be plainly stamped on outer edge whilst hot with ½in. letters and figures, and the weight and inside diameter painted on the inside of each tire. The company will stamp on each tire the date when put to work, and any tire failing before having run twelve months to be replaced at the expense of the makers. The tires will also be subjected to such other tests for hardness or quality of material as the locomotive engineer may require. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

Boiler and fire-box shell plates of Siemens open-hearth steel.—To be perfectly smooth, level, and of uniform thickness throughout, and must have name of makers and date of manufacture distinctly shown in four places. The tensile strain, both lengthwise and crosswise, to be from 27 to 32 tons per square inch, with 20 per cent. elongation in 10in. A piece taken from each plate to stand being bent cold to a curve, the inner radius of which is equal to one and a-half times the thickness of the plate. Prior to leaving the makers' works the plates to be inspected and tested by the locomotive engineer or his deputy, and failing satisfactory results being obtained either at that or any subsequent stage, machining, &c., they will be rejected. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

Dimensions of M. S. and L. Engine.

Cylinders, diameter	1ft. 6½in.
Piston stroke	2ft. 2in.
Steam ports	1½in. by 1ft. 4in.
Exhaust	3½in. by 1ft. 4in.
Lap of valves	1in.
Max. travel of valve	4 3/16in.
Lead in full gear, 1/32in.; in mid gear, 3/16in. bare	
Throw of excentrics	6¼in.
Diameter of sheaves	1ft. 5¾in.
Diameter of piston-rods	3⅝in.
Centre to centre of cylinders	2ft. ½in.
Centre to centre of valve spindles	6¾in.
Centre to centre of expansion links	5¼in.
Crank pins, connecting-rod, diameter	8½in. by 4¼in.
Coupling-rod pins, diameter	4in. by 4¼in.
Wheels, cast steel centres—	
Driving and trailing, diameter	7ft.
Bogie, diameter	3ft. 6in.
Tires	5½in. wide by 3in.

Axles, steel—	Bogie.	Driving and trailing.
Wheel seat	6½in. dia. by 6 11/16in.	8¾in. dia. by 7 3/16in.
Journals	5¾in. dia. by 9in.	8in. dia. by 9in.
Centre to centre of journals	3ft. 8½in.	3ft. 10½in.

Frames, steel—	
Thickness	1 1/16in.
Distance between, at cylinders	3ft. 11½in.
Distance between, over coupled wheels	4ft. 2in.
Front of frame to centre of bogie	5ft. 3¼in.
Centre of bogie to centre of driving axle	10ft. 3¼in.
Centre to centre of bogie wheels	5ft. 9in.
Centre to centre of coupled wheels	9ft.
Total wheel base	22ft. 2in.
Total wheel base, engine and tender	44ft. 8in.
Total length over buffers	53ft. 10¾in.
Boiler, steel—	
Mean diameter of barrel outside	4ft. 8in.
Length of barrel	11ft. ½in.
Height of centre line from rail	7ft. 11in.
Barrel plates ⅝in., smoke-box tube plate 1in. thick	
Fire-box shell, Belpaire form (steel), width at bottom outside	4ft. 1in.
Ditto, length at bottom outside	6ft. 4in.
Steam pressure, 170 lb. per square inch	
231 copper tubes, 1¾in. outside diameter, 11 and 13 B.W.G.	
Length between tube plates	11ft. 4½in.
Saddle plate ⅝in., back plate 9/16in., crown and side plate ½in.	
Fire-box, copper, length at bottom, inside	5ft. 8⅝in.
Fire-box, copper, width	3ft. 6in.
Fire-box, copper, mean depth	5ft. 5in.
Fire-box, copper, top of box to inside of shell	1ft. 5⅞in.
Tube plate 1in. thick, below tubes ⅞in.	
Back plate ⅝in. thick, crown and side ½in.	
Heating surface—	
Tubes	1209 sq. ft.
Fire-box	109 sq. ft.
Total	1318 sq. ft.
Grate area	20 sq. ft.
Ratio of grate area to heating surface	1 : 65·9
Smallest diameter of chimney	1ft. 2in.
Diameter of blast pipe nozzle	5 1/16in.
Tender—	
Diameter of wheels, cast steel centres	4ft. 3in.
Wheel base	13ft.
Capacity of tank	4080 gallons

Tender in working order	40	10
Total	87	8

Locomotive engine and tender frame plates.—To be of Siemens open-hearth steel, rolled in one plate, perfectly smooth and level, and must have the name of makers and date of manufacture distinctly shown in four places. The greatest care to be taken to ensure the frames being of uniform thickness throughout. The tensile strain, both lengthwise and crosswise, to be from 27 to 32 tons per square inch, with 20 per cent. elongation in 10in. A piece taken from each plate to stand being bent cold to a curve, the inner radius of which is equal to one and a-half times the thickness of the plate. Prior to leaving the makers' works the plates to be inspected and tested by the locomotive engineer or his deputy, and failing satisfactory results being obtained, either at that or any subsequent stage, machining, &c., they will be rejected. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

General plates.—To be of mild steel. To have a perfectly clean and smooth surface, and to bear a tensile strain of from 26 tons per square inch, with 20 per cent. elongation, to 30 tons per square inch, with 17 per cent. elongation in 10in. Prior to leaving the makers' works the plates to be inspected and tested by the locomotive engineer or his deputy, and failing satisfactory results being obtained, either at that or any subsequent stage, machining, &c., they will be rejected. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

Copper plates.—To be perfectly smooth and of uniform thickness throughout, except where required to be hammered to shape and thickness shown on tracing. To have name of makers and date of manufacture distinctly shown in four places. On each plate a test strip to be provided, which must bear being doubled cold without showing any sign of fracture, and the plates to stand flanging without showing any defects whatever. Prior to leaving the makers' works the plates to be inspected and tested by the locomotive engineer or his deputy, and power is reserved to reject any which may not be considered to be perfectly satisfactory. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

Copper bars.—To be of best soft rolled copper, perfectly round and free from surface or any other defects. A piece of each bar to stand being doubled cold until the surfaces touch without showing any sign of fracture. The testing to be witnessed by the locomotive engineer or his deputy, and the tests are to be sent, carriage paid, to him for further experiments. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

Copper tubes.—To be solid drawn and perfectly free from surface or any other defects. One per cent. of the number ordered to be tested in presence of the locomotive engineer or his deputy, and the ends must stand the following tests:—Expanding: the diameter to stand enlarging 20 per cent. Flanging: the diameter to stand enlarging 30 per cent. Flattening: pieces to stand being hammered flat and bent over double until the surfaces touch. Two per cent. of the tubes to be tested to 500 lb. per square inch with water, and must be perfectly tight. If upon analysis the tubes are found to contain more than one per cent. of impurities, or fail to stand the above tests, the lot represented by them will be rejected. In tapered tubes, the thick end must be parallel for 12in., and then gradually tapered on the inside only towards the thin end. Whether the tubes are to be annealed throughout, or only at ends, will be specified in the order. The maker's name to be clearly stamped in full on each tube. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

Locomotive engine and tender laminated springs.—To be made of the very best quality of spring steel, manufactured from Swedish iron. The top plate of each spring must bear, in two places, name of makers of steel and date of manufacture. Each plate to be perfectly tempered, nibbed, fitted, and well painted. Springs to be scragged six times, each time 1in. beyond loaded line of camber, without showing any permanent set whatever, and then tested with load to length given on tracing. The springs to be inspected by the locomotive engineer or his deputy during manufacture, and they must be tested under such supervision before leaving the maker's works; the whole to be strictly to tracing, and to his entire satisfaction, and he reserves the power to reject any which may not be considered equal to the stipulated requirements. If buckles are ordered with springs they are to be made of Lowmoor or best Yorkshire iron—stamped, soundly forged, with rounded corners to fit the springs accurately, and to be well secured. To be inspected before being fixed on springs. Each spring will be stamped by the company with the date when put to work; and if before the expiration of twelve months any failure occurs, the original camber is reduced, or other defects develope, the makers will be required to replace same free of cost.

Spiral, conical, and volute springs.—To be made of the very best quality of spring steel, manufactured from Swedish iron, and to bear the name of maker and date of manufacture. Section of steel to be as given on tracing, and ends to be ground off exactly square with centre line. To be perfectly tempered, painted, and tested by being compressed until solid—six times—without showing any permanent set whatever; and to be to length, with load, given on tracing. Prior to leaving the makers' works, the springs to be examined and tested by the locomotive engineer or his deputy.

Safety valve springs.—To be made of the very best quality of spring steel, manufactured from Swedish iron, and must have name of maker and date of manufacture distinctly shown. Section and ends of coils to be as shown on tracing. To be perfectly tempered, and tested by being extended six times with load, to length between hooks given on tracing, without showing any permanent set whatever. Prior to leaving the makers' works, the springs to be examined and tested by the locomotive engineer or his deputy, and to be painted. Power is reserved to reject any which may not prove to be satisfactory in all respects.

Cast steel wheels of Siemens open-hearth steel.—To be of good, tough, sound material, perfectly free from honeycomb, blow-holes, or any other defects; to be subject to annealing for at least fourteen days, and of the best possible workmanship throughout. The makers shall provide at their own expense one additional wheel in every twenty-five, or any lesser number ordered, to be selected from the bulk and tested by being raised in a running position and allowed to fall upon a solid foundation from heights commencing at 10ft., and continuing by advancing 5ft. each drop until the wheel is destroyed. Should any wheel break at either 10ft. or 15ft. drop, and develope fractures which give indications of unsuitable material or other defect, the lot from which the test wheel was taken will be rejected. From the broken wheel portions will be selected for forwarding, carriage paid, to the locomotive engineer for further experiments; and also a piece will be stamped from which a tensile test piece must be taken, measuring when finished ·798in. diameter, and parallel for 2in.—the length in which the elongation is to be gauged—which must bear a strain of from 28 tons per square inch, with 27 per cent., to 30 tons, with 24 per cent. elongation. On the rim or a spoke of each wheel a piece of suitable size to finish 1in. square must be cast, which, before being removed, must be stamped by the inspector, and then tested by being bent cold to a right angle round a bar 3in. diameter without showing any signs of fracture. No castings to leave the makers' works until inspected and passed; and although to all outward appearance they may appear satisfactory, should they on being machined prove to be defective, they will be rejected. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

Steel castings of Siemens open-hearth steel.—To be of good, tough, sound material, perfectly free from honeycomb, blow-holes, or any other defects; to be well annealed, and of the best possible workmanship throughout. All particulars of process of annealing to be furnished. The makers shall provide at their own expense one additional casting in every class, to be selected from the bulk by the locomotive engineer or his deputy, and tested to destruction in any way considered necessary—some of the broken portions will be selected to be sent, carriage paid, to him for further experiments. From the broken casting a test piece to be taken measuring ·798 of an inch diameter, and parallel for 2in.—the length in which the elongation is to be gauged—which must bear a tensile strain of from 30 tons per square inch with 17 per cent. elongation to 33 tons per square inch with 15 per cent. elongation. No castings to leave the makers' works until inspected and passed; and although to all outward appearance they may appear satisfactory, should they on being machined prove to be in any way defective they will be rejected. The costs of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

Steel forgings.—To be of the best Siemens open-hearth steel, soundly forged, and free from any defects. Forgings to be well annealed, and particulars of process furnished. From one in twenty-five, or any lesser number ordered, a test piece to be taken measuring ·798 of an inch in diameter, and parallel for 2in.—the length in which the elongation is to be gauged—which must bear a tensile strain of from 43 tons per square inch with 22 per cent. elongation to 45 tons per square inch with 20 per cent. elongation. A duplicate test piece to be prepared and forwarded to the locomotive engineer. Before leaving the makers' works the forgings to be inspected and tested by the locomotive engineer or his deputy. The costs of all tests to be borne by the makers, including both cost of materials and preparation of same for testing.

Tests for Lowmoor or other Yorkshire iron.—

		Tensile strain per square inch. Tons.	Elongation in 10in. Per cent.
Bars and rods	not less than	22	25
Channel, angle, T and H iron	ditto	22	23
Plates with the grain	ditto	22	16
Ditto across ditto	ditto	20	12

Prior to leaving the makers' works the material to be inspected and tested by the locomotive engineer or his deputy, and failing satisfactory results being obtained either at that or any subsequent stage, machining, &c., they will be rejected. The cost of all tests to be borne by the makers, including both cost of material and preparation of same for testing.

THE LENGTHENING OF THE UNION STEAMSHIP SCOT.

The R.M.S. Scot, of the Union Line of South African steamers, known in the trade as "the white albatross of the Cape," was considered, when built some five years ago by Messrs. Denny Brothers, of Dumbarton, to be a very long ship. However this may be, experience has proved that she was not long enough, as she is now in Belfast to be lengthened, and her carrying capacity considerably increased by Messrs. Harland and Wolff. They have engaged the Alexandra graving dock—the largest in the world, except that at Southampton—in which to execute the somewhat delicate operation of cutting her in two amidships, hauling the two halves asunder some 50ft. or so, and making good the gap between to correspond with adjacent parts of the hull.

The drawings in our issue of the 28th ult., together with those now given, will enable our readers to form a tolerably correct conception of the methods adopted by Messrs. Harland and Wolff for carrying to a successful issue a work of such delicacy and magnitude. To add still further to the somewhat brief description of the preparation for the work in our issue already referred to, we may say that after the huge vessel had been docked, the water pumped out, and due time allowed for any settlement on the keel blocks, which, by the way, had been specially prepared by having hard wood blocks, about 12in. by 12in., capped with iron plates, secured on top, work was commenced to prepare means for moving the forward half of hull. Launching ways were laid underneath, supported at short intervals on blocks of timber and wedges, extending from admidships to about 60ft. beyond her stem. After the ways had been thoroughly levelled and well greased, baulks of timber in pairs, 18in. square, were then laid as a base for the cradle which was to support and steady the hull during the operation of moving.

While this was in progress underneath, drillers were hard at work boring out all the rivets in the shell plating, frames, stringers, &c., in line with the midship water-tight bulkhead. The numerous stanchions carrying the promenade deck were also removed as far aft as the line of separation referred to, strong timber shores being securely fixed to the edge of this deck by angle bars and chains, the lower ends resting on wedges on the upper tier of small steps joining the dock altars. The lower edges of various houses on the spar deck below were then severed by all rivets, &c., being bored out, chains and screws for tightening being attached at the bottom to short lengths of angle iron bolted to the structure, the upper ends being securely bolted to the outer edge of the framing of the promenade deck, as shown in several of our views, opposite each shore or prop.

The cradle, the construction of which is very clearly shown on our drawings, was gradually erected under her, and was kept in place at the head by angle irons at top and sides, where it touched the hull, rivetted to the skin of the ship, and at the bottom by stretchers of timber, and chains made fast to eye bolts passing through the bottom binder. Strong chains were also slung from the top binder, passing under the keel as indicated, and every precaution taken to prevent the slightest lateral motion. To enable the hauling gear to be securely attached to the hull, a pair of heavy angle iron bars were bolted to her bottom near keel, almost amidship, to which massive chain cables were connected by shackles, and led forward immediately inside the launching ways, and provided at the outer end with heavy blocks, through which the hauling ropes were rove. Other straps of plate iron and double angles were bolted to her sides, four on each, to which chains and steel hawsers were attached further to assist in the hauling, and shown in our drawings.

As stated in our issue already referred to, a pair of powerful steam winches of the latest type were placed at each side of the dock gate or caisson closing the entrance, bolted to logs of timber 12in. by 12in., secured to the ground by angle bars, and rendered immovable by a few tons of pig iron before and behind, resting on the logs. The winches were supplied by steam through a 4in. galvanised wrought iron main from one of the Harbour Commissioners' boilers, in the pumping station shown in our general view. These were assisted by a couple of fully manned capstans at each side of the dock, abreast of the bow, seen in several of our views.

Everything was in place and ready for action on Saturday, the 7th inst., and on Monday morning, in the presence of a great number of spectators, shortly before ten, word was given to commence. In a very short time the immense fabric, set in motion by the hydraulic jacks placed inside amidships, commenced to move ahead, and the winches and capstans coming into play, kept her going, and in the short space of ten minutes the cradle supports came in contact with the stop blocks 54ft. ahead, thus bringing to a close an undertaking of no ordinary magnitude.

So carefully had everything been planned and carried out, that when tests were applied afterwards, it was found that there had not been the slightest deviation either horizontally or vertically in the part moved, as compared with the stern portion.

RAILWAY MATTERS.

What is probably the largest boiler of the locomotive type ever built was recently designed by Mr. F. W. Dean, mechanical engineer, of Boston. The boiler is 10ft. in diameter, has two corrugated furnaces, and has 5300 square feet of heating surface.

At a meeting last week of the committee entrusted with the scheme for promoting a tramway between Ashbourne and Derby, it was decided, in view of pending legislation with regard to light railways, not to proceed further this session with the Derby and Ashbourne Tramways Bill.

The Bois de la Cambre and Schaerbeck line of the Brussels tramways, about 5 kiloms., or three miles long, is to be worked electrically next year on the improved system of Ganz and Co., Budapest, with underground conductor, which will cost, for the two lines, about 30,000f. per kilometre, or £1931 per mile.

The new line from Connah's Quay to Bidston, which will greatly assist the mineral traffic between Wales and Birkenhead, has this week been opened for the conveyance of goods, and it is expected that by the 30th inst. it will be ready for passenger service. The journey from Liverpool and Birkenhead to North Wales will be much shortened.

Mr. Way, the chief engineer of the Assam-Burma Railway survey, has returned to Rangoon with his party. The survey shows that a line by the Hukong Valley would be cheaper and easier to construct than either the Aeng Pass or the Manipur scheme. A railway from Margherita, Assam, to Mogaung, a distance of 320 miles, would cost 400 lakhs of rupees, the only difficulty being the Patkai Range, which would have to be crossed at an elevation of 4000ft. The *Times* Rangoon correspondent says the Hukong Valley is described as a level country, well watered, but sparsely populated.

The State Railways of Massachusetts have now 1155 miles of track, and for the year ending September 30th, 1895, the total income was 13,246,371 dols., and the total expenditure was 12,595,212 dols. According to the report of the Railroad Commission of Massachusetts, the growth of business on these lines was almost phenomenal. There were carried the previous three years, in round numbers, 220,500,000 passengers; last year, 260,000,000, a larger increase than in any two preceding years combined. Of the 39,500,000 additional passengers carried, nearly 29,000,000 were carried on the railways of the eight largest established companies. Over 18,200,000 additional passengers were carried on the lines of the West End Railway, of Boston. This company carried the last year 155,231,506 passengers, or nearly 60 per cent. of the whole number carried on all the street railways of the State. The whole number of persons injured in connection with street railway operation was 1507, of whom 25 received fatal injuries.

At Rochester, U.S., there are about twenty miles of tramway track, and on this and some other lines Mr. J. Lyman made some experiments on the power required for electric traction. The Rochester track was in good condition at the time of the test. The number of cars on the road was forty, each weighing about eight tons and provided with a 15-horse power geared motor. In general the road was level, but in the heart of the town there were some gradients of from 3 to 4·7 per cent. Moving on the level, the necessary tractive power averaged 38 lb. per ton of car, and for the whole run over the four principal routes at 6·5 miles per hour, the average horse-power was 1·4 per car, and the maximum 6-horse power, this latter only being used momentarily. At Buffalo the same average power was required, but the maximum was 6·6-horse power. In a large Western city a car with the axles coupled direct to the motor, without the intervention of gearing, took 0·92-horse power per ton on the average, with a maximum of 4·7-horse power. In wet weather the tractive power required is reduced, the rain acting as a rail lubricant. Wetting of the rails round curves is particularly effective, the requisite traction power being thereby reduced by one-third. Comparative experiments made at Ithaca, N.Y., showed that on gradients the tractive force required exceeds that on the level by more than the theoretical amount.

What we believe to be the first application of polyphase currents directly to electric traction is, says the *Electrician*, now being made by Messrs. Brown, Boveri, and Co., at Lugano, in Switzerland. At this place an electric railway is being equipped with polyphase plant, and will, it is hoped, shortly be ready to start work. Preliminary trials have already been made with successful results. The power for this railway is derived from a waterfall, where a power-house has been installed with a 300-horse power turbine, driving two 150-horse power three-phase alternators. The power is generated at 5000 volts, and a portion of it is used by a chocolate factory near the power-house. The three-phase generators are of a special type, in which the only moving parts are the iron star-shaped pole cores. Both the field coils and the armatures are stationary. Three-phase current for the railway is conveyed at 5000 volts, overhead, over a distance of 12 kiloms—7½ miles—to Lugano, where it is transformed down to 400 volts by ordinary transformers. The power is there distributed to the cars by means of two aërial or trolley lines, the third conductor being supplied by the rails. Three-phase motors on the cars receive power through a double trolley-wheel apparatus; and a special form of controller is used when varying the speed or reversing the car. The motors are designed to give a normal speed of 15 kiloms—9⅜ miles—per hour. The advantages which attend the use of polyphase currents for electric traction are, principally, in enabling power to be derived from a distant source, and in allowing of the use of motors which require no commutator, collector, nor bare electrical conductor upon them. On the other hand, a double trolley line and the duplication of the trolley collector wheels are rendered necessary.

The French Society of Civil Engineers has been discussing a communication of Mr. H. de Grièges on "The Progress of Electric Traction on Railways." This related mainly to what had been done on the Chemin de fer de l'Ouest by the electric steam locomotive Fusée, and to proposals to construct a new one of much larger size. Mr. de Grièges, however, stated that besides hoping, in the course of the summer, to have two of the Heilmann locomotives at work, the company intended to start electric traction on a conductor system on a line between Saint Germain Ouest and Saint Germain Grande Ceinture. Mr. de Grièges stated that the relation between the work done on the pistons and the work returned at the draw-bar in his electric engine was 67 per cent. Mr. Key remarked that the best locomotives on the Nord Railway usually averaged about 55 per cent. Mr. de Grièges stated that the steam engine used was on the plan of the engines used in torpedo boats. Each of the six cranks was worked by a single piston-rod carrying two pistons instead of three. Mr. Bousquet said the efficiency of 67 per cent. corresponded to an efficiency of 90 per cent. for the steam engine, 90 per cent. for the dynamo, and 83 per cent. for the motors. This, however, was the efficiency at the wheel and not at the draw-bar. When allowance was made for the work done in moving the engine itself, the efficiency came down to 39 per cent. Mr. Réné Varennes said the electric locomotive contained a locomotive boiler, a steam engine with quite a number of cylinders, a dynamo, another steam engine with two cylinders used to excite the magnetic field, eight electric motors with their commutators and brushes, not to mention the bearings. It seemed to be a combination of complications, in which were united all the troubles of a fixed installation of electricity, an electric tramway, and an ordinary steam locomotive; and yet, Mr. Varennes complained, people had objected to the compound steam locomotive because it had four cylinders instead of two. After this, no one appears to have said any more.

NOTES AND MEMORANDA.

At a recent meeting of the Paris Academy of Sciences, a paper was read on "Observations on the Subject of Photography through Opaque Bodies," by M. A. d'Arsonval. In reviewing the work of M. G. Le Bon and his critics, it is shown that their results are not necessarily contradictory. The solar rays do not appear to penetrate a thin plate of metal, even of aluminium; if a plate of glass, however, especially a fluorescent glass, be placed above the metal screen, the photographic plate is affected.

None but domestic paving materials may be used in New York State if a Bill now before the Legislature succeeds in its passage. The Bill is practically aimed at foreign asphalt companies, as no other material would be affected. The foreign brands are the Trinidad, Venezuelan, and European rock asphalts, now controlled by about seven competing companies. The only American asphalts yet fully developed are those of Lower California and Utah. The foreign companies affected do not regard the Bill seriously, and look upon it as too unreasonable and unjust to pass. It is questionable whether such a statute would be sustained by the courts even if it were enacted.

A paper on the invisible radiations emitted by phosphorescent bodies, by M. Henri Becquerel, is published in a recent number of the *Comptes Rendus*. The light emitted by crystals of uranyl-potassium sulphate, $K(UO).SO_4 + H_2O$, can pass both through thin sheets of metal and also through black paper. This effect was first shown by covering a sensitive film with a metal screen, placing some crystals of the double sulphate on this, and then exposing to sunlight. But it was afterwards found that the crystals exerted the same photographic effect in the dark, a phenomenon which can hardly be attributed to phosphorescence, since $\frac{1}{150}$th of a second after exposure to light, these radiations are no longer visible.

The German manufacture of wire nails, the principal seats of which are in the Rhine Province and Westphalia, as well as at Osnabrück in Hanover, and Gleirvitz in Silesia, has so much increased during the last fifteen years that, after having met a gradually growing internal consumption, it has increased its exports by about 250 per cent. In 1880 the production was only 1645 tons; and in 1890 it had risen to 41,040 tons, while last year it attained 56,424 tons. The value of the exports during these fifteen years amounts to about 110,000,000 marks (£4,400,000). Nearly half the exports are taken by Great Britain for 14,300 tons, and Japan for 12,500 tons, while the Indian Empire absorbs 3730 tons, and Australia 2770 tons.

The recent discovery of argon in atmospheric air, by Lord Rayleigh and Prof. Ramsay, aroused such great interest, that it has been resolved, on the repeated request of the "general public," to prepare a volume containing an account of the methods of extracting the new gas from air, and of its properties, explaining, where necessary, in popular language, the basis of the reasoning employed in drawing conclusions relative to argon. The little work, which has been written by Prof. Ramsay, and will be published by Messrs. Macmillan and Co., treats of all the progress made in this fascinating branch of chemistry by a number of men, almost all of them English. *Nature* says the volume will contain portraits of Cavendish, Boyle, Lavoisier, and other early discoverers.

Considering the importance to the living of the discontinuance of the extension of graveyards and cemeteries, it is satisfactory to find that cremation as a means of disposal of the dead is steadily gaining favour. From the report of the Council of the Cremation Society for 1895, we see that 150 cremations were carried out at Woking during the year, and 58 at Manchester. When the society commenced operations in 1885, only three bodies were cremated, but this number has continuously increased since that year. At the present time, the crematorium at Manchester is the only one in operation in England besides the one at Woking. Another is, however, *Nature* says, being erected near Liverpool, and will shortly be opened for use; and last November a building, comprising a crematorium, chapel, and waiting-rooms, situated on the outskirts of Glasgow, was opened by Sir Charles Cameron.

The old view of igneous rocks as merely accidental and irregular intruders into the regular sedimentary series has been greatly modified by the results of petrological researches, and now it has been found possible, from an investigation of rock structures, to obtain a complete account of a series of events in a district by Messrs. Holland and Saise in the Giridih coalfield in Bengal. They show how a liquid rock-magma of highly basic composition was injected as a series of dykes through the rocks of this area at a temperature so high that near the dykes the coal was coked and columnar structure developed in it, while sandstones were so far fused that they came to closely resemble siliceous lavas. This magma was rich in chlorine, as the abundance of apatite in it shows, and from it thermal waters conveyed chlorides in solution to permeate the rocks around. This permeation by chlorides produced marked changes in certain more ancient igneous rocks, so that when at a later stage earth-movements crushing them led to their metamorphism and re-crystallisation, the results of that metamorphism were quite different in the areas where the chloride-permeation had and had not been effected. Where there were no dykes to supply the chlorides, hornblende-schists were produced; in the neighbourhood of the dykes, scapolite rocks were formed. These and other interesting facts, *Nature* says, are worked out in convincing manner in a paper contributed to the *Records* of the Indian Geological Survey.

At the last meeting of the Meteorological Society, Mr. Frederick Gaster, F.R. Met. Soc., of the Meteorological-office, delivered a lecture on "Weather Forecasts and Storm Warnings: How they are Prepared and Made Known," which was illustrated by numerous instruments, diagrams, and lantern slides. Mr. Gaster said that in the preparation of forecasts the position held by the barometer was so much more important than that of any other instrument, that its action must be fully comprehended if the rest of the work was to be at all clearly understood. He then referred to the use of a single isolated instrument, and showed how new light was thrown on the observer who could have telegraphed to him simultaneous observations from a large number of places scattered over a considerable area of the earth's surface. The kind of variation in the distribution was dealt with, isobars were drawn, and the phenomena which they exhibit in the way of high and low-pressure areas described. Mr. Gaster drew attention to the obvious importance of the variation in the weather over a given area caused by alterations in the position of the cyclonic and anti-cyclonic systems, and the importance of the fact that the former tended to move round the latter from left to right. This led to some remarks on the indications observed when disturbances were advancing towards our islands from different points. Attention was drawn to secondary systems, both of high and low-pressure, the forms they assume, and their effect on the weather which, but for their presence, would probably have accompanied their primaries, and the necessity for allowing for such systems in sending warnings to our coasts. The lecturer then remarked on the value of auxiliary information, such as is to be obtained from decided changes in the direction of the wind, sudden changes of temperature, the movements of clouds at different levels, observations made at high-level stations, and telegrams from the United States. Mr. Gaster next explained how the information is made known to the public. Forecasts are issued by the Meteorological-office in the daily weather report, and also communicated to the Press. Hay harvest forecasts are issued to certain selected authorities, who circulate them as much as possible in their neighbourhood. Storm warnings are telegraphed to our coasts, with instructions to hoist the cone point-up or point-down.

MISCELLANEA.

Messrs. Earle's Shipbuilding and Engineering Company, of Hull, have received an order from the Admiralty to construct two 20-knot cruisers of the Pelorus class. The machinery for these vessels will also be constructed by Messrs. Earle's Company.

In order to satisfy public opinion, the French "coast-defence" armour-clad Bouvines has undergone a further four hours' trial at Brest with full satisfaction. The *Army and Navy Gazette* says that a mean speed of 15·3 knots was attained with natural draught.

The cry of the French press with regard to the recent naval constructions is just now particularly vehement—*e.g.*, from *Le Moniteur de la Flotte*, "*A bas les superstructures!*" Of course, we quite agree. They have cost a lot of money to put up; they will now cost a lot of money to take down. Pity the French taxpayer!

At a meeting of gentlemen connected with the engineering and shipping industries of the Cardiff district, presided over by Mr. John Lowdon, J.P., of Barry, it was unanimously decided that a hearty invitation should be sent to the members of the North-East Coast Institution of Engineers and Shipbuilders, asking them to visit Cardiff and the Bristol Channel ports during the ensuing summer.

A Belvedere Tower, nearly 200ft. in height, similar to those erected at the World's Fair, Chicago, and at the Paris and Philadelphia Exhibitions, will be erected this season at the Empire of India and Ceylon Exhibition. The tower will be provided with two passenger lifts, and have several balconied storeys. The top platform will accommodate about 100 persons. The tower will, at night, be illuminated by a lighthouse lamp of 4,000,000-candle power.

For some time past the Rotherham Corporation have had under consideration a scheme for dealing with the sewage of the borough. At their last meeting the Town Council unanimously decided to retain Mr. R. E. W. Berrington, Assoc. M. Inst. C.E., Wolverhampton, as engineer to carry out the scheme in accordance with his plans and estimates. The chairman of the committee said that including land the total expenditure would approach £100,000.

The British second-class cruiser Dido, of 5600 tons, whilst being launched on the 17th inst. from the yard of the London and Glasgow Engineering Company, Govan, Glasgow, stuck at the foot of the ways and lies in a very dangerous position, about three-fourths of her being in the water and the remainder on land. The ways close to the water were apparently laid in the mud, which sank with the weight of the vessel. Attempts were made to get her off with tugs, but without success. She was, however, moved 17ft. on Wednesday, and by the aid of two powerful pontoons it was thought she would be got off yesterday.

In an interesting review of American milling in the past year, the *Milling World* says:—"There were 1387 mills built in the United States in 1895. Of these 1139 are mills to grind wheat, and the rest are corn, feed, meal, oatmeal, pearl-barley, rye, hominy, grits, and other cereal plants. The burned mills number 382, which, subtracted from the 1139 new mills, leave 857 mills as the net gain of the year. In 1894 the net addition was 670 mills. Taking into the account the enlargement of 585 existing mills in 1894, it appears that, in spite of all the adverse conditions, the past year was better than 1894, far better than 1893, and quite equal in the way of profits and development to 1892 and 1891."

With the increasing facilities for obtaining the electric current, many new applications of it have been brought forward, and among them the optical or magic-lantern form of light requires the presence of oxygen and hydrogen gases under pressure, and although of late years the apparatus employed has been greatly simplified, it is still cumbrous, and possesses drawbacks which make it compare very unfavourably with the two simple wires. A new form of lamp or regulator to furnish an electric arc light for this purpose has been invented by Mr. C. M. Hepworth, and introduced under the name of the Ross-Hepworth projection lamp by Messrs. Ross, opticians, London.

At a meeting of the Farnham Mechanics' Institution, on Tuesday, in the Assembly Rooms, Mr. J. H. Knight, J.P., gave a lecture on "Motorcycles." Mr. Knight traced the history of motorcycles, and referred to the steam carriage he invented some years ago. A series of views was shown by means of an oxy-hydrogen lantern, kindly lent by the president, and it was mentioned that in Paris motorcycles are allowed to travel at the rate of eight miles an hour. He said that probably the cost of a small car to seat two people would be £75 or £80, and it would travel eight or ten miles an hour. Mr. Knight's petroleum motorcycle, which is believed to be the first manufactured in this country to carry two people, was exhibited in motion.

On Tuesday, Messrs. J. and H. Gwynne showed in operation one of their suction dredgers at work on the bed of the Thames at Hammersmith. The dredger is fitted with a complete set of plant, including boiler, and direct driven centrifugal pumps, and tackle for operating the dredging nozzle and delivery pipes. The dredging nozzle is of novel design, and is fitted with a number of moving louvres, so that the current of disturbing water varies as to its incidence, and increases the rate of stirring and removal of the spoil under the action of the current to the pump. The operation of the dredger was witnessed by a number of engineers, who saw it fill the central part of a ballast barge, and was much pleased with the action of all the pumping plant.

The Admiralty have sanctioned the following improved scale of salaries per annum to the engineering and constructive staff at the London establishment and at the dockyards, and these increased rates of salary will come into force on April 1st. At the Admiralty.—Director of Naval Construction's Staff: The Senior Chief Constructor, £1000 to £1150; two Chief Constructors, £850 to £1000. Director of Dockyards' Staff: Chief Constructor, £1000 to £1150; Engineer Assistant, £800 to £950. Engineer-in-Chief's Staff:—Chief Engineer and Inspector of Machinery, £1000 to £1150; Engineer Inspector for Gun Mountings, £620 to £770. At the Dockyards.—The Chief Constructors at Portsmouth, Chatham, and Devonport, £700 to £850; at Sheerness and Pembroke, £600 to £750; at Malta, £650 to £800; at Hong Kong, £600 to £750. The Chief Engineers at Portsmouth, Chatham, and Devonport, £600 to £750; at Malta, £550 to £700; at Hong Kong, £500 to £650. These officers also have Government residences.

The new United States Navy, since March 3rd, 1883, has cost 110,371,710 dols., according to the late speech of Senator Proctor, of Vermont; he included in this statement all ships authorised or in course of construction. In the same time they have expended only 10,631,000 dols. on coast defences, and many millions in deepening the approaches to their harbours, and making them more accessible to an enemy's fleets. For the sum named the United States will have 8 battleships, 4 double-turreted monitors, 1 barbette coast-defence turret vessel, 1 harbour defence ram, 2 armoured cruisers, 7 protected cruisers, 6 partially protected cruisers, 20 cruisers, 17 gunboats, 1 dynamite gun vessel, 9 torpedo boats, 1 dispatch boat, and 1 naval cadet practice vessel. These ships will carry 82 8in. guns, 18 10in. guns, 12 12in. guns, 24 13in. guns, 3 dynamite guns, and 187 5in. and 6in. rapid-fire guns. Senator Proctor argued that land defences were more efficient than a navy for the protection of our coast line, and said that our navy having been well advanced, we should now turn our attention to the shore defences, as the best means of maintaining peace.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

J. T. (Dalkeith.)—*To what School of Engineering do you refer?*

C. E. W. (Parel.)—*The British Motor Carriage Syndicate, 95, Billiter-buildings; 49, Leadenhall-street, London.*

R. W. H.—*We cannot recommend any makers, but you will find them in Kelly's Directory of the Engineers' Iron and Metal Trades and in the large London Postal Directory.*

D. H. W. (Denbigh.)—*We cannot give any publication to the matter you send, and cannot assist in proposals of the kind. It is a matter for advertisement.*

LOCOMOTIVE APPRENTICE.—*As almost every possible arrangement of cylinders and method of working locomotives compound has been proposed or patented or used, it is impossible to say whether your suggestion has been tried or not. We fancy it has.*

A. B.—*The following canals have been converted into railways:—Andover Canal, 22 m. 6 f.; Croydon, 9 m. 4 f.; Glastonbury, 14 m. 2 f.; Hereford and Gloucester, 34 m.; Leominster, 22 m.; Monmouthshire, part, 6 f.; Oakham, 15 m.; Somersetshire, part, 7 m. 2 f.*

F. O.—*It is a matter of indifference whether you pass the water or the steam through the tubes. It is only necessary in either case to take care that there is efficient circulation through every portion of the condensers. The water will take the line of least resistance in all cases.*

DUPLEX TRICYCLES.—*There is no maker now, as far as we know, of the duplex tricycle in this country. About a dozen years ago it was invented and patented in England by Mr. C. T. Crowden, and a four-wheeled machine for two riders side by side was patented by the same inventor, consisting of two coupled bicycles, with a connecting axle of differential gear between. Another machine, with two steering wheels in front, for two riders over one rear-driving wheel, was made by him, but the tandem machines seem to be generally preferred. The single track bicycle for two riders side by side has also been made in this country.*

CONDENSING WITH TIDAL WATER.

(*To the Editor of The Engineer.*)

SIR,—I should feel obliged if any of your readers would give me information as to the best means for condensing from 600 H.P. compound engines working on the side of a tidal river such as the Tees, Tyne, or Usk, assuming a tidal rise of 40ft. It is noticed at low tide that the water is very muddy. The water used for the boilers generating steam would be the towns supply, and, if possible, should be returned after condensation to boilers again.

Any information would be greatly esteemed. Thanking you in anticipation of insertion.

TIDAL.

Wolverhampton, March 14th.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. £0 14s. 6d.
Yearly (including two double numbers) .. .. £1 9s. 0d.

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. £0 18s. 0d.
Yearly .. .. £1 16s. 0d.
THICK PAPER COPIES—
Half-yearly .. .. £1 0s. 3d.
Yearly .. .. £2 0s. 6d.

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

INSTITUTION OF JUNIOR ENGINEERS.—Saturday, March 28th, at 7.30—11.30 p.m. Conversazione at the Westminster Palace Hotel, Victoria-street, London.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, March 26th, at 8 p.m. Paper: "Telephone Exchanges and their Working," by Dane Sinclair, Member.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, March 24th, at 8 p.m. Paper: "The Thermal Efficiency of Steam Engines," by Captain H. Riall Sankey, late R.E., M. Inst. C.E. Friday, March 27th, at 8 p.m. Paper: "Closing a Dock-Entrance for Repairs," by Mr. Julian S. Wise, Stud. Inst. C.E. Mr. A. C. Hurtzig, M. Inst. C.E., will preside.

NAVAL ARCHITECTS.—See page 297.

SOCIETY OF ARTS.—Tuesday, March 24th, at 8 p.m. Foreign and Colonial Section. Paper: "The Colonies and the Supply of Dairy Produce and Products of Petite Culture," by Charles R. Valentine. Sir Westby B. Perceval, K.C.M.G., will preside. Wednesday, March 25th, at 8 p.m. Paper: "Our Food Supply, as affected by the Farming of the Future," by Professor James Long. Thursday, March 26th, at 8.30 p.m. at the Imperial Institute, South Kensington. Indian Section. Paper: "Kashmir: Its People and its Products," by Walter R. Lawrence, I.C.S., C.I.E. The Earl of Dunmore will preside.

THE ENGINEER.

MARCH 20, 1896.

A WATER BOARD FOR THE METROPOLITAN COUNTIES.

THE London water question is now entering on a new and remarkable phase. On Monday evening the expected Government Bill relative to this long-contested subject was presented to the House of Lords by Lord James of Hereford, and was read a first time after a brief but interesting debate. By this measure it is proposed that a Board shall be established for the purpose of dealing with the supply of water to London and the surrounding districts. It will be seen that the Government have felicitously escaped any direct dealing with the water supply, and have simply devised a plan by which a new authority will be entrusted with the task. In order that the authority thus created shall not indulge in any vagaries on the subject, the new body is simply armed in the first instance with such powers as are already exercised by the London County Council under the Metropolis Water Act of 1871. In the next place, the Board will be in a position to negotiate with the Metropolitan Water Companies, and to adopt provisional agreements respecting any matters relating to the water supply of the districts now occupied by these companies. But for the purpose of giving effect to such agreements, the Board must seek the sanction of Parliament by means of Private Bills. The Board will also have power to oppose Bills brought in by other parties relative to the supply of water to London or its environs. In this aspect the scheme looks rather weak and unnecessary; but from another point of view it has a more potent and dignified appearance. The Board is to operate not merely over the 121 square miles of inner London, but over the entire area of 620 miles constituted by the Parliamentary districts of the London Water Companies. Into the outer portion London itself is overflowing, and the Government have wisely discarded the idea entertained by the County Council, that the metropolis as at present defined by the Registration Act is to have a water supply of its own. leaving the several authorities of the 500 square miles beyond to look out for themselves. That the outer areas should be represented on the Board is perfectly reasonable, and the Bill provides an all-round system for the purpose. The London County Council will have power to appoint sixteen members. The Corporation of the City will have two. This is an awkward feature, for West Ham is to have a like number. A mere county borough—populous it is true—is raised to the same position as the ancient City, with its enormous rateable value and fabulous wealth, though having a small appearance in the census of the sleepers. The total number of members on the Board is made up to thirty, by giving two representatives each to the County Councils of Middlesex and Essex, and one each to the Councils of Surrey, Kent, Hertfordshire, and Croydon, together with one to the Conservators of the Thames, and the like to the Lea Conservators.

The Government have acted with diplomatic skill. Undertaking to deal with the water question they have avoided all risk to themselves by simply creating a Water Board to do the work. The Board may propose what it pleases, and Parliament can say aye or nay as it chooses. Neither the initiative nor the result will affect the Government. The only difficulty is in getting the Board into existence. The County Council are not likely to be satisfied with sixteen members out of thirty. Their desire is to possess the water supply for themselves, or in a slender alliance with the Corporation. But the dream may as well be dismissed. The water question has outgrown the County Council, just as London has outgrown its ancient limits, except that the process has been especially rapid in the former case. The project for bringing a supply of water from Wales is of a magnitude which would seem to agree with supplying both London and all the outer districts. Yet the most we can hear of in that direction is a supply of water in bulk. The Welsh project is weakened in the hands of the Council by the attempt to claim "London for London," leaving the outer areas to arrange as they best may. The Royal Commissioners of recent date, when inditing their report, took in all "Water London," and reckoned that in forty years' time the population of the 620 square miles would exceed 11,000,000. Herein lies the gravity of the water question, and it is this which naturally suggests the creation of a municipal authority representative of the entire area to be provided for. If there is to be a colossal scheme for bringing a supply of water from the mountains of Wales, such a project would seem to fall naturally into the hands of a Water Board charged with providing a supply for the widespread area of London and the surrounding districts. So huge an undertaking overtops a County Council designed for London alone, and itself desirous, in respect to the water supply, of possessing nothing more than the crowded and profitable area of the inner circle. The Council has professed that the outer districts did not wish for its interference, and preferred taking care of themselves. This is very likely, seeing that the outer districts send no members to Spring Gardens. But the feeling may be different when representatives from these districts take part in the deliberations of a Metropolitan Counties Water Board.

That the Government Bill will be severely criticised is inevitable. It is felt in some quarters that the City is not fairly dealt with, and that the representation granted to the London County Council is larger than it ought to be. Those who adhere to the Council object to the creation of any new authority to deal with the Metropolitan water question, considering the Council quite sufficient for the purpose. It is said that the Progressives are determined on doing their utmost to wreck the Bill. Should they succeed, the effect can scarcely be anything else than that of leaving the companies masters of the situation, though they appear to make no objection to the Bill as it stands. The companies would rather be let alone, but the prospect of escaping from the clutches of the County Council is tempting, though another power is to be brought upon the scene. To the Progressives on the Council the Bill is nothing other than gall and wormwood. It threatens, as the ex-deputy chairman declares, to diminish the attractiveness of the work carried on by the Council, so that men of ability will gradually cease to offer themselves for its service. A morning paper which speaks for the Council remarks that "the hybrid board which is to be the water authority of the future" is to absorb "at one swoop" every power the London County Council has hitherto possessed in relation to the water companies or the supply of water, except "such small matters" as the water rights of the Fire Brigade. There will still be water to put out fires, but the County Council will be left shorn of its splendour as the public authority destined to command the water supply of the greatest city in the world.

The report of the Water Committee of the London County Council advocating the Welsh scheme of supply, and recommending that a Bill should be brought into Parliament next year for carrying out a section of the undertaking, has awaited the decision of the Council for some weeks past, but is now once more adjourned, standing over until after Easter, "in view of the proposals of the Government." Six of the famous Transfer Bills, which have not yet passed the second reading, were to have reached that stage on Friday last, but the approach of the Government measure has kept them back until Tuesday next, when it will be seen what fate awaits them. But if the Water Board Bill is to meet with success, it matters little to the Council what becomes of the Transfer Bills. Sir Arthur Arnold has been negotiating with some of the companies for the purchase of their undertakings, and reports that he has "met with no material discouragement." But even should he succeed, it may prove that he has only prepared the way for the Water Board, which will be in a position to complete the purchase Sir Arthur has previously negotiated. Had the County Council been reasonable in days gone by, instead of attempting to seize the companies by the throat and dictating the most outrageous terms, the present situation might have been a different one. The Council has sown the wind, and it now has to reap the whirlwind. Of the three Bills promoted by the water companies it is to be remarked that they also await their second reading on Tuesday, but the Government appear willing that they should pass this stage and be referred to a hybrid committee, subject to conditions that no expenditure shall be sanctioned except for works which are urgently necessary.

PERMANENT WAY.

THE coroner's jury dealing with the accident at Little Bytham, on the Great Northern Railway, which took place on Saturday week, have returned a verdict to the effect that the two persons killed died from injuries caused by the train running off the line because of the subsidence of a part of the track which had been newly relaid, and that their deaths were accidental. A good deal was heard during the inquiry about ballast, and a rider was added to the verdict recommending that slow speed should be maintained until a road was fully consolidated. Thus we have an old question reopened. The relations between speed and permanent way come once more to be dicussed. Yet it might be imagined that the last word concerning permanent way in Great Britain was said years ago. But this is not the fact. The subject is one of permanent interest; questions constantly turn up for discussion, and accidents, such as that to which we have just referred, direct attention to rails, sleepers, ballast, and chairs, when controversy sleeps, and once more battles are fought, and arguments in favour of this, that, and the other are heard, and seem as fresh as if they had not served their purpose already thirty or forty years ago. In our own correspondence columns the construction of permanent way has been recently discussed by Mr. Tratman, Mr. Whitehouse, and one or two other more or less competent authorities. It will be remembered that Mr. Tratman wrote advocating the United States system of flat-footed rails resting on transverse sleepers or "ties," to which the flanges of the rails are spiked. He holds that this makes a better road than the English system provides, and he appears to say that the very high speeds recently attained by trains in the United States are largely due to the small resistance offered by the American railroad. There can be no difference of opinion as to the importance of reducing resistance on railways. It is questionable, indeed, if any expense in reason that can be incurred in improving permanent way would not pay for itself. The only point open to discussion is summed up by asking—What is the road of least resistance?

Before we can answer this question we have to ascertain in what the resistance consists. How is it set up? What is the cause of it? We may leave out of consideration axle friction, because that is quite independent of the road. The rolling friction of a quite hard and cylindrical tire on an equally hard, smooth, and level rail is exceedingly small, almost infinitesimal. If we watch the progress of a locomotive, particularly at a slow speed, along a railway, it will be seen that the rails continuously sink under it as it advances. The leading wheels are always running up hill. We see again that the rails rise behind the tender, so that its trailing wheels are always running down hill. It may be proved that a hard smooth steel roller, passing along a perfectly elastic and yielding surface, will only experience the same resistance as a similar roller would encounter in rolling over a rigid surface, the work done in deflecting the track being repaid by the rise of the track behind the roller. But the permanent way of a railway is not perfectly elastic, and the result of deflection is loss. It is not at all so easy as it appears to be at first sight to explain how deflection is brought about. The rail springs under the tread of the wheel, and the sleepers bend because the ballast immediately under the chairs, would not alone suffice to support the insistant weight; but beyond this there seems to be a process of give and take going on in the ballast, which deserves more investigation than it has received. It would probably be found that all railway tracks after being driven down by the passage of a train rise again, but not at once. It is certain that a weak road is a road of high resistance; but so long as the road is not permanently deflected downwards, the resistance ought to be the same on a stiff and a weak track. That it is not the same is, however, very well known, and it may be taken as proved that the nearer a road is to being absolutely rigid the smaller will be the rolling resistance which it will offer to trains.

On the other hand, it must not be forgotten that an absolutely rigid road would be intolerable to passengers. A certain amount of elasticity must be provided, for reasons very well understood; but where shall it be put? All modern practice says in the sleepers, or at all events in the road somewhere. Mr. Griggs, an American engineer, said thirty years ago that it ought to be be put in the wheels, and he mounted his engine tires on wood blocks. Mr. Mansel said in the wheels, and the wooden Mansel wheel is practically universal in Great Britain today for coaching stock. Mr. Bridges Adams said in the wheels, and he put a steel spring between the tire and the wheel rim. But it must be provided somewhere, and it seems to be of small consequence whether it is in the wheel or the road, provided that it is as nearly perfect as possible. The range of resiliance may be very small, and appears to be provided by the normal system of sleepers and chairs in sufficient quantity. Granting this, it follows that the stiffer the road the less will be the resistance. Now the flange rail, it is easy to see, cannot be, weight for weight, as stiff as the bullhead. The stiffness of a rail varies within normal limits as the square of its depth, but a flange rail cannot be as deep as the bullhead if the weight of the two is the same per yard. The metal of the flanges is provided at the expense of the web; the result is that the first-class roads in the United States are laid with rails weighing as much as 100 lb. to the yard, and the sleepers are broader and closer together than they are in this country. The attempt is made to compensate for the lack of vertical stiffness in the rail by using many sleepers. It is not at all difficult to see why the system finds favour in the United States. In the first place, timber is very cheap there as compared with its cost in this country. Probably if we take the whole system of the United States it will be found that sleepers cost less than one-half what they cost in England. In many districts — round New York, for example — they are no doubt expensive, but in the forest country their value is almost nominal. Again, the cost of cast iron in the United States is so considerable that chairs would probably represent double the outlay on an American as compared with an English line. We have very little doubt but that the permanent way in each country is that which gives the highest efficiency for the smallest outlay—in other words, the road which, on the whole, is found most suitable to the requirements of the traffic and the pockets of the shareholders. It must be conceded, however, that small differences in the details of construction can have little or no influence on dividends. It is not only possible, but right, to look at all questions connected with permanent way from the profit-and-loss point of view. The engineer is, of course, prone to consider the questions at issue as of mechanical or technical interest only; but this is not right. After all, that road is the best which gives the largest dividend. It is no doubt true that the better the road, other things being equal, the better the dividend, but it is not always easy to see how or why.

Fresh interest is imparted to the whole subject by the augmentation of railway speeds. It is true that a high speed is as safe, or safer, than a slow speed, but only because the fact that high speeds are possible implies that the road and the rolling stock are alike excellent. It has been stated, and no doubt truly stated, that the very high speeds attained in the United States by certain trains are brought about not only by the great power of the locomotives, but by the extraordinary excellence of the permanent way. There is not the smallest chance of a radical change being made in the construction of permanent way in this country. The cross sleepers and chairs leave nothing to be desired; but it is not to be denied that, while there are hundreds of miles of road in Great Britain superlatively excellent, there is not a little of it open to improvement, and, if very high speeds are to be regularly attained and maintained, the improvement will have to be made. In what it will consist is very easily stated. Rails must be made deeper and stiffer. In the course of a few years we do not doubt that a bullheaded rail, weighing 100 lb. to the yard, will be the standard rail on our principal lines. We do not think that any change in the sleeper will be needed, but beyond question ballasting is not what it ought to be in all cases. The question of ballast is very important. It is not often that railway companies will lead it in quantity for long distances. What is to be had in the neighbourhood is used. In one place we find excellent gravel; in another, broken stone, in another chalk, in another only inferior gravel, or sandy clay, which runs into mud in wet weather, and flies into dust in dry. The attempt to make a profusion of sleepers compensate for bad ballasting is equally common and futile. Very large sums have been expended on many English lines in improving track, but a good deal remains to be done. The advent of the steel rail enabled locomotive superintendents to place loads on their driving wheels which would have reduced iron rails to the condition of a besom in three months; but it must not be imagined that the steel rail, unless it is backed up by good ballast, can carry the load of eight and nine tons on a wheel now common enough. Shareholders may reconcile themselves to the fact that heavy trains and great speeds mean superlatively excellent permanent way; as good as can be, not only in rails, chairs, keys, and sleepers, but in the ballast, on which ultimately devolves the duty of supporting not only the train, but the sleepers and rails as well. The stiffer the rail the greater is the area of ballast over which the load is spread; but the distribution can only be got at the expense of deflecting the rail, and the more the rail bends, as we explained at the outset, the greater the train resistance. Indeed, under certain conditions, almost the whole rolling resistance is due to the bending of the rails under the load placed on them.

BEST YORKSHIRE IRON.

The announcement that the Bowling Iron Company, of Bradford, Yorkshire, have given up the manufacture of rolled iron, and are dismantling all the machinery and plant used for that purpose, marks an epoch in the iron and steel trade of this country. It is evident that there is not enough for all those—limited in number as they are—who are engaged in the trade; the "survival of the fittest" will doubtless leave sufficient manufacturing power still available. Those who remember, in the days before steel boilers, how the old specifications used to run, "The furnaces must be of Lowmoor, Farnley, or Bowling iron," will realise the change now that the use of steel is all but universal. It must not be supposed, however, that iron plates of high quality are a thing of the past. The advantages of steel over iron are superior strength, great ductility in manufacture, and cheapness. But these advantages to the maker and in regard to price to the user also, do not settle the whole question. Endurance against fire, especially in the furnace plates; resistance to corrosion from impure water, facility for repairs have also to be considered, and in these respects "Best Yorkshire Iron" still holds its own in the estimation of many well able to judge, and who back their opinion by paying the higher price of such iron over steel. In regard to bar iron, although there have been changes in the same direction, steel has not ousted iron to the same extent as in plates. For safety in welding and for resistance to sudden shocks, the iron affords a security not yet attainable from steel; and although in Germany and elsewhere steel under the euphonious name of "flusseisen," or ingot iron, is used, engineers—at any rate, British engineers—who are acquainted with its origin do not trust it. This is evidenced by the fact that for such purposes as the draw gear of railway locomotives and carriages, the parts of traction engines subject to twisting strains, stay bolts for steel fire-boxes, and the welded frames and suspending shackles of pit cages at mines, are still made of "Best Yorkshire," though it costs double the price of ordinary iron or steel. In distant countries, where the cost of freight, duty, and inland carriage and expensive skilled labour enhance the cost of forgings, the fact that the iron has in England cost 1d. per pound more than ordinary iron, is not prohibitory for forgings whose total cost is 1s. or 2s. per pound.

The method of manufacture of this iron, well known as it is to those who have occasion to visit the works, may be shortly described. The clay-band ironstone found in the "black bed" collieries between Leeds and Bradford was found as early as the beginning of this century to afford the material for rolled iron of the best quality, and at Lowmoor as well as at Farnley and Bowling a staple manufacture of great importance to engineers was established. Doubtless much of the superiority of the pig iron made from this ore lies in the fact that it is made in cold-blast furnaces, a process which rejects into the slag or dross much of the impurity which in ordinary hot-blast furnaces passes into the pig. The fact that the pig iron made by the above-named firms is sold to iron-founders, who use it for special purposes, at prices more than double those of Scotch pig iron is evidence of its value. The next stage in the manufacture is the refining, the pig iron being melted in open fires, from which it is run into shallow moulds. The boiling and aërating in these processes free the iron from silica and other impurities. The refined iron is then puddled, and there are elaborate subsequent processes of hammering, piling, and rolling. The superiority of this iron does not lie in any great tensile strength. In plates, 22 tons per square inch longitudinally, and 20 tons crossways is usual, the iron when stretched cold extending from 15 to 25 per cent. longitudinally in a length of 4in., and from 10 to 15 per cent. crossways, and showing a reduction in sectional area at the place of fracture of from 15 to 20 per cent., and 10 to 15 per cent. respectively. In bars the strength ranges from 23 to 25 tons, according to the size of section, the extension 20 to 40 per cent. in 4in., and the reduction of area from 30 per cent. in a bar 3in. diameter to 50 per cent. in a bar of 1¼in. diameter. It is this combination of ductility with strength and toughness which gives evidence of quality, and cannot be equalled except with iron smelted entirely with charcoal, and finished also with similar fuel.

In these modern days, when lofty furnaces stimulated by a high-pressure hot-blast pour out the full product of the ore, it is interesting to watch the old process which still exists. At Farnley, Leeds, within the city boundaries may be seen the ore as it is taken from the adjacent pits, the old-fashioned stone-built blast furnaces, and the whole sequence of operations down to the finished plate or bar. Messrs. Taylor Bros. and the Monkbridge Company, both of Leeds, are also makers of best Yorkshire iron, they carrying on this trade in connection with the manufacture of steel wheels and axles.

◆◆◆

THE COAL TRADE.

The miners' agents are consistent. They keep telling their clients, the colliers, that the coal trade is not so black as it is painted. One of them, Mr. W. E. Harvey, Assistant Secretary to the Derbyshire Miners' Association, wants to be told why Mr. Emerson Bainbridge, M.P., is purchasing every acre of coal he can come across if the coal trade is in such a bad way. Other agents are anxious to know how it is that Sir William Armstrong's firm, the Sheffield Gas Company, Messrs. Vickers, Sons, and Company, Messrs. Cammell and Co., Sheffield, and others, can pay such large dividends if the coal business is so bad? A little light on this point may be desirable. Mr. Bainbridge, who has a very large holding in coal, was clear-headed enough a long way back to see that profitable business in the future must be with the large well-equipped collieries. That accounts for his enterprise in fresh coalfields, and arranging for the bringing to bank of coal in great quantities, by means of the most improved machinery, at the lowest possible costs. There is no other secret attached to Mr. Bainbridge's action in acquiring large areas of coal for work in the future. As for Sir William Armstrong's firm and the great Sheffield establishment of Cammell and Company, the profits there are not made from coal, but from everything except coal. If it were possible to separate the results of the operations carried on in both concerns, it would be found that coal resulted in a loss, which had to be recouped from the more remunerative iron and steel industries. It is quite true that at the recent meeting of the Sheffield Gas Company, Sir Frederick Mappin, M.P., the chairman, announced that during the year the company's coal bill had been rather over £1000 less. But the Sheffield Gas Company are not coalowners, they are coal buyers, and their case is precisely the argument of the coalowners that the values have gone down, while wages have remained at the old standard. It is perfectly true, as Mr. Bainbridge says, that only one colliery out of every three in the Yorkshire and Midland districts is paying, and whatever the miners' agents may say, there must be some re-arrangement in regard to wages before the Conciliation Board can be continued. The Rosebery arrangement expires at the end of July, and if both parties to it are stubborn in declining to give and take, the Conciliation Board will come to an end. In that case, the evil of competition, which the miners' agents are so eloquent about, will be accentuated. No common agreement will then exist as to prices and wages. Each man will do the best he can for himself, and the outcome cannot possibly be for the benefit of the coal getter. He knows, or he ought to know, that the country has never yet recovered from the coal war of 1893, that contracts have gone abroad which have not returned and are not likely to return, and that although more coal is brought to bank, less men in the future will be required to get it there, for every year sees mechanical appliances perfected for the diminution of manual labour, while the people who wish to go down the pits are continually becoming a larger host. The collier, if quite content to work three days a week at 15 per cent. to 20 per cent. more than his brethren get elsewhere, will probably find, at a time not so far off as he thinks, that even that modest amount of work cannot be found for him. What then?

CALEDONIAN RAILWAY EXTENSION.

At the present time, in several respects, the Caledonian Railway Company is more active than are most of the companies in the north. It is expending a large amount of capital, both on the lines that are open for traffic and on those that are in course of construction. In its past half year, the expenditure on capital account was £357,589. The largest item was that of the expenditure on the Glasgow Central Railway, which took £154,717 out of the total just stated; and another line in course of construction—the Follcross and Newton branch—claimed a further sum of £34,358. On the lines open for traffic £36,873 were spent, and on additional working stock £103,421, whilst the amount spent on lines that are authorised, but not yet under construction, took the main part of the balance. In the current half year, an increased rapidity of construction is evident. On the Glasgow Central Railway £154,312 is expected to be spent, on the Dumbarton and Balloch line £12,000, and other works bringing the amount for lines in course of construction to

£240,154, as estimated. On lines authorised, but not yet commenced, it is anticipated that in the current half year the expenditure will be £83,968, and that there will be thus a start made with some of the deferred lines. On working stock, the estimate is that £140,447 will be spent, and, with smaller sums, the total estimate for the half year is £551,105. It will be seen that the Glasgow Central Railway is claiming a large amount of money, but it is now coming into use, the Rutherglen and Glasgow section having been used since last November for passenger traffic, whilst the Kelvindale branch has been employed for mineral and goods traffic. After the end of the current half year, the total estimated expenditure of the Caledonian Railway is put at £1,586,730. The company has still a large amount of unproductive capital, but as the branches named are brought into use, and as the other works yield a larger revenue, there will be made lucrative some at least of the large sums that have been spent in extending the Caledonian Railway in the past few years. That extension is progressing, and it should soon yield to the Caledonian an increased revenue. That great Scotch railway now more fully fills its large and varied area, and with a period for rest after the completion of the works it has now on hand, it should yield better returns to its owners even than it has done of late.

LITERATURE.

Elektrische Kraftübergung im Bergbau. 8vo, pp. 76. Siemens and Halske. Berlin: 1896.

THIS is a large pamphlet or descriptive memoir on the application of electricity to the working of machinery in mines from sources of power at a distance, as carried out by the author's firm in several mines in Germany and other countries. The descriptive part, which is essentially of a popular character, deals first with the different classes of electro-motors and generators, their characteristic advantages and defects, &c., methods of reducing sparking in reversal, &c.; and then proceeds to a description of the methods of adapting the power to the different operations of pumping, ventilating, winding, and haulage and boring. In this part the co-operation of Mr. C. Hoppe, a well-known builder of winding machinery, has been secured for many of the designs which are given in the accompanying illustrations. These include pumping plant, suitable for all kinds of work, from lifting a few gallons of water from the bottom of a dip heading to the largest deep pit work requiring 250-horse power to drive it. Among these, the working pumps, which are both of the centrifugal and reciprocating kinds, are remarkable for the ingenuity of their design. On page 45, a very compact design for a ventilating fan is given, in which the field magnets of the motors are fixed to the casing, while the armature and fan run on the same shaft. The winding machines are mostly intended for underground use, on inclines, &c., and are comparatively small, many of them being from examples actually erected, and the same may be said of the haulage plant, which includes examples of both endless rope and chain systems. The boring machines are of two kinds—one of them, for soft ground, is of the screw auger or "Ricketty" class, while the other is percussive in action, although driven by a rotary motor, with a fly-wheel. This machine is not otherwise described than by reference to an account published in the *Electrotechnischer Zeirtschrift* for 1895; but from what we can gather in the present notice, it appears to be somewhat similar in principle to the Jordan rock-drill, springs being used, instead of an air compressor, for giving the blow. The work done by this machine seems to be very considerable for a small consumption of power, from 3in. to 4in. per minute of a 1·4in. hole in hard granite or quartzite with 1-horse power effective; and, judging from the illustrations, the plant is extremely compact, the motor being enclosed in a small box, and transmitting the power by a flexible strap. The examples illustrated are to a great extent taken from photographs of the machines actually at work underground, which adds considerably to their interest and value. These are principally from installations erected by Messrs. Siemens and Halske at the salt mines of Aschersleben, which, unfortunately, have within the last year been totally lost by the swamping of the mine through an influx of water in the shaft; from Prince Hohenlohe's Pauline shaft at Kattowitz, where an extensive dip haulage plant has been erected on an inclined seam; and the Ashiel Mine in Japan. The latter plant includes a power station, with five direct current 625-volt generators, each driven by a Pelton wheel of 150-horse power, which is applied to pumping, winding, and dressing machinery, as well as furnishing the power for a locomotive haulage. Among other works in course of execution may be mentioned a ventilating fan at the Ferdinand pit at Kattowitz, which is to be driven by a motor of 110-horse power about a thousand yards away from the source of power; a power station with two 500-horse generators, giving a current of 2000 volts at the Ilse Lignite Mine and Brickworks in Lusatia; and the Rand Central Electric Works in the Transvaal. The last, which is one of the most important plants of its class, is intended to supply current to the gold mines on the Rand from a colliery about thirty miles distant. The generating station is to contain four alternators, together of about 4000-horse power, giving a current for transmission of 10,000 volts tension.

A Text-book of Gas Manufacture for Students. By JOHN HORNBY, F.I.C. Small 8vo, pp. 261. London: George Bell and Sons. 1896.

THIS work is intended to provide a manual of gas manufacture suitable to the requirements of young men starting their training in gas works, and also to serve as a text-book for the use of students preparing for the examinations of the City and Guilds Institute on the subject of gas manufacture; it being for the latter purpose made just to cover the ground included in the syllabus on which the examinations of that body are based. Keeping these objects in view, the author has classified the whole field of gas manufacture under different headings, which are systematically surveyed in a series of short chapters, starting with the composition of coal, and passing through the various operations of carbonising, condensing, purifying, working up of residuals, storage and distribution, measuring, and so on, until the consumer's requirements are studied in the forms of burners, penny-in-the-slot meters, &c. The treatment, though necessarily somewhat sketchy on account of the limited space at command, is, as a whole, well suited to convey a clear idea of the essential principles of the manufacture to beginners, and the author is to be commended for having devoted himself mainly to the more important technical points, which are, therefore, more fully described than would have been possible with a wider range of subjects. The section on condensing and purifying processes and those on the relation between temperature in carbonising and the quality of the gas and residual products are very well done; but that on the primary operation of carbonising, considering its importance, would be better for a little stronger handling, especially as regards illustrations. The figures representing retort settings and furnaces are far too small and indistinct to be of much descriptive value, and this is the more to be regretted as the illustrations in all the other parts are exceedingly good.

The quantitative analysis of gas as practised in the works is not noticed, as that has formed the subject of another book by the author, but a reference to it, as well as to the larger detailed works on gas making, is made in the introduction; and some specimen examination papers of the City and Guilds Institute in gas manufacture given in an appendix serve to complete the book, which is likely to be of considerable value to others, as well as to the class of students to whom it is specially addressed.

SHORT NOTICES.

The Wood Industries of Sweden. London: *The Timber Trades' Journal.* 1896. Price 2s. 6d. This contains articles on the saw and planed wood trade, forest exhaustion in Norland, the firewood trade, squared timber and balk trade, the joinery trade, the Gothenberg district, the Stockholm district, the small ports of Gefle, and on ten of the great timber producing districts of northern Europe.

Handbook for Laying Out Curves on Railways and Tramways. Calculated for every possible Angle and Radius. By G. H. A. Kröhnke. With one plate. London: Kegan Paul, Trench, Trübner, and Co., Ltd. Price 5s. This is the ninth edition of a book which leaves those who are acquainted with it very little or no calculation to do in setting out any curves of any length or radius.

Aluminium. Manchester: The Aluminium Supply Company.—This little book, issued by the above-named company, which is the agent of the Pittsburgh Reduction Company, is a good deal in advance of most brochures published for trade purposes. The statements of the advantages of aluminium are not grossly exaggerated, and the whole tone of the book is candid and free from objectionable puffery. It contains many useful data, which, taken generally, are reliable and rest upon modern observations, and indeed its single noticeable fault is the use of the atrocious coinage "alium"—which means garlic, if anything—as a substitute for the word aluminium.

Tabulated Weights of Angle, Tee, and Bulb Iron and Steel, and other Information for the use of Naval Architects, Shipbuilders and Manufacturers. By Charles H. Jordan, M.I.N.A. Fifth Edition. Revised and enlarged. London: E. and F. N. Spon. 1896. Price 7s. 6d. This very comprehensive set of tables now extends to 578 pages, and gives the weights and the sectional areas and all dimensions of all known forms of rolled channels, angles, bars, tees, bulbs, rails and sheets of iron and steel; and other information, including metre weights, tonnage matters, relating to equipment of steam and sailing vessels, and other collateral information, which is of frequent usefulness to those most concerned with the employment of these materials.

The Cyclist Year-Book for 1896. Edited by Henry Sturmey. London: Iliffe and Son. Price 2s. net. This year-book, of 182 pages of text and 95 pages of advertisements, is a remarkable illustration of the greatness of the manufacturing industries supported by the patrons of the cycle in different forms. It contains a *résumé* of the cycling events of the past year, records of the feats of the English and foreign amateurs and professionals, both on the path and on the road; tables of speed per hour, second and lap; particulars of the National Championship of the World, descriptions of the new things in cycle construction for 1896, shows statistics for 1895, cycle company returns, applications for cycle patents, foreign tariffs on cycles and cycle materials, trade directories, cycling clubs of Great Britain and Ireland, and cyclist sections attached to volunteer regiments. It is a year-book useful to the cycle trade and cyclists generally.

THE ELEMENTS OF FORCE IN WARSHIPS.

ADMIRAL COLOMB read a paper on the question of estimating the fighting powers of warships, in the United Service Institution, with Lord Northbrook in the chair, on March 18th. This paper we regard as very important. The author has brought together a quantity of valuable data which he has classified in various ways, and if he has presented it to us for our use before he has drawn all the lessons which he might have done in course of time had he kept it all to himself, we are all the better treated. The paper was accompanied by a number of tables showing the elements of power in various branches—displacement, number of guns, energy of fire for one round per gun, energy of fire per minute, energy per 1000 tons displacement, shell charge per round per 1000 tons displacement, inches of calibre of guns per 1000 tons, weight of metal discharged, weight of armour, coal supply, speed, &c.; and tables in which these and other elements are combined so as to give powers of offence and defence.

Admiral Colomb explained and reviewed the work which he had thus performed. He referred to an effort made by Captain Noel to assign proportionate value to many of the same elements dealt with in this paper. He considered, however, himself, that such valuation must of necessity be completely arbitrary, and probably would be agreed upon by no two competent men. Moreover, from time to time circumstances would arise which would cause more weight to be given to some in contradistinction to others. In this condition of things the author thought it best to limit his work in the main to comparing the powers of our English types in each aspect, leaving the relative weight to be given to each element open. We are glad to say that in the important matter of fire Admiral Colomb uses the same measure that we employed in an article last November; that is to say, the total energy of fire delivered per minute. It is satisfactory to find so high an authority adopting the same measure perfectly independently, probably before our article was published. The figures do not agree because he gives a greater rate of fire to the light guns, but such a difference as this is easily disposed of. Admiral Colomb also seems to consider that a given amount of shell-fire will tell more for its particular purpose of attack of lighter structures if delivered in several small shells than in one large one. The author, as noticed above, spoke of the great difficulty he experienced in endeavouring to shape and classify data, giving weight to the various elements, but many bore a certain sort of proportion to displacement. The question of the relative value of a given energy of fire delivered by a few heavy guns, as compared with the same from a number of medium quick-fire pieces, was considered, and eventually the case of two Edgars attacking one Majestic. The scope of the paper, however, was such as does not admit of doing justice to it in a short notice. A discussion followed, in which Sir John Hay and Sir Edmund Freemantle took part; but it was evident that the subject was too fresh for any mature opinions to be expressed.

INSTITUTION OF NAVAL ARCHITECTS.

THE following programme has just been issued for session 1896:—The meetings will be held as follows:—In the Hall of the Society of Arts, John-street, Adelphi—by kind permission of the Council—on Wednesday, March 25th, morning at 12 o'clock; on Thursday, March 26th, morning at 12, and evening at 7 o'clock; on Friday, March 27th, morning at 12. The Right Hon. the Earl of Hopetoun, G.C.M.G., President of the Institution, will occupy the chair.

The Council of the Institution will meet in the Library of the Society of Arts, on Wednesday, March 25th, at 11 a.m., and on Friday, March 27th, at 11.15 a.m.

PROGRAMME OF PROCEEDINGS.

Wednesday, March 25th.—Morning meeting, at 12 o'clock: (*a*) Annual report of Council; (*b*) election of the president, the officers, and Council; (*c*) address by the chairman, the Right Hon. the Earl of Hopetoun, G.C.M.G. The following papers will then be read and discussed:—(1) "Water-tight Doors, and their Danger to Modern Fighting Ships," by Captain the Right Hon. Lord Charles Beresford, C.B., R.N. (2) "Water-tight Doors," by Colonel Nabor Soliani, Director of Naval Construction, Royal Italian Navy, Member. (3) "Some Geometry in connection with the Stability of Ships," by J. G. Bruhn, Esq.

Thursday, March 26th.—Morning meeting, at 12 o'clock: (1) "The Causes of Mysterious Fractures in the Steel used by Marine Engineers as revealed by the Microscope," by A. E. Seaton, Esq., Member of Council. (2) "The Measurement of Feed and Circulating Water, &c., by Chemical Means," by C. E. Stromeyer, Esq., Member. (3) "Salvage Appliances," by J. G. Kinghorn, Esq., Member. Evening meeting, at 7 o'clock: (1) "Compound Marine Boilers," by Colonel Nabor Soliani, Director of Naval Construction, Royal Italian Navy, Member. (2) "Water-tube Boilers," by J. Watt, Esq., Member. (3) "Circulation in Water-tube Boilers," by Professor W. H. Watkinson.

Friday, March 27th.—Morning meeting at 12 o'clock: (1) "The Non-uniform Rolling of Ships," by R. E. Froude, Esq., F.R.S., Associate Member of Council. (2) "A New Theory of the Pitching Motion of Ships on Waves, and of the Stresses produced by this Motion," by Captain A. Kriloff, Professor at the Naval Academy of St. Petersburg. (3) "Notes on the Carriage of Grain Cargoes," by George Herbert Little, Esq. (4) Concluding proceedings.

The annual dinner of the Institution will be held on Wednesday, March 25th, at the King's Hall, Holborn Restaurant, High Holborn, at a quarter-past seven. Tickets 7s. 6d. each, which will be paid for at the dinner. Evening dress.

Note.—The Chairman will, if possible, arrange for an interval of about forty minutes for luncheon at each morning meeting at 2 p.m., or as near that hour as the state of business will permit.

LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.—The forty-third anniversary dinner of the Association will be held in the Great Hall, Cannon-street Hotel, on Saturday evening, April 25th; chairman, Mr. John Wolfe Barry, C.B., F.R.S., vice-president, Inst. Civil Engineers.

THE BRITISH ASSOCIATION OF WATERWORKS ENGINEERS.—A full meeting of the Provisional Committee was held at the Westminster Palace Hotel, on Saturday last, for the purpose of finally revising the constitution and rules. These will be published shortly, when a general meeting of the association will be duly announced.

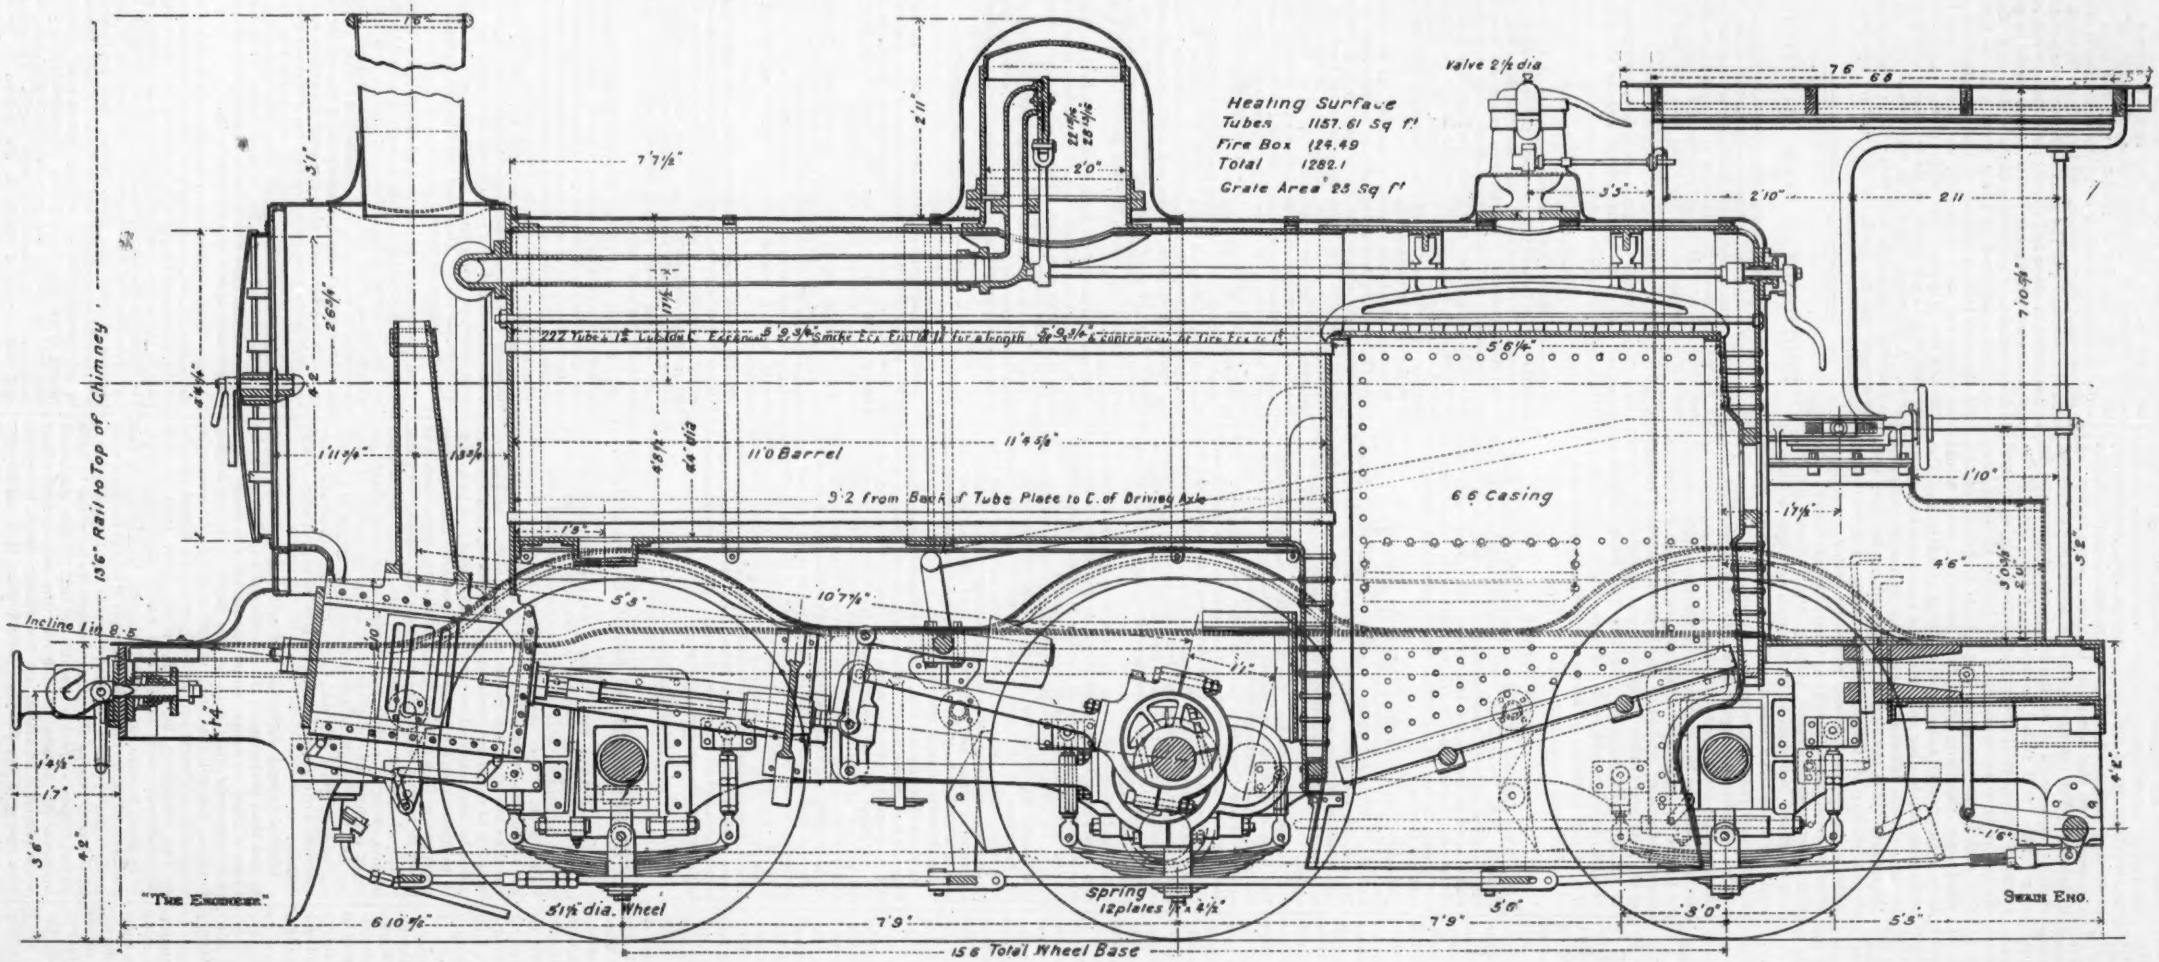
TRADE AND BUSINESS ANNOUNCEMENTS.—We learn that Messrs. William Simons and Co., Renfrew, have received an order from the Mersey Docks and Harbour Board for the construction of a large and powerful stationary barge-loading dredger, similar to the Walter Glynn recently constructed, this being the eighth dredging vessel ordered from William Simons and Co. by the above-mentioned Harbour Board.

THE FASTEST BOAT IN THE WORLD.—Messrs. Thornycroft and Co. have succeeded in producing a vessel which is not only the fastest vessel in the world, but has attained that position almost at her first effort. It is well known that as a rule fast vessels are worked up by degrees to their maximum speed, small alterations being usually required in the fitting of the valves, amount of grate, trim of boat, area of propeller, &c. But on Tuesday the Desperate torpedo boat destroyer, designed and built by Messrs. J. Thornycroft and Co., ran a preliminary trial, and obtained a mean speed, on four runs on the measured mile, of 31·035 knots, or 35¾ statute miles. The speed was taken by Admiralty officials, and is the highest on record.

THE BIRMINGHAM ASSOCIATION OF MECHANICAL ENGINEERS.—At the March monthly meeting a paper was read by Mr. A. Calvert on "Capstan Lathes, their Construction and Utility," the synopsis being plain and semi-automatic capstans, embodying a description of wire feeds, turret feeds, and chasing arrangements, &c. After giving a detailed description of the capstan lathe as an up-to-date machine tool, and explaining the various devices which have been introduced, he stated that the Americans claimed to be the inventors of these machines, but such lathes were used in the Government factories in England before they were seen in America. As an instance of the utility of these lathes, he stated that an article which he knew cost 2s. 8d. to machine on an ordinary lathe, was now done upon a capstan lathe for 4d.

KING'S COLLEGE ENGINEERING SOCIETY.—On Friday, March 13th, Mr. Sodean, B. Sc., read a paper on "Gases as Illuminants." The author commenced his paper by explaining the action which takes place in the several parts of the flame of an ordinary gas flame. The thermo-couple was explained in detail, and its use in determining approximately the ranges of temperature of the various portions. Figures were given showing these temperatures. The acetylene flame was shown, and its richness in carbon was also shown by experiments with the ordinary Bunsen burning coal gas, with varying proportions of acetylene. The manufacture of acetylene from calcium carbide was gone into thoroughly, and the cost of manufacture was discussed at some length. The paper terminated with a vote of thanks to Mr. Sodean for his interesting paper.

CONTRACTS OPEN—LOCOMOTIVES FOR THE EASTERN BENGAL STATE RAILWAY



CONTRACTS OPEN.

LOCOMOTIVES FOR THE EASTERN BENGAL STATE RAILWAY.

The Secretary of State for India in Council is inviting tenders for sixteen goods engines and sixteen tenders for same, also duplicate parts, viz., two sets of wheels and axles, with crank-pins, &c., and two sets of springs. The engines are to have six wheels, all coupled, inside cylinders, and inside frames, and separate tenders on six wheels; gauge of rails 5ft. 6in. Wherever the specification differs from the drawings the former is to be followed. The weight must not exceed 15 tons on any pair of wheels, as this is the maximum sanctioned by Government. The general dimensions and capacity of the engines and tenders are as follows:—

Engines.

Diameter of cylinder, inside	1ft. 6in.
Stroke of piston	2ft. 2in.
Centre of cylinder to centre of driving axle	10ft. 7½in.
Length of boiler barrel between tube plates	11ft. 4⅝in.
Diameter of boiler barrel outside	4ft. 5in.
Length of fire-box casing outside	6ft. 6in.
Width of fire-box casing at bottom outside	4ft. 6in.
Width of fire-box casing at centre outside	4ft. 6in.
Height of centre of boiler from rail	7ft. 10in.
Number of tubes	222
Diameter of tubes outside	1¾in.
Heating surface of tubes	1157·61 sq. ft.
Heating surface of fire-box	124·49 sq. ft.
Heating surface, total	1282·1 sq. ft.
Fire-grate area	23 sq. ft.
Working pressure of boiler	160 lb.
Length of engine frames	27ft. 7⅝in.
Thickness of engine frames	1⅛in.
Distance between engine frames	4ft. 9in.
Diameter of wheels on tread	5ft. 1½in.
Distance between centres of wheels, leading to driving	7ft. 9in.
Distance between centres of wheels, driving to trailing	7ft. 9in.
Total wheel base of engine	15ft. 6in.
Height of buffers from rail	3ft. 6in.

Tenders.

Number of wheels	6
Wheel base	12ft. 6in.
Diameter of wheels on tread	3ft. 7½in.
Distance between centres of journals	7ft. 8in.
Thickness of frames	¾in.
Length of frames	19ft. 4⅝in.
Distance between frames	6ft. 7½in.
Capacity of tank	2500 gallons
Capacity for fuel	285 cu. ft.

The frame plates of both engine and tender, and all other plates, angles, &c., also rivets, are to be made of Siemens-Martin acid steel of the best quality.

Gun-metal, when not otherwise specified, is to be composed of the following mixtures:—

	Copper.	Zinc.	Tin.
General	8·0	Nil	1·0
Axle-boxes, connecting and side-rod brasses	84·2	1·3	14·5
Slide valves	85·9	0·7	13·4
Glands and their bushes	85·3	2·7	12·0

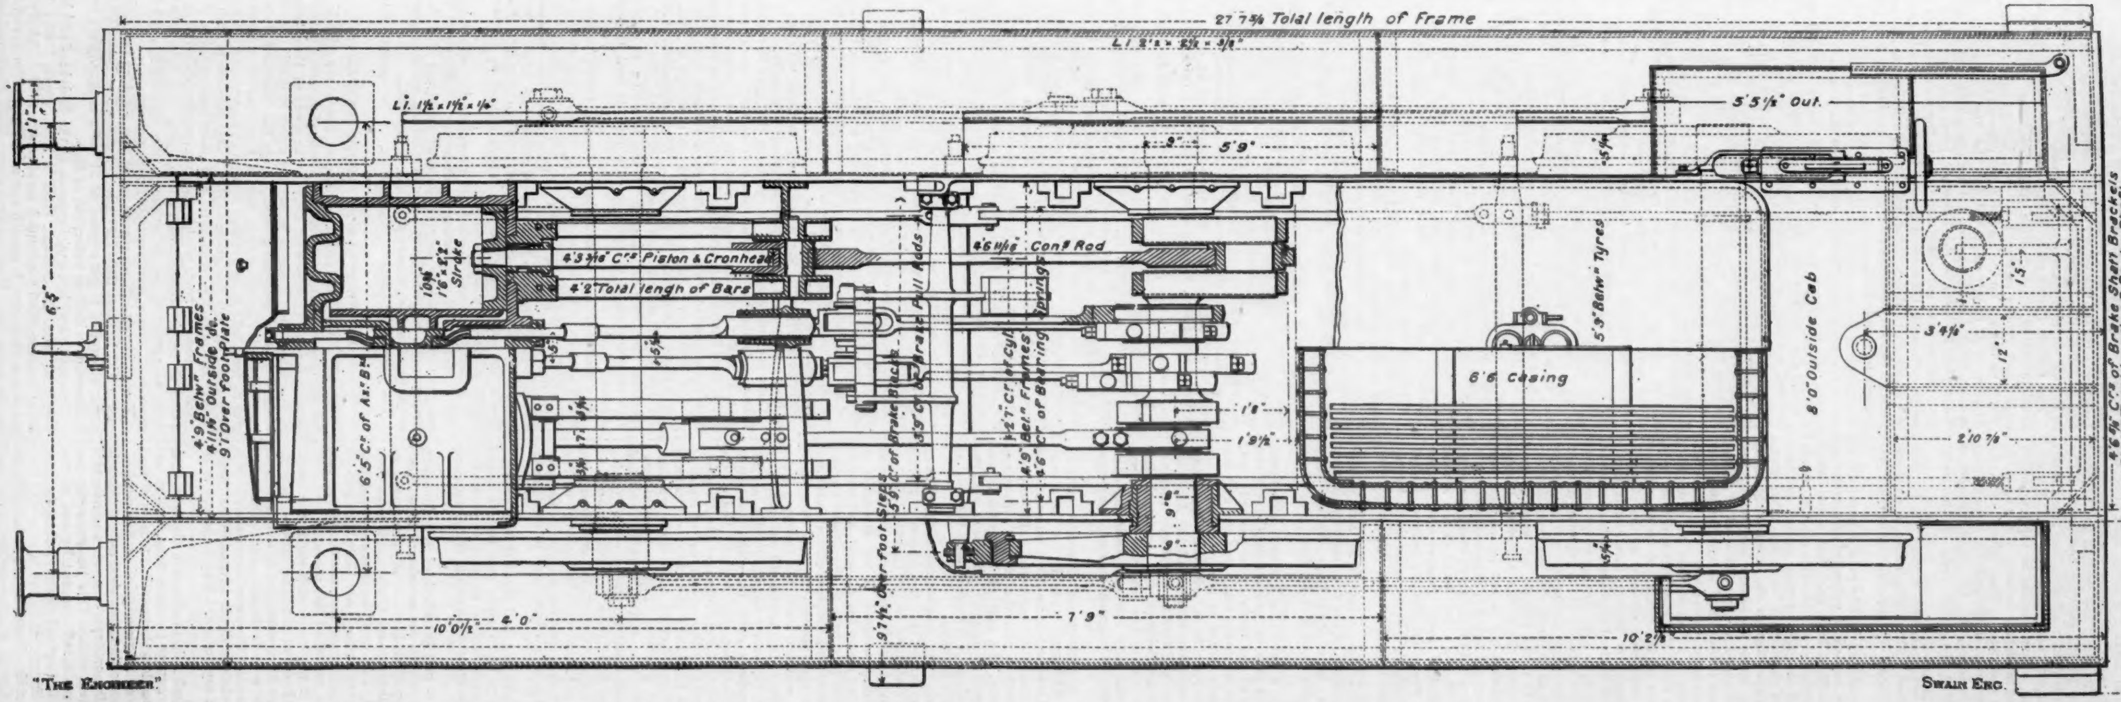
White Metal.

	Copper.	Zinc.	Tin.	Antimony.
For axle-boxes	5·8	64·8	29·4	Nil
For slide valves	7·7	Nil	82·1	10·2

The boiler steel must be capable of standing a tensional strain of not less than 25 tons or more than 30 tons per square inch, with an elongation of not less than 23 per cent. in 10in. Samples, both when cold and after heating to a cherry red and cooling in water at a temperature of 82 deg. Fah., whether cut lengthwise or crosswise, must stand bending double round a curve the diameter of which is not greater than the thickness of the test piece. A specimen for the drift test must be machined for each set of barrel and casing plates to a width of 3in., a ⅝in. hole will then be bored 1¼in. from one end and each side, and must stand drifting until the hole is 1¾in. diameter.

The dome basin is of best Yorkshire iron or mild open hearth acid steel, the flanges are to be scraped steam-tight, and the joints made with boiled oil only. The dome is of 7/16in. steel plate, butt-jointed at the back. A Ramsbottom patent duplex safety valve, with cast iron columns, and gun-metal valves and sections to be fitted to each boiler; valves 2½in. diameter. The top of the fire-box shell is round, and the top and sides are to be in one plate ½in. thick, the front plate is to be 9/16in. thick, and the back plate ½in. thick, lap of plates 3¾in. finished, 13/32in. rivets, 1⅞in. pitch. The upper part of the back plate of fire-box casing is stiffened by a ½in. steel plate, and is connected to the front tube plate by eleven longitudinal stays, 1⅛in. diameter, thickened to 1¼in. at the tube plate, and 1⅜in. at the back plate. Eight belly stays are to be rivetted to the barrel plate and fixed to the copper tube plate. The crown plate of the fire-box is stayed with eight cast steel bars, secured to crown plate by bolts tightly tapped into the roof bars. Distance pieces are cast solid with the bars, and tapped to receive the bolts, these distance pieces must be machined where they bear on the crown plate. The roof bars are to be attached to slings, each made from a single piece of mild steel, fixed to T steels; each roof bar must also stand a load of 16 tons applied on the top, at the centre of the bar, when placed on bearings at its extreme ends in their working position without any set. The tubes are No. 11 B.W.G. thick at fire-box end, and No. 12 B.W.G. at the smoke-box end, 1¾in. external diameter, reduced at the copper tube plate to 1⅝in., and expanded in the front

CONTRACTS OPEN—LOCOMOTIVES FOR THE EASTERN BENGAL STATE RAILWAY



tube plate to 1⅜in., made of a mixture of 70 parts copper and 30 parts of best Silesian spelter. All the tubes must be tested internally by hydraulic pressure to 600 lb.; the ferrules are 1¼in. long, with a taper of 1 in 20, made of best quality steel tube.

There are twenty-three wrought iron fire-bars spaced 1⅛in. apart. The ash-pan is of ¼in. plate, provided with a door at the front and back ends, both worked from the foot-plate; meeting surfaces of doors and seatings are to be machined and faced to secure an air-tight fit. The smoke-box is 5ft. 1½in. wide and 3ft. 3⅜in. long inside, it is made of ⅜in. steel; the sides of crown are in two plates; the door is of $\frac{5}{16}$in. steel with a ¼in. protecting plate. The barrel of the chimney is of ⅜in. steel plate, butt-jointed at the back, with an inside butt strip. Two of Gresham and Craven's most recent pattern of horizontal combination injectors, one No. 7 and one No. 8, made of gun-metal, with all cones made movable for renewal. The internal steam pipe is of copper, No. 5 B.W.G. thick, tested to 280 lb.; the exhaust pipe is to be made of cast iron fitted with Macallam's variable blast pipe. The frames are of Siemens-Martin acid steel, and have a tensile strength of 25 tons to 31 tons per square inch, with 20 per cent. elongation in 10in.; they are of $1\frac{1}{16}$in. in thickness, and need not be planed; all holes marked from one template.

The sand-boxes are to be of steel, the sand is to be led from the boxes by wrought iron pipes, fitted with Gresham and Holt's steam sanding gear. The slide valves are to be made of gun-metal, pistons of tough cast iron, piston-rods forged from the very best open hearth acid steel; connecting-rods are to be I section, forged solid in one length without weld; coupling-rods the same.

The axles of both engines and tenders are to be of the very best open hearth acid steel, and guaranteed to run 200,000 miles for the straight and 150,000 for the crank axles. The axle-boxes are of cast iron, fitted with gun-metal bearings with white metal let in. Axle-box guides are of cast steel; the driving and trailing axle-box guides are fitted with wrought iron wedges case-hardened.

The engine is to be fitted with the automatic vecuum brake complete, of the most recent and approved pattern. The trailing foot-plate is to be of cast iron; each engine is to be erected complete and tried in steam in the presence of the consulting engineer or his deputy. The boiler when finished is to be tested by hot water to a pressure of 240 lb. and by steam to 170 lb. The weights upon each wheel, when the engine is full and light, are to be carefully ascertained separately by a machine which the consulting engineer shall consider satisfactory; the weights must be shown on the drawings prepared by the contractor. The tender is to be filled with water and tested by hydraulic pressure to 5 lb. The remainder of the specification is as usual. No payment will be made on behalf of the contract before 1st April, 1897. Tenders are to be in by 31st inst.

LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

THE BESSEMER PROCESS.

SIR,—A Presidential address has recently been delivered at Pittsburg to the American Institute of Mining Engineers by Mr. J. D. Weeks, who has taken advantage of that prominent position to repudiate my just claims to the steel invention that bears my name, and which has been most amply acknowledged by America's most honoured scientific institutions, manufacturers, and citizens during the last forty years. I may not inaptly preface the remarks I have to make on this subject by the words of our immortal Bard:—

> "Who steals my purse, steals trash,
> 'Twas mine, 'tis his, and has been slave to thousands,
> But he who filches from me my good name
> Robs me of that which not enriches him,
> And makes me poor indeed."

A great moral responsibility is incurred by the man who, for the mere purpose of gaining a short-lived popularity, does not hesitate to blast the reputation of one who he well knows in his own heart is the real inventor of that process which has so enormously extended the trade and commerce of his own country, and for this unworthy object flatters his hearers by telling them that they owe all this to a countryman of their own; taking the opportunity of making these statements at a public meeting at which I necessarily could not be present, and relying for this monstrous accusation upon such vague testimony as he has been able to rake up from bygone transactions touching only one side of the question. Mr. Weeks well knew that a period of forty years, and the wide Atlantic, separates me from all documentary evidence on my side of the case, and which, at the period when all the facts on both sides were before the American people, they had, to their great honour, decided in my favour, and to which opinion they have adhered up to the present day. Fortunately, however, for me, some of the evidence which Mr. Weeks brings forward to support the case of Mr. Kelly, from the very nature of things, furnishes conclusive evidence against the allegations which he makes in favour of Kelly's scheme, and in order that the whole subject may be clearly understood, it is necessary for me to refer to some technical details of iron-making, showing their close analogy with the process said to have been carried out by Kelly.

For the last hundred years or more it has been the practice of manufacturers of malleable iron to operate upon the crude pig iron in a small shallow bath, known as a refinery, or "finery fire," in which the molten pig iron is subjected to a blast of air blown down upon its upper surface from three nozzles arranged along the side of the bath, or pool, of iron, the surface of which has a quantity of incandescent coke floating upon it. After this blowing operation has been continued for an hour or two, the molten matter is to some extent decarburised and partially deprived of its silicon; it is then run out and formed into thick plates, which, when cold, are very hard and brittle white iron; these plates are broken up and reheated in a reverberatory furnace, and rendered malleable by the laborious process of puddling. We hear that a Mr. Kelly was making some experiments of this kind as far back as the year 1847, and we are told by the president, Mr. Weeks, that "Kelly was a forge master making malleable or wrought iron, and it was to make this product that he pursued his experiments," so that, according to the evidence furnished by Mr. Weeks himself, Kelly did not contemplate the production, or even try to produce steel by his experiments, as that material was quite out of his line of business.

But it is cast steel, such as Bessemer invented—and perfected the process of making in every mechanical detail—that has played such an important part in the metallurgy of the present century; it was this cast steel, and not the wrought iron which Kelly was trying to improve, that has laid the 170,000 miles of steel rails like a network over the whole Continent of America; it was this cast steel made by the Bessemer process, and the machinery invented by him, with which the 4,160,072 tons of cast steel was made in America in the year 1872, and not by any plan or device originated or practised by Mr. Kelly.

Now what could be more natural for a forgemaster and manufacturer of wrought iron than to try and save some of the fuel used in the ordinary process of his trade; and what would appear more obvious than the idea that some, or perhaps all, of this incandescent coke lying on the molten pig iron in the "finery furnace" might be saved; this doubtless was the sole and simple object which Kelly had in view when he was trying experiments in his open yard, as described by Mr. Weeks, operating in a very temporary way and using the end of an old boiler lined up with bricks and containing about 500 lb. of molten iron from the blast furnace — just such a charge as when refined would be enough to make a charge for the puddling process which had to follow, and thus to make it into malleable or wrought iron, which Mr. Weeks tells us was Kelly's trade "and what he was trying to make." This was just such an experiment as might be safely made without previously taking the precaution of patenting it, as its value, if successful, would be very small. The apparatus, he tells us, was provided with a single nozzle blowing vertically down upon the metal, and which single jet of air blown down upon it would partially, though very imperfectly, refine it, as is done in the "finery fire" in common use; and when this scheme, which had long been utterly abandoned and forgotten, was investigated some eight or nine years after these experiments had been made, all the evidence which I could collect went to show beyond all reasonable doubt that Kelly was simply trying to make his "finery iron or plate metal" without the employment of any coke floating on the surface, and thus saving some fuel in preparing his metal for subsequent conversion into malleable iron.

This is the impression which was irresistibly forced on my mind at the time these questions were before the American Patent-office, and I have at this moment the most absolutely conscientious belief that Kelly was not at that period even attempting to produce malleable iron or steel in a fluid state, such as could be formed into ingots or castings.

And when we read the strongly biassed statements of Mr. Weeks, and note his all-important omissions, his own story furnishes me with an absolute denial of his most unwarrantable assertion that Kelly had originated the Bessemer process.

Now, one would have thought that if Mr. Kelly commenced his experiments in 1847, we should have heard something of this revolutionary process before the year 1856; but we are told that "as late as 1856, after nine years of work, the appliances he used were exceedingly crude." Mr. John E. Fry, who was a foundry moulder at Cambria when the first experiments were made at Johnston by Kelly, "in a conversation a few days since," thus described the first converter made in 1856, to Mr. Weeks:—

"This apparatus was a 2ft. section of a 3ft. boiler shell, lined up to about 16in. in diameter, having a paved fire-brick bottom about 20in. deep; this was put outside the door of the blast engine-room of the old Cambria blast furnace. The engines gave from 3 lb. to 4 lb. blast pressure; there was a temporary connection made from the blast pipe to this little auxiliary furnace by a gas pipe. The nozzle was a cast iron affair, such as was used at the tuyeres in those days. The tuyere was 'clayed up,' and dried and connected by a loose elbow to the pipe, so as to be swung down into the metal. The metal was melted at the foundry, and brought up in a ladle containing about 500 lb. The furnace was about 200 yards from the foundry, and the ladle was put on to a little metal hauling car, and hauled to the converter; this metal would make probably 8in. or 9in. of depth in this little pot. As soon as the metal was dumped in, the pipe was shoved down with the blast on, a cover of pieces of sheet iron was laid across the top to prevent the sparks flying too freely." And here the evidence drops short, and it is clearly not worth their while to pursue the subject any further, it would be dangerous to do so; it would, in fact, "let the cat out of the bag." These discreet witnesses have given all the very interesting details as to the "dumping" in of the molten iron, even to the kind of "little hauling car" which conveyed the metal to the apparatus; but it would have been infinitely more to the purpose if these observant witnesses had told us something about the way in which this metal was taken out again, in what state of partial or complete solidity did it result, or whether it was soft malleable iron or hard and brittle "plate metal." They have told us nothing of the use of ingot moulds, in which the molten malleable iron must be made into ingot; they have told us nothing of the treatment of the metal after it was blown. Was it taken to the puddling furnace to be there converted into wrought iron, or was it rolled into bars or sheets from ingots formed while in a fluid state? Without all these essential facts ail their testimony and affidavits are worse than waste paper, as they directly prove nothing; but the absence of these facts afford very strong circumstantial evidence that Kelly never had produced homogeneous malleable iron, and had never made an ingot by his process.

Kelly's method of operating by one tuyere only, blowing vertically downward, shows that he had never grasped the fundamental principles on which the Bessemer process is based; his nine years of failure shows that in all that time he had not mastered the A B C of the Bessemer process. Now there is such a thing as blowing and blowing, and, as we are told in the old fable, by simply blowing a man may either "warm his fingers or cool his broth."

But Mr. Kelly saw none of these nice distinctions, and to compensate for this want of knowledge, Mr. Weeks, with much perverted ingenuity, has striven to whittle down the Bessemer process until it is low enough to reach Mr. Kelly's level, and strives to impress on his hearers the idea that the Bessemer process is summed up in the words, "blowing air into iron," and Kelly, having done this, is therefore, according to Mr. Weeks' theory, on Bessemer's level. This, however, is not so; the mere blowing of air into a fluid is not a patentable suggestion, it is not a "new manufacture," and before we can obtain a valid patent we must produce something tangible, something not before produced by the same means, something which is, in fact, either of better quality or less in cost than has been produced by former methods. "I therefore claim as my invention the forcing of currents of air into and among the particles of molten crude iron, or of remelted pig or refined iron, until the metal so treated is rendered malleable and has acquired other properties common to cast steel, and still retaining the fluid state of such metal, and pouring or running the same into suitable moulds," and so obtaining a new "manufacture."

Now blowing air into a fluid mass is not a manufacture at all, and therefore is not patentable; thus, for instance, you may blow heated air into linseed oil, but that is not a new manufacture, such blowing might be simply to warm the oil; but if you blow air in a heated state in numerous divided streams upward from a perforated coil, lying at the bottom of a tall cylindrical vessel filled with linseed oil, the oil so treated will combine with the oxygen of the air and become viscid and tenacious, and will acquire the same drying quality as oil that has been boiled with oxide of lead in the usual way of making drying oils, and hence such a process of blowing air into oil by its chemical action produced a superior drying oil, and was a new and patentable manufacture; this was an invention of mine ten years before I thought of steel-making, and for which invention I reaped my reward.

Again, if you blow cold air in numerous jets upward through a vessel filled with cream, that is in itself not a new manufacture, but if your streams of air are powerful enough, and sufficiently long continued, the violent agitation caused thereby will convert the cream into butter, and result in the production of butter without churning, and thus becomes a new manufacture capable of being secured by patent. The different effects produced by different modes of blowing are well exemplified in the old Catalan furnace used in iron-making, where the tuyere is made carbonising or oxidising by merely altering the angle at which the tuyere is directed through the fuel, and by means of which adjustment of angle the workman regulates his process. Again, in the old "finery fire," the tuyeres blow down on to the metal at such an angle as will throw the metal to the opposite side of the bath, and ensure a rapid circulation of all the metal under operation, without which this old process of "blowing iron" would entirely fail. All this is mere matter of history, but, being known, it serves to show the entire want of ingenuity and mechanical skill, and the complete absence in the mind of Kelly of the most simple and rudimentary knowledge on the subject of the motion of fluids impelled by currents of air, as is clearly shown by his choice of the vertical position of the tuyere, in blowing on to or into fluid iron. Kelly appears to have adhered from first to last to this fatal mistake of using one tuyere only, and that one operating in the very worst position in which it was possible to place it; a position most certain of all others to ensure its own rapid destruction while producing the least possible circulation and effect on the metal. An enormously high temperature is necessary not only to render pure iron fluid, but an excess over that temperature is necessary to allow it to be transferred to a casting ladle, and therein be retained in a fluid state during the time necessary to quietly pour it into numerous moulds. The great problem I had to solve was how to generate and retain this enormously high temperature, for on any system of heating fluids we have two antagonistic operations going on, viz., the production of heat and its loss by radiation and absorption by the vessel in which the process takes place, and this particular case is further complicated by the rapid absorption and carrying off of heat by the incombustible portion of the air forced through the metal, hence it becomes a question of time; heat is always flowing away, and if the accession of heat went on at the same pace, we should never raise the temperature of the metal, and this points at once to the necessity for an extremely rapid production of heat; this rapid production of heat means such an intimate admixture of the combustible carbon and silicon with oxygen as will produce the necessary temperature in a few minutes, otherwise the heat would be dissipated and the fluidity could not be maintained. So intimate is the mixture of carbon and oxygen in gunpowder that its combustion becomes instantaneous and no heat is lost, and in the Bessemer converter a well-arranged set of tuyeres blowing vertically upwards produces such an intimate admixture of oxygen and carbon as to create a succession of small harmless explosions, and hence fixes a limit to the safe diffusion of these combustible elements.

A converter with a group of seven tuyeres, each having seven separate passages through them, will direct vertically upwards forty-nine separate streams of air through the metal; this air dividing itself into countless thousands of small globules rushes upward, producing a light column of mixed iron and air, while the denser portion of the iron forms descending columns and keeps up a powerful circulation, equalising the temperature and the rate of combustion, while a single nozzle pointing downward, as tried by Kelly, will not diffuse the air throughout the mass, but the air will rise up all around the nozzle and soon melt and destroy it. Air applied in this manner can never set up that amount of circulation and vivid combustion throughout the whole mass which is an absolute necessity if fluid malleable iron is to be produced and cast into ingots, conditions absolutely impossible to arrive at in a shallow open vessel with one tuyere blown downward.

Indeed, Mr. Weeks is constrained to admit that Kelly could not make fluid malleable iron in his apparatus owing to its inherent defects in principle, which Kelly had not scientific knowledge enough to perceive or mechanical skill enough to remedy.

The precise words which Mr. Weeks adopts from Mr. Holley, in this confession of the failure of Kelly to produce fluid malleable iron, are as follows:—"Mr. Bessemer's invention consists in the mechanical means for intimately diffusing the air through the mass of iron to such an extent that the mechanical changes take place with sufficient rapidity to leave the mass fluid after the carbon and silicon have been removed, while the means employed by Kelly were not adequate to carry the process to the same extent." Hence, with his one tuyere blowing downward, Kelly could not, and did not, produce fluid malleable iron; and could not, and did not, make an ingot; and could not, and did not, carry out the Bessemer process, which consists in the production of ingots of cast steel by forcing numerous streams of air upwards through the molten crude or cast iron. This failure of Kelly was the result of his entire ignorance of the essential principle on which the Bessemer process is based, viz., the rapid diffusion of minute fiery bubbles throughout the entire body of the metal under operation.

This abortive attempt of Kelly—if ever made—was by Mr. Weeks' own showing abandoned some years before I read my Cheltenham paper, having never served any useful purpose whatever.

Had Kelly patented his invention, had he read a paper on it before any scientific institution, or had he published an account of it in the public press, it might have been said that a published account of even this most unsuccessful and abortive attempt would have acted on other minds and suggested a more perfect system; but Kelly did not in either of these ways, or in any other way, make known or convey any knowledge to the outer world as to what he was trying to do, and hence his labours have not by the smallest possible increment advanced the general stock of knowledge or influenced to the most infinitesimal extent the progress of steelmaking either in America or elsewhere. All that Mr. Weeks has succeeded in doing is to show that an American citizen, if he ever had in his mind the idea that malleable iron could be produced by currents of air, could yet be so entirely devoid of mechanical skill, so hopelessly ignorant of the physical laws which govern the whole theory on which my invention is based, that, after pottering over his ill-devised schemes for a number of years, he failed hopelessly, and gave it up, having never benefited the world to the smallest possible extent. He never even thought it worth while to patent his invention during all the nine years from 1847 to 1856; but as soon as he found that my invention was agitating the whole iron trade of Great Britain, he woke up and commenced a fierce fight with affidavits in the American Patent-office, after I had already obtained my patent in America, and after all my English patents were published in Blue-books, which at the small cost of 6d. each were open to Kelly's and every one else's inspection; in them they could see every detail of my several inventions. Then it was, we are told, that "Pompey was very like Cæsar," and that there was a wonderful identity between Kelly's invention and mine, but this similarity did not come about by my patenting in America an apparatus with one tuyere blowing downwards.

Any one would have thought that a person in Mr. Weeks' position must have had the honour of his own country more at heart than to drag such a lame story from the obscurity in which, to the honour of America, it had for forty years been buried.

The fact of Kelly obtaining a patent in America after mine, rendered it necessary for all the manufacturers of steel in America to work under both patents, so all the trade knew perfectly well what Kelly's title to be called an invention really was, and with this full knowledge they unanimously joined in always calling it the Bessemer process. The Americans have, with this knowledge before them, elected me an honorary member of the American Society of Mechanical Engineers, and also an honorary member of the American Academy of Arts and Sciences, and in several parts of the United States, where Nature has richly endowed them with those aids to civilisation, coal and iron manufacturing cities have been established to which, by common consent, they have given the name of Bessemer.

Thus we have the rapidly increasing and important city of Bessemer, Gogebec County, Michigan; the city of Bessemer, Alabama, with its mayor and Corporation, its street tramways and electric lighting, and its large manufacturing works, public schools, and numerous churches. There is also the city of Bessemer, Lawrance County, Pennsylvania, the seat of the great Edgar Thompson steel works, the largest in America. There is also the city of Bessemer, Botetourt County, Virginia, and the city of Bessemer, Gaston County, North Carolina.

Nothing could more clearly show the spontaneous recognition of a whole nation of the enormous benefit that the Bessemer process has conferred on the trade and commerce of the United States.

The great wave of excitement produced on the public mind throughout Europe by the announcement of my invention at Cheltenham, soon forced its way across the Atlantic, and created a great sensation among the iron producers of the United States; among other eminent men it attracted the most earnest attention of Mr. A. S. Hewitt, whose high position is fully recognised throughout the United States, and who made the following statement in reply to Sir James Kitson, the honoured President of the Iron and Steel Institute, when Sir James was in America in 1891. Mr. Hewitt said:—"Mr. Bessemer read his celebrated paper describing the process of producing steel without fuel at the Cheltenham meeting of the British Association for the Advancement of Science in the summer of 1856. An imperfect report of this paper was published in the journals of the day, and attracted my notice. The theory announced seemed to be entirely sound, and the apparatus simple and effective. I gave orders at once, without further information than that derived from the published report, to erect an experimental vessel for the purpose of testing the possibility of producing steel direct from the blast furnace. In the same year in which this paper was read, the experiment was tried at the furnace of Cooper and Hewitt at Phillipsburgh in New Jersey, and the result served to show beyond all doubt that the invention of Mr. Bessemer was one which could be successfully reduced to practice."

Now, if Kelly's nine years pottering had created the smallest interest in America, surely a firm like Cooper and Hewitt would have known it and would not have been so anxious to prove the fact as at once to have put a Bessemer converter in operation on an experimental scale.

Mr. A. S. Hewitt, who is a past-president of the American Institute of Mining Engineers, said on the occasion of their meeting at Washington on February 22nd, 1882:—"My firm made an effort within six weeks after the famous Cheltenham paper was read in 1856, to see whether pig iron could be thus converted into steel. It was three or four years after that that Mr. Holley's attention was called to the matter, and he went to Europe and brought back for his friends the control of that patent."

So that Mr. Holley was not in any way interested in this question for some years after Kelly knew all about my several patents, and had plenty of time to shape his invention so as to square with mine, even to the making of a movable converter, which Mr. Weeks says was "an infringement on Bessemer's converter." It is something to get from Mr. Weeks the direct admission that Kelly had made an infringement of my patent. Why is he not more candid?

No sooner were Bessemer steel rails produced in Sheffield than American railway managers began to purchase them, and so important were they deemed to be that thousands of tons were sent to America, realising the almost fabulous price of £20 per ton; and when America began to make their own steel rails, thousands and tens of thousands of tons of Bessemer pig iron were sent from this country to make Bessemer steel with. This Bessemer pig was made by furnace charges invented and dictated by me, all the hematite iron previously made in England entirely failing to make workable steel.

Nor must it be forgotten that the Bessemer converter with its hydraulic moving gear, and the hydraulic casting crane and apparatus, the ingot cranes, the valvular casting ladles, pair of vessels arranged in a semi-circular pit, the conical moulds, and, in fact, the whole plant, outfit, and arrangements of the American steel works, are the patented inventions of Henry Bessemer, although somewhat modified in their mechanical details by the late Mr. A. L. Holley, so as to suit the American practice; but Bessemer's patent machinery is still used, with scarcely a deviation in detail after a period of nearly forty years in every country in Europe where Bessemer steel is made.

The British Patent-office shows all the successive steps in the development of my invention, and with these evidences of its origin and vitality scattered all over Europe and America, it is simply an outrage on the man who has done all this, and to whom America is so deeply indebted for the great extension of her manufactures, her commerce, and her prosperity, and to set up as the original inventor of the Bessemer process a man whose abortive schemes have not added one tittle to the public store of knowledge, or benefited the world or even his own country to the value of a single cent; it is nothing less than an outrage on the common sense of the scientific world. HENRY BESSEMER.

London, March 19th.

NAVAL GUN SIGHTS.

SIR,—In the article you publish in your issue of March 6th, on "Quick-fire Naval Gun Sights," you raise a question of much interest, not only to artillerists, but also to opticians and mechanicians, namely, the possibility of having a gun sight which will be at once a range finder and gun adjuster, or rather, perhaps, one should say a gun sight which will dispense with the need of knowing the actual range. You refer to the proposal to use a telescope the focussing of which would indicate the range of the object focussed. As you further refer in appreciative terms to the work done by Dr. Stroud and myself in the design of range finders, perhaps you will allow me to point out the scientific basis of the method of range finding proposed.

In the first place, I would say that the proposal is not a new one. It has often been suggested and even tried, but it can be shown that it is impossible for it to be successful as a practical range finder for such distances and accuracies as are dealt with in gunnery. If we assume that the eye had no power of accommodation, then a telescope when focussed for an object at one distance will show a well-defined object at any other distance out of focus, that is with a more or less indistinct or hazy outline; the hazy image being in fact practically a multitude of partially superimposed images, one for each point of the objective of the telescope. If, then, the objective be all covered up except two small areas, we shall have two images, and these will be separated by the maximum distance when the uncovered areas are at maximum distance; that is, when these areas are at opposite ends of a diameter of the objective.

The telescope then becomes a range finder with a base length equal to the diameter of the objective. The uncovering of the remainder of the objective only obscures the indication by adding an indefinite number of other images more nearly in coincidence—that is, filling up the space between those farthest removed from each other.

The question then becomes, What accuracy can be obtained with a base length equal to the diameter of the objective of a telescope? A diameter greater than 4in. could hardly be contemplated; let us assume that diameter. Now, as we show in the paper recently read before the Institution of Mechanical Engineers, the attainment of the accuracy aimed at involves, in a range finder with a base of 54in., the measurement of an angle of 1 sec. With a base of 4in., the angle to be indicated or read would be $\frac{1 \times 4}{54}$ sec., *i.e.*, say $\frac{1}{14}$ sec. To observe to such an angle, even assuming that one had separated images as in our range finder, would require a magnifying power of about fourteen times that used by us, *i.e.*, say a power of 400 diameters.

It is needless to say that such a magnifying power is impracticable for the purpose under consideration. A telescope such as we have assumed, magnifying 400 diameters, would give almost no illumination. On the ordinary standard for terrestrial and marine glasses a telescope to magnify 400 diameters would require an objective aperture of at least 20in. diameter to give good illumination, instead of only a small portion of a 4in. circle, as would be available for each image in the case of the telescope assumed. But, further, the two images in a telescope such as we have supposed would not be separated, but would be overlapping, and as we show—more especially in our reply to the discussion on our paper—the accuracy of observation under such circumstances is nothing like so great as with separated images.

Again, the eye, contrary to our assumption, has a great range of accommodation. Cross wires—or as you suggest a diaphragm—would therefore require to be introduced to define the focal plane, and the observation would be an exceedingly difficult one, namely, the observation of the coincidence of the two images—or if the whole objective is uncovered, the absence of haziness at the edges—simultaneously with the image being in focus with the wires. such an observation is practically impossible to make.

There is another aspect of the problem that may be referred to. Take the standard of accuracy to which we work, namely, one per cent. at 3000 yards, and assume that the telescope has an objective of 7ft. focal length—a greater length could hardly be contemplated. Now the change of focus for a change of distance from 3000 yards to 3030 yards in a telescope having an objective of 84in. focal length is only something like $\frac{1}{1500}$in. Even supposing, then, that the eye could detect this change of focus, the mechanism actuating the focussing motion of the telescope in conformity with the elevation of the gun would require to work correctly to at least $\frac{1}{1500}$in.

As a matter of fact, a single observer range finder, having a base at right angles to the line of sight, may be regarded as a focussing instrument on the lines you suggest. Thus in our range-finder we have the equivalent of a lens of 54in. diameter—with all the useless part of the lens removed—together with what is virtually an accurate means for measuring the position of the focal place, that is the plane where the two images formed by the extreme pencils of light are in coincidence.

It is difficult enough to construct a range-finder with a base of 50in. to 60in. that will measure a distance of 3000 yards within one per cent., and one may be justified in saying that the construction of a range-finder of a few inches base, for such accuracies as are required for gunnery purposes, is impossible.

The University, Glasgow, March 16th. ARCHIBALD BARR.

ENGINE POWER IN PADDLE STEAMERS.

SIR,—The very interesting particulars which you give in your last impression concerning the new Flushing steamers have stimulated in my mind a desire for more. The speed of these vessels is no doubt high, but it seems to me the power required to obtain it is also out of all proportion high. I am led, therefore, to ask for some further information from any of your readers competent to give it, for I take it for granted that on so important a subject you have given all that was given to you. This question of high-speed paddle steamers for continental and short sea routes is of very great interest, as boats of this class are greatly preferred for passenger traffic to screw steamers, which are, as a rule, dreadfully liable to vibration, as, for example, the exceedingly fast twin-screw boat, Jersey, running from Southampton.

You do not give the displacement of the Flushing boats, but it cannot well be more than 1800 tons. Yet not less than 9000-horse power is required to get a speed of 21 knots in the Clyde; not, be it observed, in shallow water, but in deep.

Contrast this with the performance of the Holyhead and Kingstown mail boat, the Ireland, built in 1885, length, 380ft.; beam, 38ft.; tonnage, 2590; indicated horse-power, 6000. The Ireland's speed was 20 knots. I myself saw on one trip 21 knots registered by the patent log. Here we have a very large wheel making few revolutions comparatively, while in the Dutch boat we have small wheels running at a high speed. Only one conclusion can be drawn.

If any one can explain why the machinery of the Flushing boats is so inefficient by comparison with that of the Ireland, or can show that the inefficiency exists only in appearance, and not in fact, I am sure that many of your readers would be interested.

The Ostend boats require considerable power to drive them, but anyone who has stood at the stern of one of them, and seen what takes place when the boats are nearing Ostend at low water, will get a lesson in drag not to be easily forgotten. Acres of muddy broken water seem to follow the ship.

I will not unduly extend the length of this letter, but conclude by asking whether 9000-horse power applied to twin screws would have been needed to give each of the Dutch boats her 21 knots?

Fenchurch-street, March 19th. SUPERINTENDING ENGINEER.

SIR,—I read with great interest your excellent description of the machinery and the accommodation of the three new Flushing steamers, which appeared in your issue of Friday last; but I must confess that I was surprised at the enormous power of 9000 indicated horse-power being required to drive them 21 knots. Surely this is incorrect, as I have before me the particulars of a steamer of practically the same dimensions, which in regular running is driven at the same speed by 5000 indicated horse-power.

If 9000 indicated horse-power be the correct power, and not a clerical error, then it would be interesting to know the displacement, the mean draught, the length and breadth of floats, the depth of the wheel race, and the height of the centre of the shaft above the water-line of these vessels when steaming 21 knots, because the question of the efficiency of a paddle-wheel engine running at 63 revolutions per minute, compared with that of a similar engine running at 40, may or may not be involved in it.

Birkenhead, March 17th. R. B. S.

MESSRS. JAMES WATT AND CO.

SIR,—As another of the former staff of Messrs. James Watt and Co., and by no means "a disappointed man," I beg leave to refer to the letter signed "Soho" in your last issue, which I cannot let pass, conveying as it does a veiled insinuation against the members of the staff of the late firm.

The letter of "One of the Staff" was merely a correction of the inaccurate statement that the old hands were at their posts, and hardly merited the tone adopted by "Soho." Of course, Messrs. Avery are quite at liberty to engage whomsoever they please; but I may remind "Soho" that many, if not all, Messrs. Watt and Co.'s old officials have found as good, and even better, situations with other firms of equal eminence, who are quite competent to judge of their capabilities.

Moreover, "Soho" should know that the staff cannot be held answerable for the misfortunes of the old firm, nor, I venture to say, do Messrs. Avery know much of the individual merits of the hands they have lost; but this I will say that, if they do not replace them by other engineers, they can never hope to make engineering as successful as scale-making. More I feel the position I held with the late firm forbids me to say, but while regretting the evil times that have befallen the historic house, I beg to assure you, on behalf of my late colleagues—as one who has served the firm for nineteen years—at Soho and in London, that no more trustworthy body of men ever found themselves on the deck of a sinking ship. All the same, Sir, most of us have found the shore.

T. H. A. BIDDLE.

146, Grange Park-road, Leyton, March 17th.

THREE-CYLINDER LOCOMOTIVES.

SIR,—Referring to your article on three-cylinder locomotives in the current issue of THE ENGINEER, may I point out that the cylinder arrangement you advocate has been published by me on several occasions during the past few years, both here and in America and India? To mention one case only, it may be found in my discussion on Mr. Edgar Worthington's paper on locomotives read before the Institution of Civil Engineers—vol. xcvi., Part II.

The arrangement is illustrated in the volumes of the Institution. The one thing difficult to understand is how any other three-cylinder design could possibly be contemplated in face of the increased complication of different sizes, &c. With all the cylinders of one diameter, manufacture can be simplified, for there need be but one pattern of piston, &c., and at the same time every ratio of cylinder capacity can be secured by suitable choice of the inside crank. Nor can a pressure of 160 lb. be looked on as excessive for even a 23in. cylinder. Both mechanically and thermally the inside cylinder ought to be the high-pressure one in a compound locomotive. Then with two low-pressure cylinders there would be less trouble with the exhaust than with the huge low-pressure cylinder of the Webb compound. And, again, with three equal cylinders boiler steam could be used in all three when taking a heavy load or a steep bank. W. H. BOOTH.

36, Rosendale-road, East Dulwich,
March 14th.

SIR,—In your issue of the 13th inst. you write a leader on the above subject, and you describe what I may call my system of compounding locomotives. I have, perhaps, considered the locomotive question as much as anyone, and concluded long ago that the two-cylinder compound system was not the best for working passenger traffic in this country. The enclosed pamphlet clearly describes and illustrates my methods. W. M. SMITH.

16, Otterburn-terrace, Jesmond, Newcastle-on-Tyne,
March 16th.

SIR,—Referring to your article in last week's ENGINEER on triple cylinder locomotives, it would perhaps interest you to know that some time since I made a drawing of a locomotive, ordinary English type, in which I got inside cylinders 22in. by 30in., and an ordinary locomotive type boiler of ample power. It is on the lines laid down in your article. I shall be pleased to send you a tracing if you wish, and you could publish it if you think it of sufficient interest to your readers. ERNEST E. BAGULEY.

Stafford, March 18th.

[We shall be glad to see the tracing.—ED. E.]

SANDY PIG IRON.

SIR,—Does the varying quantity of sand that sticks on the undersides of pig iron run from a blast furnace make any difference in the quality of the product when again melted in the founders' cupola or softened in the puddling furnace? Or is the clinging sand entirely fluxed and passed away among the slag, or does part of it, as silicon, seize upon the iron and become incorporated into the nature of it, in either puddling furnace or cupola?

I observe that imported Swedish cast iron for the purpose of making the higher grades of steel is free from sand sticking on the underside. On what material is the Swedish iron run from the blast furnaces?

It seems to me that a change is wanted in the ancient practice of running out the contents of a blast furnace into "sow and pig," whereby it will avoid the carrying away any sand sticking to it.

Does not the varying quantity of sand sticking to pig iron account for the differences of quality obtained from the same mixtures and brands of iron? W. B.

March 18th.

FAST TIME IN FRANCE.

SIR,—Possibly the following details of a run on the Northern of France Railway on Thursday last may interest some of your readers. The afternoon boat express from Calais to Paris ran from Calais-Town—to Amiens in 111 minutes, and from Amiens to Paris in 103 minutes, the distances being, I believe, 102 and just under 82 miles. The speeds were 55 miles per hour for the first run and 47 miles per hour for the second, this last including a long dead slow into the Gare du Nord. The train consisted of about fourteen coaches, weighing probably 140 tons. The engine from Calais to Amiens was one of the new four-cylinder compounds, No. 2146, and from Amiens to Paris, No. 2139 of the same class.

Paris, March 15th. R. COLLIER.

SLIDE VALVE FRICTION.

SIR,—The question of slide valve friction is rather a difficult problem to tackle. Mr. E. J. M. Davies and "C. D." both show the valve as being new and not worn. I send a sketch of what the valve wears to; perhaps some one may go into the question of the friction of a valve as shown in Fig. 1. Immediately the valve opens to port A, the pressure is relieved on more than half, and is on B only. Fig. 2 shows how a straight-edge should be held on the face of the valve to find out the wear. The sketch is purposely exaggerated; the distance from *a* to *b* in Fig. 2 may be anything from $\frac{1}{32}$in. to $\frac{3}{16}$in. Why slide valves are tolerated when piston valves can overcome the defect, it is hard to conceive. However, this is only one of the very many grave defects of our modern locomotive.

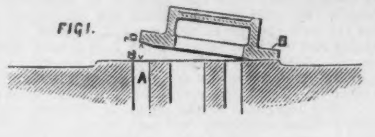

FIG 2.

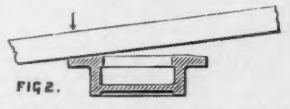

JOHN RIEIKIE,
District Locomotive Superintendent
Indian State Railways.

Lahore, February 26th.

LINK MOVEMENT ENGINE.

SIR,—With reference to Mr. Chapman's ingenious arrangement for producing circular motion from two rectilinear motions at right angles to each other, you point out that it is not possible to dispense with guides because the pressure on the piston varies. I would like to point out that when either piston is at the end of its stroke and the other piston at mid-stroke, then the transverse pressure on the piston-rod of the former is equal to the total piston pressure on the latter, and hence guides would appear to be necessary. The peculiarity that the piston stroke is four times the radius of the crank may be of use in a gas engine. W. H. T.

March 18th.

---

x RAYS.

SIR,—It may interest your readers to know that the authorities of Faraday House, Charing Cross-road, have placed in one of the private rooms the necessary apparatus for photographing by means of *x* rays. This has been done at the suggestion of certain prominent members of the medical profession, and already a large number of negatives have been produced. The apparatus is, of course, manipulated by the staff of the institution, but it is desirable that patients should be accompanied by the medical gentleman who is attending them. H. H. P. POWLES,
Engineer.

Faraday House, Charing Cross-road,
London, March 18th.

SWEEP CUTTING BAND SAWS.

SIR,—Referring to the descriptive illustration of a band saw for sweep and bevel work, appearing in your last issue, may I be allowed to state that this system of sawing wood was invented and patented by C. R. Western and T. Hamilton, London, in 1873, Pat. No. 3203? Several machines were constructed under this patent by Messrs. Western and Co., Lambeth, notably one for Samuda's shipyard, which was working up to a short time prior to the late sale there. *Palmam qui meruit ferat.*

W. SAMUEL WORSSAM.

28, Victoria-mansion, Westminster, S.W.,
March 17th.

THE JANDUS ARC LAMP.—We are requested to state that a company has been formed specially to deal with the manufacture of this lamp, called the Jandus Arc Lamp Electric Company, and the sole sale of this lamp for the United Kingdom is in the hands of Messrs. Drake and Gorham, Victoria-street, Westminster.

THE CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—At the ordinary meeting held on Thursday, March 12th, a paper was read by Mr. H. Coward, C.E., on "The Mechanical Handling of Goods at Riverside Premises." The paper described various old-fashioned means of raising, lowering, and conveying goods from and into ships, barges, and warehouses, and traced the gradual improvement that has taken place in the mechanical means of handling goods up to the present time. The author pointed out some of the troubles met with by those who have to deal with the apparatus that is used, and concluded by describing the Temperley transporter, an ingenious apparatus that is now being very largely used, although but recently introduced to the notice of shippers and wharfingers. Some excellent models were on view. A discussion of an interesting character took place at the conclusion of the paper, among those who took part therein being S. à Court, C. T. Walrond, E. H. G. Brewster, W. R. Hay, J. N. Cooper, W. C. Penn, and P. A. Creeke.

THE INCORPORATED ASSOCIATION OF MUNICIPAL AND COUNTY ENGINEERS.—The following programme of the Midland Counties District Meeting, to be held at King's Heath, near Birmingham, has just been issued:—On Saturday, 28th March, 1896 at 12.15, the members will assemble at the Institute, King's Heath, where the chairman and members of the Rural District Council will receive them. Election of district secretary. 12.30: Paper descriptive of fourteen years' work in a Midland suburb, by Mr. Robert Godfrey, A.M.I.C.E., engineer and surveyor to the Rural District Council; discussion. 1.30: Light refreshments, kindly provided by County Councillor T. R. Bayliss, J.P., A.M.I.C.E., chairman of the Rural District Council. 2.0: Drive to Highbury, the residence of the Right Hon. Joseph Chamberlain, M.P., Secretary of State for the Colonies, who has kindly given permission for the members to visit the grounds and orchid houses. 2.30: Drive to Bournbrook, to inspect the generating station of the electric tram cars, belonging to the Birmingham Central Tramway Company, where the members will be received by Mr. Alfred Dickinson, A.M.I.C.E., the engineer. 3.0: By permission of Messrs. Aveling and Porter, the manufacturers, and Mr. Morrison, the inventor, Morrison's road scarifier will be exhibited at work. 3.30: Drive to Lifford Sewage Works, where the bacillite process of sewage treatment is in operation; fare for the drive, 2s. 6d. per member. 5.0: Arrive at King's Heath, where a cold collation will be provided by the Bacillite Syndicate. Special arrangements will be made to enable members to be at New-street in time for the evening trains North and South.

BRITISH PIG IRON TRADE ASSOCIATION AND FOREIGN COMPETITION.

THE South Staffordshire Institute of Iron and Steel Works Managers discussed at Dudley on Saturday the "Report upon Foreign Competition in the Iron Trade," which was issued some little time back by the delegates which went to Germany and Belgium, under the auspices of the British Association. An account of the document appeared in THE ENGINEER at the time of its publication. The chair was occupied by Mr. W. B. Rubery, of H. P. Parkes and Co., Tipton-green Chain Works, Tipton, as President of the Institute, and there was a good attendance. The secretary, Mr. W. H. Carder, read the principal portions of the Report. Among those present were the Chairman of the Delegation, Col. James Patchett, Managing Director of the Shropshire Iron Company, Wellington, Salop; and also Mr. W. H. D. Gladstone, of Messrs. John Lysaght, galvanised iron manufacturers, Wolverhampton, Bristol, and London; both of whom had represented on the Commission the employers of the Midland Wages Board.

The following other members of the Delegation sent letters of apology:—Employers' delegates—Mr. W. Thackray, jun., managing director of Messrs. Samuel Tyzack and Co., of Sunderland, member of the Board of the British Iron Trade Association, who represented on the Commission the North of England Iron and Steel Manufacturers' Association; Mr. C. Parnaby, manager of the mill department of the Consett Iron Company's works, representing the Board of Conciliation and Arbitration for the Manufactured Iron and Steel Trade of the North of England; Mr. J. R. Winpenny, Middlesbrough, employers' secretary to the last-mentioned Board, representing that body; and Mr. J. Stephen Jeans, London, secretary to the British Iron Trade Association. Communications were also received from four of the workmen's delegates, namely, Mr. Edward Trow, operators' secretary of the North of England Iron and Steel Conciliation Board, and general secretary of the Associated Iron and Steel Workers of Great Britain, who was vice-chairman of the Commission; Mr. James Cox, vice-chairman of the North of England Iron and Steel Conciliation Board, and assistant-secretary to the Associated Iron and Steel Workers; Mr. W. Ancott, operative secretary of the Midland Wages Board and president of the Associated Iron and Steel Workers; and Mr. P. Walls, of Workington, general secretary of the National Federation of Blast Furnacemen, and agent for the Cumberland and Lancashire district. Mr. Cox, in his letter, called attention to the second paragraph of the memorandum, with which the British Iron Trade Association had prefaced the report. That memorandum was signed for the Association by three of its chief members; and the paragraph in question stated:—"Great difficulty was found in agreeing upon the deductions to be drawn from the evidence obtained, and the report is therefore necessarily somewhat colourless." This—Mr. Cox continued—was an absolute misrepresentation of the facts, and the substitution of the word "unanimity" for "difficulty" would have more nearly represented the truth. The whole of the employers and operatives composing the delegation had been anxious that whatever the report might be, it should be in strict accord with facts as they saw and found them, and that alone was the standard of measurement to which any suggestion was subjected from whichever side it emanated. However opinions might vary as to the colour of the report, it was one founded on personal investigation by practical men—employers and employed—who determined to keep it as far as possible within the limits of their own observations and investigations, uninfluenced by outsiders, without incorporating into it the "colouring" of official German and Belgian publications, whose figures and facts they had no means of verifying. Mr. Trow in his letter confirmed Mr. Cox's assertions as to unanimity. Mr. F. Scarf, of the Bromford Ironworks, West Bromwich, held by letter that the cost of carriage occupied a foremost place in any proper consideration of the facts underlying the successful competition of German and Belgian works. The task of comparison was made more easy by the fact that the iron producing districts of those two countries were situated in what was practically an identical position with South Staffordshire, so far as the distance from a seaport was concerned. The report showed very clearly that with an equal mileage, Midland works were handicapped to something like the extent of 7s. 6d. per ton. A reduction of railway rates might do something towards removing the difficulty, but it was evident that British railway directors, handicapped as they were by immense capital charges, were, even if willing, quite unable to make the sweeping reductions in rates which would be necessary to produce anything like equality with those to which our foreign competitors were subject. The State purchase of railways, if possible, to say nothing of the doubt of its being beneficial, was too big a question to discuss there. The only other hope was water carriage. The utter failure of the Manchester Ship Canal, at any rate for the present, had discredited enterprises of that nature, and he would be a bold man who would suggest bringing a canal of that magnitude into the Midlands. But a canal capable of carrying barges of 150 tons capacity need not be expensive, and would effect an enormous reduction in the present rates. Between the cost of hauling a barge of 150 tons and one of 25 tons capacity the difference was very trifling; and by such a waterway he believed the cost of carriage to Liverpool could be reduced to 3s. 6d. per ton. In some such direction as that, he was convinced, they must look, if South Staffordshire was to hold its own in the export markets. Mr. Walls, in his letter, pointed out that in the appendix to the report, second day's proceedings, works "B," in Belgium, it was shown that when the delegates asked for the total wages cost of labour on a ton of pig iron the director of those works said it ranged from 1 fr. 85 centimes —1s. 6½d.—to 2 fr. 50 centimes—2s. 1d. But he—Mr. Walls—wished to point out, in order to prevent any misapprehension, that that only meant the work back and front, and did not include anything for blast engine men, locomotive men, boiler men, tippers, pig iron chargers, or any outside labour. Without this knowledge, the figures were calculated unintentionally to mislead.

The Chairman dwelt upon the superiority of the mechanical appliances of the Germans, and upon their improved methods of output; strikes were almost unknown; technical education was superior; and railway rates were lower. He was afraid that in England there was such a thing as an export quality of iron and steel, which was practically another name for the commonest class of material. This was calculated to do England a great deal of harm. The reluctance on the part of manufacturers to give credit to foreigners was also against the extension of our export trade.

Mr. H. M. Punnett—Punnett, Thompson, and Co., ironmasters and galvanised iron manufacturers, Regent Grove Ironworks, the Cape, Birmingham, and Stork Galvanised Ironworks, also of the Cape—said he had been asked to attend on behalf of the Midland Iron and Steel Wages Board, and he should confine his remarks entirely to finished iron and steel, and mainly to sheets. In some of the sheet mills they were rolling with very much less waste than we were accustomed to do in this country, and that was, to his mind, a very important matter, which we ought to consider most carefully in this country. At one of the works they had both soft and hard rolls. It was a habit, he believed, in Staffordshire to have hard rolls for plate mills, but not for sheet works. The American practice in sheets was to have two sets of rolls, so as to break down in one set, and finish in another. A large proportion of the sheets produced in Germany were of very high quality; some of the material produced was more like that usually turned out by a high-class steel tin-plate works. At "H" and "J" works, lattens were being rolled in a loose state. That puzzled him, and he expected it would puzzle some of the members of the Institute. He held that the report was of the greatest value. We must not suppose that other countries were not progressing. America for many years had sent scientific men all over Europe to ascertain what was being done, and England must consider it to be her duty to do the same. It was most important that we should ascertain all information possible. That Commission should be a mere preliminary to further investigations. The Commisson said there was more attention paid to quality in England than in Germany. That was true as regarded low qualities of iron, but not true with respect to the excellent material which the delegates saw at "H" and "J" works. That was basic Siemens-Martin steel, and it was not surpassed in quality by any place in the world. Samples lay in his office at Birmingham. The Commission said, "In the manufacturing departments of the works visited, the production per man did not appear so favourable as in our own industries, taking into consideration the number of men employed relatively to the average results." He thought that was a great mistake. The delegation found that the uniform steadiness of the growth of the iron industry of Germany from year to year, and the inconsiderable backward variations in the production of ores, fuel, iron, and steel, justified the conclusion that the operations of industry were carried on more steadily in that country than in our own. That might, of course, be due to greater steadiness of trade, but might also be due to the more steady-going character of the workmen employed. The delegates were informed that in Germany strikes were almost unknown. It was obvious that the steady course of industry in any country had a tendency to give stability and permanence to its operations, which could not be expected from other conditions. He thought that was a very important point, because one of our greatest difficulties in England was to get a regular steady production at the works. That was one of the things in which England was far behind Belgium, Germany, or Austria. The Commission had expressed the opinion that the success achieved by continental countries in the struggle for commercial supremacy was not so considerable as had sometimes been stated; but from that he must beg to differ. For example, take the imports into India in 1894. Iron from England amounted to 50,600 tons, and iron from Germany to 52,400 tons. Steel from England was 19,150 tons, but steel from Germany reached 28,127 tons. Then, again, the sheet iron exports from Germany to Russia rose from 6073 tons in 1892 to 12,218 tons in 1893, and to 28,026 tons in 1894. He thought that in the English iron trade it would be well if we could adopt the German method of more men and a more equable distribution of wages. America had passed through the same unrest that we were experiencing with regard to hours of labour, and America had adopted the eight hours day, and he should like the general managers of England to see whether they could not find some method by which they could adopt in England a shorter day for the more laborious kinds of work, or a diminution of hours for the individual man and a raising of the number of the total staff. That was a point of most vital importance for the well being of the trade. The eight hours day was doing great things for America. A large roller in America told him the other day that when the men were ill they fell back on the twelve hours principle from the eight hours, so that they never stopped. He—Mr. Punnett—was dead against the habit of the head man paying his own hands. Every man ought to be paid from the office direct. When the schedule of prices was drawn up some time back in the Midland sheet iron trade he was very desirous that they should go back to the old principle of paying every man from the office. It raised the men to the same level as their colleagues, and it gave the employers direct contact with every individual man. When he was a member of the Wages Board Committee who formed the Sheet List he had most of the members against him on that point, but he yet thought that he should see the day in England when that plan was generally adopted. All members of the English iron trade ought to be grateful to the commission for giving them that report. He was convinced that we had yet a great deal to do if British works were to be brought up to the high level of German works.

Mr. Ashton, Past President of the Institute, of Messrs. Noah Hingley and Sons, iron masters and chain and cable manufacturers, of Netherton, near Dudley, said the previous speaker had quoted statistics with reference to the exports of Germany to Russia and India. But he thought what concerned us even more were the imports of Germany to the United Kingdom. The exports of the leading descriptions of iron and steel from Germany to the United Kingdom had increased in quantity between 1892 and 1894 about 58 per cent. They had risen from 77,216 tons in 1892 to 90,764 tons in 1893, and again to 122,190 tons in 1894. The details were as follows for the three years 1892, 1893, and 1894 respectively:—Profile and angle iron, 18,942 tons, 31,299 tons, 41,830 tons; sleepers and fastenings, 1539 tons, 983 tons, 1155 tons; rails, 11,303 tons, 9769 tons, 14,492 tons; bar iron, &c., 4490 tons, 3886 tons, 5785 tons; plates and sheets, 480 tons, 192 tons, nil; wire, 23,200 tons, 28,687 tons, 40,230 tons; galvanised wire, 17,262 tons, 15,948 tons, 18,698 tons; totals: 1892, 77,216 tons; 1893, 90,764 tons; 1894, 122,190 tons. That was a very formidable matter for them to deal with, and the report was valuable as pointing out some of the causes of German supremacy. He did not think the reason could be found in the extra cheapness of German fuel. The average price of fuel in Germany in 1894 was 6·68s. per ton, in Belgium 7s. 5½d., and in the United Kingdom only 6·06s., so that fuel with us was cheaper than with them. Then with regard to ironstone, the ores of Germany cost, on the whole considerably more at the furnace than those used in Lancashire or Northamptonshire. Then, again, pig iron was cheaper in England than on the Continent. Foundry pig in Germany was 47·68s. per ton, and in Belgium 46·10s., against 42·8s. in Scotland, and 35·7s. in Cleveland. Forge pig was 40·77s. in Germany, and 40·1s. in Belgium, as compared with only 36s. in Cleveland. And about the same proportion between the countries existed as regarded basic pig. Then they came to the question of wages, but on this they had no exact data. The body of the report referred them to the appendix, but there they did not find adequate information for making a proper comparison, and the delegates themselves in the report admitted that. He thought it might be taken for granted that wages were lower in Germany, but then the German workmen had compensatory advantages. Theirs was what he might call the paternal system. There was no sharp dividing line between masters and men. Employers and employed formed what he might call a large industrial family. Provision was made for the physical and social enjoyment of the people, for they had their reading rooms, libraries, recreation grounds, hospitals, and so forth, and he thought their advantages in these respects were equivalent to an extra 25 per cent. upon their wages; so that they might take it that continental wages, though apparently lower, were in reality very much on a par with English. But the weak spot in our armour was the matter of railway rates. German and Belgian railway rates were only one-third of what they were in England, so that for every ½d. per mile expended in Germany we had to spend 1½d. In other words, the English manufacturer had to pay 10s. 6d. for railway facilities which his German competitor got for 3s. 6d. The English railway companies would no doubt sacrifice their millions to repel the foe if there was a German military invasion, but nothing could exceed their supineness in face of this commercial invasion. Germany's military *régime* no doubt pressed hardly upon her people, but it re-acted beneficially upon her trade and commerce by causing discipline and steadiness in work. In technical education Germany had the advantage of us at present, but we were rapidly coming up to their level.

Mr. Joseph G. Wright—of Isaac Jenks and Sons, Minerva Steel Works, Wolverhampton—said there was a time, within the memory of some of those present, when South Staffordshire was the chief iron producing district of the kingdom, and, indeed, of the world; but to-day the craft was in danger, and it behoved them to look that peril in the face and try to meet it. He was one of those who had looked to the report to help the British iron trade to meet foreign competition, but he confessed to a large amount of disappointment, and he could not but think that there was a good deal which ought to have been said, but which for some occult reason or other had not been said. One of the necessary considerations was the cost of producing iron in Germany and Belgium as compared with the cost of producing it here, but he did not find the details which the report itself spoke of as being present in the appendix. He thought the information was extremely indefinite as to wages, and he believed it to be absolutely impossible to compile from that report the complete cost of making finished iron. There was an allusion in the memorandum prefacing the report to great difficulty having been experienced in agreeing upon the deductions to be drawn from the facts obtained. Now, if there was difficulty, he thought it would have been well that English ironmasters should have been told what the difficulty was. There ought to have been a proper tabulated statement showing wages in Germany and England respectively. He understood, indeed, that such a statement was in existence, and he could not understand why it had not been published. Mr. Wright then went on to criticise the report in detail. They were informed by the report that at one of the works there were two pairs of rolls, two-high soft, and two sets of hard rolls, three-high. They were 21in. in diameter, and were running at least 110 to 120 per minute. Now when we found that in this country the speed was 40, or generally nearer 30 revolutions per minute, one could not understand how so great a speed as that named could be run. An English roller would stand aghast if you told him to put a bar 1in. thick between rolls running at that speed, and would want to know who was going to be responsible for the machinery. He could not understand how they could put a bar in with the rolls running at such a speed, without shock to the machinery and the jumping up of the rolls against their screws and chucks. Nor was any explanation given of the statement that in some of the mills there was no doubting, but that all the sheets were rolled off loose. How could they finish off lattens in such sizes, as they were said in the report to roll them, without any doubling? Then something was said in the report about the extremely strong machinery which in Germany and Belgium they employed—very much stronger than ours. It had been said that where we had housings for our sheet mills five tons in weight they had theirs weighing twelve tons. That was rather startling, though the speed of the machinery seemed to indicate that it was correct. In a treble mill at one of the works the output was only 10 tons 17 cwt. per week. Much was said about the high finish of those sheets, but he thought there must be some mistake in the output being so small. He hoped that meeting would pass some resolution on the railway rates question and forward it to the Government.

Mr. Moses Millard—also of the Minerva Iron and Steel Works, Wolverhampton—scathingly attacked the report, and thought the praise of the splendid German machinery and methods implied a serious reflection upon English iron and steel works' proprietors and managers. The report did not give any more information than was given by Mr. Thomas Morris, of Workington, thirteen years ago, when he read a paper upon the iron and wire manufacture of Westphalia.

Mr. J. W. Hall, Bilston, welcomed the report, because it showed us how we stood with regard to our competitors. It was too late in the day to retain the old idea that we were the chief manufacturing country in the world. Though an increase in the exports of iron and steel, as shown by the Board of Trade returns, must be considered satisfactory, any increase in output being an advantage, yet an examination of the figures would show how that increase had been obtained—namely, by reducing the price. Thus the average price per ton for January and February, 1893, was £8 4s. 3d.; for the same period of 1894, £8 3s. 1d.; and for the same period of 1895, £7 8s. 2d. Under these circumstances it would be easily understood why the volume of exports for 1895 showed an increase of 29 per cent. and 43 per cent. respectively over the two previous periods. It was evident that we must look to reduction of price alongside of maintenance of quality, as our only hope of success in neutral markets. We could no longer rely upon brands, trade marks, or other exploded devices.

Colonel Patchett replied on the debate as chairman of the Commission. Some of the previous speakers seemed to be labouring under a mistake as to what the object of the Commission was. The delegation arose out of a document issued by Mr. William Jacks and Mr. Stephen Jeans, who made statements that the low wages paid in Germany was the whole cause for the continental success in competition. The leaders of the British operatives, having this constantly flaunted in their faces, decided on their part to send men to Germany and Belgium to ascertain the facts for themselves. Then invitations were issued to the employers, and they consented to accompany them. He—Colonel Patchett—had nothing to do with the British Iron Trade Association, and the memorandum of that association prefixed to the report had neither the consent nor the approval of the delegation, and ought not to have been put there. The delegates did not hold themselves responsible for that memorandum which those three gentlemen had signed—namely, Sir Alfred Hickman, president; Mr. William Jacks, past president; and Sir B. Hingley, past president. But the body of the report, and also the appendix, was the truth, the whole truth, and nothing but the truth, for every word had been revised and approved by the different works themselves. Colonel Patchett proceeded to dwell upon the difficulties of the undertaking, on the absence of any programme, and the necessity for making arrangements day by day. They were well received, because they went openly and honestly to every place and told them their object plainly, which was to inquire into the relationship between masters and men. Some of the speakers seemed to have expected them to have come back laden with details about sheet iron rolling, but their object was not to go to Germany to take drawings of sheet mills. Indeed, they went out not for the sheet trade nor for any other trade in particular, but for the iron trade as a whole. He indignantly refuted the allegation that there was anything concealed. Everything was open and straightforward. As to the 110 or 120 revolutions per minute of the rolling mill, he saw it with his own eyes, and he was as astonished as anybody else, but it was a fact. Steamship rates were one cause of German superiority. The Peninsular and Oriental Steamship Company was heavily subsidised by the British Government, and yet, whilst charging only 10s. per ton for shipment from Antwerp to Bombay or Calcutta *viâ* London, it—until recently—charged 15s. 9d. to British manufacturers from either London or Liverpool. This difference of 5s. 9d. per ton above the rates paid by continental manufacturers was accountable for a good deal of our difficulty. As to railway rates, that was a difficult question. No doubt we were handicapped in that respect also, but railways were one of the best investments the public had, and the interests of the public were practically bound up in the interests of the railways. It would be a serious disturbance to commercial and general conditions to alter the railway system, whose capital was, he believed, in England about £1,000,000,000 sterling. Some people advocated the State taking over the railways, but they must be prepared if they did this to pass through the same experience as in Germany, where no dividends were paid, and where the people were practically taxed to start the railways and taxed to maintain them. German railways were carried on by military high-handedness, but ours at present were regulated by the free-handed dealings of commerce. Nothing would have been simpler than to have made a comparative table of wages in England and Germany; but nothing would have been more misleading, for such a table could not have given the conditions under which those wages were paid. In puddling, for instance, the thorough way in which that operation was conducted in England was four or five times as laborious as in Germany, so that a comparative statement of puddlers' wages would have been most misleading and unfair. The Commission was, he thought, unique, because it was the first time masters and men had gone together from this country in a friendly spirit to find out what was right and just between them; and he could say that if the delegates had not met the desires of every critic, they had at any rate, tried to the best of their ability to do what they could. The delegates compared notes every night after travelling 200 or 300 miles in the day time, and several times his morning bath, when it was brought in, found him still busy as he had been all night, making records or completing arrangements for next day. It was evidence of the good feeling that had been promoted and cemented between the two countries that Albert Hoesch, of the great Hoesch Company, Westphalia, should have written so friendly a letter about the delegation as that which was printed at the end of the report.

Mr. W. H. D. Gladstone—John Lysaght, Wolverhampton, Bristol, and London—who was another member of the Commission, corroborated Col. Patchett's opinions.

The meeting, before concluding, passed a resolution of thanks to the two last-named gentlemen for attending.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

On 'Change in Birmingham to-day—Thursday—there was, as usual towards the close of a quarter, a rather quiet tone. A few inquiries were made for quotations for next quarter, but more will doubtless be done in this respect a little later on. Prices were practically unchanged on those given last week, both in pig and finished iron.

What is believed to be the largest order ever given at one time to any company in England for carburetted water-gas plant, has lately been entrusted by the Birmingham Corporation to the Economical Gas Apparatus Construction Company. It is of the capacity of 4,000,000 cubic feet daily. It is of the "Lowe" type, embodying the improvements of Merrifield, Westcott, and Pearson. There is to be an installation both at the Windsor-street and the Saltley Works, in each case there is to be two complete sets of generating and carburetting apparatus, with ample condensing, washing, and scrubbing power; also "blowers," exhausters, engines and pumps, oil heaters, &c., each item being in duplicate, and each equal to the working of both sets of generators. At each works the capacity of the plant is to be about 2,000,000 cubic feet of gas per day, making 4,000,000 in all, or about one-sixth of the present make per day. It is, however, in contemplation to add to the water-gas plant, if satisfactory, and as the demand continues to grow, until it is equal to a third of the make. The capital outlay upon the two installations, including buildings and oil tanks, now ordered, will be about £60,000, as compared, it is said, with at least £130,000, which would be required upon the most economical lines for coal-gas plant of corresponding capacity.

The Patent Shaft and Axle-tree Company, at its annual meeting on the 13th inst., was not able to look back upon a very good year, the net profit on the year's trading being only £826, though in addition to this there was a balance of £3808 brought forward from last year. During the greater part of the financial year the best customers, the railway wagon companies, have been quiet, and have given out very few orders. During the last three months of the financial year, however, the Patent Shaft Company has been tolerably busy in supplying steel of special quality for tube making. It has also done some good work during the year, which ought to bear fruit later on. It has also abandoned old machinery in favour of machinery that is modern and more useful. Improvements have also been made in other departments. The wheel department will soon reach a point of efficiency it has never attained before, and the company is laying down a press of about 2000 tons power, from which they expect a great deal.

The well-known gas engineering concern, John Wright and Company, of Birmingham, have had an excellent year. They have made a net profit of £14,324, which, with the amount brought forward, gives a total of £17,388. They have, therefore, been able to recommend a dividend at the rate of 6 per cent. per annum on the preference shares; 10 per cent. on the ordinary shares; and have placed £6000 to the reserve fund, thus raising it to £25,000, whilst a little over £3000 is carried forward. It was stated that the large corporations of the kingdom were buying increasing quantities of gas-consuming apparatus because they were endeavouring to dispose of, for heating and other purposes, the gas which the electric light rendered unnecessary for illumination.

The competition of English and continental boilers for British Admiralty use was one of the topics dealt with at a recent meeting of the Birmingham Municipal Technical School Engineering Society, when a paper on "Steam Boilers" was read by Mr. Thomas Nichols. An interesting account was given of the author's experience in the United States and in the Argentine Republic with water-tube boilers. As such boilers had been more extensively used on the Continent and in America than in England, foreign engineers had naturally obtained greater experience in their design and construction, hence it was scarcely surprising that the Admiralty in searching for a compact boiler of light weight and great steaming power should have been led to try the Belleville boiler, of French origin. Her Majesty's first-class cruisers Powerful and Terrible are each fitted with Belleville boilers, said to be capable of producing sufficient steam to develope 25,000-horse power, and under the present naval programme a large number of such boilers will, it is thought, be adopted. In the author's opinion, however, Messrs. Yarrow and other English makers of water-tube boilers have scarcely received just treatment at the hands of the English Admiralty. Yarrow water-tube boilers are largely employed by foreign navies, but the feeling is general in engineering circles that the question of first cost frequently prevents our own Admiralty from adopting such a course in the equipment of the machinery of our warships as would ultimately be the best and the cheapest.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—The quiet tone I have previously reported in the iron market here continues, and it seems not unlikely that there may be a lull as regards further buying of any moment until after the holidays. The general position of trade, however, continues good, the principal iron-using branches of industry being all well engaged, and with new work coming forward freely amongst engineers, the prospects of the future are unsatisfactory. As, however, I have already pointed out, both consumers and merchants are mostly well covered for some time forward—in many cases, in fact, considerably over-bought—and are only partially taking their deliveries on account of contracts. For pig iron there has been only a small inquiry on the Manchester Iron Exchange during the past week, and although makers' prices are without quotable change, iron held in second-hands has been offered at lower prices, and the position of makers is not quite so strong as it was a week or so back. Local pig iron makers remain firm at recent quoted rates, but district brands have lost the slight advance which makers were getting a few weeks back, and in outside brands there is under-selling. Delivered Manchester, 42s. for forge to 44s. for foundry are now the full prices obtainable for Lincolnshire; 46s. 6d. to 47s. for good foundry Middlesbrough; with Eglinton about 49s. 6d. to 50s. net prompt cash, delivered Dock Quays, Manchester.

In finished iron a moderate business comes forward which keeps forges fully going, but Lancashire bars can still be bought at £5 10s. to £5 12s. 6d., with sheets remaining at £7 10s. to £7 12s. 6d., and hoops £6 2s. 6d. for random to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

Nut and bolt makers report a good demand generally, but any materially better prices difficult to get.

In the steel trade the tone is generally steady, and for hematites makers do not quote under 57s. 6d. to 58s. 6d., less 2½ delivered Manchester, but merchants in some cases are sellers at 6d. less. For steel boiler plates the general quotation is £6 10s. delivered here, with, however, only a small business reported at this figure.

In the metal market the further upward tendency in raw material has brought forward a brisk demand for all descriptions of manufactured goods in the anticipation of another advance in list rates, and there has been a general anxiety to cover on the part of buyers who had been holding back. During the week prices for brass and copper wire and sheet brass have been put up ¼d. per pound, and with a probability of a similar advance upon tubes there has been quite a push of orders upon this class of goods during the past few days. Delivered Manchester district, list rates are now as under:—Solid drawn brass boiler tubes, 6½d.; solid drawn brass surface condenser tubes, 8d.; solid drawn copper tubes, 7¾d.; brazed copper gas and steam tubes, 7½d.; brazed brass gas tube, 7¼d.; brazed brass machine tube, 7d.; brass wire, 6d.; copper wire, 7¼d.; rolled brass, 6d.; yellow metal condenser plates, 5½d. per lb.

The Indian Midland Railways have placed with the Vulcan Foundry Company, of Newton-le-Willows, an order for fourteen heavy goods engines with tenders, of a similar type to those which the company has previously supplied.

All descriptions of round coal continue in very slow demand, with, if anything, a lessened inquiry for the better qualities, and colliery owners find it difficult to keep their pits running more than four days per week. The increased activity in the iron and engineering trades has no appreciable effect as regards the commoner qualities of round coal for steam and forge purposes, supplies of which continue largely in excess of requirements, and prices are so extremely low that colliery owners are in various ways restricting their output as much as possible owing to the altogether unremunerative character of this branch of trade. For ordinary steam and forge coals 6s. remains about the average figure, at the pit mouth, for inland sales, but shipping orders are competed for at exceedingly low-cut figures, 5s. to 5s. 3d. at the pit mouth being not at all uncommon prices for inferior bunker coal, and 6s. 9d. to 7s. 3d. about average figures for ordinary steam coals delivered ports on the Mersey. Engine classes of fuel are showing a decided hardening tendency, especially the better descriptions of slack, and although it is difficult to get any appreciably higher prices, colliery proprietors are declining to contract forward except at some advance upon present rates. At the pit mouth better qualities of slack average 4s. 6d., with 5s. quoted for some special sorts; commoner qualities range from 2s. 9d. up to 3s. 6d. per ton.

Barrow.—The hematite pig iron trade is steady, and a good business is doing in Bessemer qualities on local, home, and foreign account. Makers, generally speaking, are well sold forward, and only deal in forward sales. Holders of stocks are very firm. An increase is noted of 610 tons in warrant stocks, which now stand at 302,029 tons. Prices are firm at 48s. 9½d. net cash sellers, 48s. 9d. buyers. Makers quote 49s. 6d. to 50s. 6d. for mixed Bessemer Nos., net, f.o.b. There are 39 furnaces in blast, as compared with 26 in the corresponding week of last year.

Iron ore is in steady demand, and good orders are being placed, but prices are unchanged, and ordinary sorts are quoted at 10s. per ton net at mines, with best descriptions at 12s. 6d.

Steel makers are very busy on rails, plates, billets, hoops, and castings, and for all these classes there is a brisk demand, with good and steady prices.

Shipbuilders and marine engineers do not report any new orders. The orders for third-class cruisers have this time passed Barrow makers. There is, however, much work already in hand, and that is being pushed forward very rapidly.

The coal and coke trades are much busier.

Lord Harris has accepted the post of chairman of the Naval Construction and Armaments Company, held till recently by the Duke of Devonshire, who felt it necessary to resign the position in view of his appointment as Lord President of the Council in the present Government. His Grace felt it necessary that his official connection with the Barrow company should cease, because of the great amount of work done in recent years for the Admiralty.

Shipping returns show export of pig iron from West Coast ports during last week amounting to 5865 tons, and 9375 tons of steel, as compared with 9015 tons of pig iron and 14,870 tons of steel in the corresponding week of last year, a decrease of 3150 tons of pig iron, and 5495 tons of steel. The total shipments this year represent 64,368 tons of pig iron, and 87,436 tons of steel, as compared with 56,689 tons of pig iron and 83,878 tons of steel in the corresponding period of last year, an increase of 7679 tons of pig iron, and 3585 tons of steel. Freights are still low.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

IN the South Yorkshire coal district no change worth mentioning has taken place. Pits are working very irregularly. Many of the larger collieries can give their men five days a-week; while, on the other hand, three days' work is all that is being afforded in the smaller concerns. Competition is excessively keen, and gets more so every week. Many pits, which are compelled to bring to bank house coal along with hard coal—the latter being chiefly in request at present—are placing the former qualities on the market at lower values. A few minor differences have now happily been settled, and with the exception of a single colliery which has been troubled with water, business has been and is now progressing very steadily, except in household sorts, which is in poor request owing to the extremely mild weather, broken only now and then by a few hours' cold. In London merchants find extreme difficulty in disposing of the weights they have contracted for, and sales are very irregular. Agents wishing to clear stocks are reported as having to sell at a very low figure. Seaborne fuel has fallen in price since last report. Of Yorkshire coal, best Silkstone averages from 8s. to 9s. 6d. per ton; Barnsley house, 7s. 6d. to 8s. 6d. per ton; Silkstone, ordinary, and Flockton, 6s. 9d. per ton; with thin seam about 6s. per ton. Steam coal is in moderate request, considering the season of the year. The amount sent to the Humber ports is about an average, the local pits taking the bulk of the business.

The demand from the home markets is about the same as usual, with prices well maintained. Quotations are as follows:—Barnsley hards, 6s. 6d. to 7s. per ton; seconds, 6s. per ton. Trade in gas coal is not so brisk as when last reported, although prices have not fallen at all. There is a steady demand all round for manufacturing fuel; notwithstanding this, values remain very much the same as when last reported, owing to the large production. Quotations are as follows:—Small nuts, 4s. 6d. to 5s. 6d. per ton; screened slack makes 3s. 6d.; with pit slack, 2s. 6d.; and smudge, 1s. per ton. An increased tonnage of slack is being forwarded to both North Lincolnshire and Northamptonshire, and an improvement in prices has taken place, 8s. to 10s. per ton being the values ruling.

The heavy trades of the city continue to steadily improve. Both Bessemer and Siemens-Martin steels are in excellent demand, and furnaces are well employed. Billets and slabs are booked in large quantities at from £5 12s. 6d. to £6 per ton, while the quotations for the latter quality range from £6 2s. 6d. to as much as £10 10s. per ton. This figure is for the highest grades, and there is a very moderate demand for this class of steel. Manufacturers are loth to order either Bessemer or Siemens far ahead at the prices now ruling. Swedish Bessemer is also well inquired after by continental and American as well as English buyers, and it is rumoured that one or two Swedish firms have offered to buy back stocks at prices largely in advance of those paid for the material. Crucible steel makers report a good business, notwithstanding the keen competition of more rapidly produced steels. A very excellent trade is at present being transacted in self-hardening and other high-class steels. The rolling mills are fully employed, and many of them are working full time.

During the week an improvement has taken place in the price of railway material. It will not be far from correct to say that nearly every class of railway material is £1 higher than the quotations ruling six months ago. The large establishments are better off for work than at any time during the last six or seven years. One branch of this business, however, has not advanced in sympathy with the other departments—that of wagon building. Complaints are freely heard from wagon builders that their business has not improved as was expected. Much more could be produced than is at present being done. Many of the larger firms engaged in making nuts, bolts, &c., have been endeavouring to obtain an improvement in prices, but with little success. Reports as to the state of the iron market are very encouraging, and in many instances better prices have been obtained.

The lighter trades have not advanced in sympathy with the heavy industries. The cutlery branch is in a puzzling condition. Some houses are very poorly off for work, while others cannot execute orders fast enough. Best table and pocket cutlery is selling in large quantities in the home market. A better business is also doing in the cheaper qualities. No improvement has taken place as yet in the American market, although an increased business is reported with both South Africa and Australia. The rupture with Germany has had the effect of many orders in the cheaper classes of cutlery coming to this country, instead of as before to the Fatherland. Celluloid is to a great extent superseding ivory in the Indian, Australian, and South African markets. It is claimed for this material that it stands heat and dryness better than the genuine article. It is being produced in black and other colours, and its uses seem to be unlimited. Xylonite is also in better request, and a better demand has set in for bone and other cheaper qualities of material of hafting. The file trade is in a good condition. Some little ill-feeling is at present existing between the masters and the men regarding wages. Should trade go on improving as at present, the employers will no doubt do something liberal for their workpeople in this matter.

Two important local companies have published their annual reports this week—Messrs. Charles Cammell and Co., Cyclops Steel and Ironworks, Sheffield, Grimesthorpe, Penistone, and Workington; and Messrs. Wm. Jessop and Sons, Brightside Works—steel, marine specialities. The latter declare a dividend of 5 per cent., which is at the same rate as last year. They report that business fell away somewhat during the middle of the year, and that the improvement now being experienced was in the latter months of 1895. At the same time the business was larger than in the previous years, although the profits were not proportionately increased. Messrs. Cammell and Co. pay 10 per cent., which is 2½ per cent. more than last year. The directors state that during the past six months a general improvement in the business operations of the company has been experienced, and the prospects for the coming year are of an encouraging character. The Solway Ironworks, Maryport, Cumberland, consisting of three blast furnaces, and their appurtenances, have been purchased by the company, who will find them a valuable adjunct to their Derwent Iron and Steel Works at Workington, as well as their hematite ore mines.

Earle's Shipbuilding and Engineering Company, Hull, the shares of which are considerably held in the Sheffield district, write to the Sheffield Press that the orders they have received from the Admiralty are for two of the third-class cruisers under the Goschen scheme, and not a remnant of the Spencer programme, as supposed by some. "These ships," it is added, "are a development from the torpedo boat catchers, or, as they are now better known, torpedo gunboats. They may, indeed, be taken as a cross between a modern cruiser and a torpedo gunboat, and are intended more particularly for service in shallow seas and in rivers, chiefly, of course, for police duties, although their armament will enable them to do good service in a fight with forts or cruisers." They are to be 300ft. long, 36ft. 6in. broad, and 21ft. 1½in. moulded depth, with a mean draught of water, when finished, of 13ft. 6in., and a displacement of 2135 tons. Their engines will be twin-screw, of the high-speed type, capable of developing 7000-indicated horse-power, which will maintain a speed of 20 knots per hour; the boilers, Thornycroft water-tube, for a working pressure of 300 lb. per square inch. For their defence, a thick protective steel deck, armoured conning tower, &c.; armament, eight quick-firing guns, and two torpedo tubes.

THE NORTH OF ENGLAND

(*From our own Correspondent.*)

A MORE active condition of trade has been reported this week than for some weeks past, and consumers generally are showing more disposition to buy. A good business is being done in nearly all branches of the iron and allied industries, and prices are again tending upwards, though they are not actually any higher now than they were last week. However, buyers more readily pay what is asked, especially where they want the iron for forward delivery, as there is no doubt that business is improving substantially. This is clearly indicated locally by the great increase in the traffic receipts of the North-Eastern Railway Company, though it is to be remembered that the figures over the current quarter have compared with a time last year when trade was hampered in an extraordinary degree by the severe weather. Making allowances, however, for that, there is a very large increase of traffic.

In addition to this the exports of pig iron from the Cleveland district are much above a March average, in fact they form a record for that month, as they will also for the current quarter, seeing that the deliveries in January and February were heavy for the time of the year. This month to Wednesday night 55,517 tons of pig iron were shipped from the Cleveland district, as compared with 42,833 tons last month, and 36,752 tons in the corresponding month of last year. Specially good are the over sea deliveries, which is due to the fact that not only has trade and consumption increased abroad, but, on account of the mild weather which has been experienced over the winter, many ports are open which are usually closed at this period of the year. It is believed that the consumption of Cleveland pig iron is now in excess of the production, and thus a decrease in stocks is expected to be reported at the close of the month. Large shipments of rails and manufactured iron from the district are reported.

The price at which the bulk of the business in No. 3 Cleveland G.M.B. pig iron has this week been done has been 38s. 6d. for prompt f.o.b. delivery, a figure which has practically ruled all the month; but there are now more buyers than sellers at the price, and more has to be given to most of the makers. Second hands are not doing much at present in the way of underselling the producers. For next quarter's delivery 38s. 9d. would be accepted by most sellers, and a considerable amount of business at that price has been done. Messrs. James Watson and Co., of Middlesbrough, have secured an order for 6000 tons of Cleveland pig iron for the East India Railway Company. Last year a similar order went to Messrs. William Jacks and Co., Middlesbrough. No. 1 Cleveland pig is at 39s. 6d. per ton, for early f.o.b. delivery. No. 4 foundry pig iron is stiffening in value because of the rapidly increasing demand for castings, and the scarcity of this quality of iron. Fully 37s. 6d. per ton is paid for it, while 37s. is realised for grey forge, 36s. 6d. for mottled, and 36s. for white, all early f.o.b. delivery. Cleveland warrants have been at 38s. 10d. cash, the best price that has ruled this year, but at the close on Wednesday buyers were offering only 38s. 6½d. cash. Very little iron is going into the public stores this month; on Wednesday night Messrs. Connal and Co. had 187,780 tons of Cleveland pig iron, the increase for the month being but 2270 tons. Mixed numbers of Cleveland hematite pig iron are obtainable in small quantities from merchants at 46s. 6d. for prompt f.o.b. delivery, but makers generally hold out for 47s. prompt and 47s. 3d. next quarter. There is, however, not quite so brisk a business doing in hematite pig as there is in Cleveland ordinary iron, and it is believed that more is being made than is required, but there are no means of verifying this belief, as no statistics of stocks are compiled, as in the case of Cleveland ordinary iron. The Tees-side Iron and Engine Works Company a few days ago blew out a furnace which required relining, but this week they have put in operation another furnace which has just been relined. Thus they have again two furnaces working, both on hematite iron.

A company, it is rumoured, has been formed for the purpose of acquiring and working the Coatham Ironworks. These are now in the hands of the National Provincial Bank of England, who offered them for sale by auction last year, but could not get a single bid for them. The works consist of two blast furnaces which have been idle since September, 1886. They were erected in 1873, when prices were at unprecedented figures, No. 3 Cleveland pig iron being at 120s. per ton—against 38s. 6d. now—and labour and materials were very far beyond their normal prices. Thus these works cost a very large sum of money. It is hardly likely that the works could be ready for commencing to manufacture pig iron for a year to come, even if preparations were at once made to put them in order. They need relining, and probably new boilers and stoves, so that a heavy sum of money would have to be spent on them. With trade so active, and prospects so encouraging, it is not unlikely that every available furnace in the district will be set to work as soon as possible.

The steel trade is very steady, and most pronounced is the improvement in the rail trade, in consequence of which manufacturers are not disposed to accept less than £4 15s. per ton net at works for heavy steel rails. The North-Eastern Steel Company, Middlesbrough, after a stoppage of five weeks, has completed its alterations and extensions, and resumed operations on Monday. It can now produce 3000 tons of steel weekly, or 25 per cent. more than previously, and the plant in Middlesbrough is capable at present of turning out 8000 tons of rails per week. The improvement in the rail trade has led to the expectation that the Darlington Steel Works, which have been idle since October, 1894, will be reopened shortly. The directors have the question under consideration.

The steel plate trade is satisfactory, though as regards demand there is rather a lull, which, however, cannot last long, taking into account the large amount of shipbuilding work that has been recently distributed, both for private owners and for the British Admiralty. Palmer's Shipbuilding and Iron Company, Jarrow-on-Tyne, has orders to build for the latter two cruisers, and Sir W. G. Armstrong, Mitchell, and Co., Elswick-on-Tyne, one cruiser, each to cost £180,000. Shipbuilders are quoting higher prices, and this is needful, as they have to pay higher wages. All the shipwrights in the North of England have had their wages advanced 1s. 6d. per week. Sir Raylton Dixon and Co., Middlesbrough, who are not connected with the Masters' Association, have had their men on strike on this question. The men wanted an unconditional advance of 1s. 6d. per week. The firm offered 2s. advance for a year, and this being refused, 2s. to the end of July and 2s. 6d. to the end of September, but the men refused to depart from the terms of the general settlement. However, they have agreed to an offer of 2s. 6d. per week advance, and they interpret this to mean 1s. 6d. advance—the same as the general advance—and 1s. bonus. That is how they get over their departure from the general settlement. The overtime dispute in the engineering industry of the Tees district has been settled, each day is to stand by itself. The general wages question among the engineers is likely to be adjusted without any difficulty. The masters' offer is now under the consideration of the men. It is reported that the Darlington Forge Company contemplate the starting of an engineering department in connection with their extensive establishment.

The Middlesbrough Exchange Company pays a dividend of 3½ per cent. to the shareholders on last year's account. One of the leading banks in the North of England—Messrs. J. Backhouse and Co.—is to be incorporated with Messrs. Barclay, Bevan, and Co.

Messrs. Charles J. Bagley, manager of the Moor Steel and Ironworks, and C. J. Watson-Munro, managing director of the Stockton Malleable Iron and Steel Company, have been added to the roll of Justices of the Peace for the borough of Stockton.

The extension of the Shildon Works by the North-Eastern Railway Company will, it is calculated, cost over £80,000, and when completed, 500 additional hands will be employed. The project is being carried out with a view to the centralisation of the wagon-building and repairing operations of the company, this work at present being distributed between York, Shildon, and Gateshead. In connection with the work Messrs. Shewell and Co., of Darlington, will supply 500 tons of steel work, and 220 tons of cast iron-work, at a cost of about £7000. The extensions include five large shops to be erected parallel with the engine-shed; a building shop, 300ft. by 60ft.; two machinery shops, 300ft. by 49ft.; an iron machine shop, 300ft. by 47ft.; and a wheel lathe shop, 300ft. by 47ft.

The death took place last Friday of Mr. George Crawshay, who for many years was head of the famous works of Hawks, Crawshay, and Co., at Gateshead. His age was 76 years. The works were founded in 1748 by Mr. Wm. Hawks, and when they were closed in 1889 covered 47 acres of ground. The firm were iron manufacturers, ironfounders, engineers, and boilermakers, builders of iron and steel bridges, lighthouses, and piers, anchor manufacturers, &c. The first Nasmyth hammer ever erected in England was put up at these works. The firm constructed the High-level Bridge at Newcastle in 1849, rebuilt the famous iron bridge at Sunderland, the Lindal Bridge at York. They erected no fewer than ninety bridges for the Caucasian Railways, the Golden Horn Pontoon Bridge, Constantinople. It is calculated that between 1848 and 1889 Messrs. Hawks, Crawshay, and Co. constructed 45,000 bridges. They also turned out fifteen large lighthouses for stations in England, Ireland, India, Australia, and the China Seas. They employed at one time 3500 workmen.

A somewhat better report is generally given of the steam coal trade, but the prices remain poor, best Northumberland being at 7s. 9d. prompt and 8s. 3d. over the season. The Durham coal trade is quiet. The Rowton Colliery, near Houghton-le-Spring, is to be closed, and in connection therewith the Marquis of Londonderry, the lessee, has taken the men into his confidence, explaining why he has been compelled to take this step. The coal is nearly exhausted, and the pit is very expensive to work on account of the great quantity of water to be pumped. It appears that last year the receipts were only £56,739, whereas the expenses were £72,380, thus showing a loss of about £15,640. The quantity of coal sold was 163,074 tons, and the loss per ton was close upon 2s. Of the £72,380 expended, £53,033 went for wages, or more than two-thirds, the cost of wages per ton of coal being 6/6·5—an exceedingly high rate. Under such circumstances, it could hardly be expected that operations would be carried on. It is believed that the North-Eastern Railway Co. will make some reduction in the dues at its Tyne Dock, to attract some of the traffic that is going to the Dunstan Staiths, which is so large there that it can with difficulty be coped with. Coke is very firm, and the supply is hardly adequate to the requirements. Middlesbrough ironmasters are paying from 13s. to 14s. per ton, delivered, for best brands.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market opened steady, with a moderate business, about former rates. Dealers appeared to be making up their minds that a time of quiet trade and regular prices might very likely be experienced, when the news came that the ship joiners had voted by a large majority against the masters' offer of a farthing per hour advance. This occurrence immediately suggested the likelihood of a fresh strike on the Clyde and at Belfast, and a renewed serious interruption to work. The bears attempted to take advantage of the situation, and increasing quantities of warrants changed hands, with the result that the upward tendency of prices was arrested, and a reaction appeared to be at hand. While the output of iron is greater than is required to meet the current trade, and considerable additions are being made to stocks, the latter are smaller than at this time last year, and much less than has been the case in former times. Taking this into account, along with the increasing consumption of raw iron at home, a very large fall in prices is perhaps unlikely at this time, even although the strike should take place. Business was done in Scotch warrants from 47s. 4½d. to 47s. 6½d., and back to 47s. 3½d. cash. Cleveland iron varied from 38s. 7½d. to 38s. 10d., and down to 38s. 8d., while Cumberland hematite sold from 48s. 9½d. to 49s., receding to 48s. 9½d. cash.

There are 41 furnaces making ordinary, 35 hematite, and three basic iron, total 79, compared with 75 at this time last year. In the course of the past week 2000 tons of Scotch pig iron were added to the stock in Connal and Co.'s Glasgow stores, but the stocks are comparatively small, while the demand is very good on the part of home consumers.

The values of the special brands of makers' iron are steady:—Govan, Monkland, and Carnbroe, Nos. 1, are quoted f.o.b. at Glasgow, 48s. 6d.; No. 3, 47s.; Gartsherrie, Calder, and Summerlee, Nos. 1, 51s.; No. 3, 48s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Coltness, No. 1, 53s. 6d.; No. 3, 49s.; Glengarnock, at Ardrossan, No. 1, 51s.; No. 3, 47s.; Eglinton, No. 1, 48s. 6d.; No. 3, 46s. 6d.; Dalmellington, at Ayr, No. 1, 48s.; No. 3, 46s.; Shotts, at Leith, No. 1, 52s. 6d.; No. 3, 48s. 6d.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

The pig iron shipments from Scottish ports in the past week amounted to 7985 tons, compared with 5219 tons in the same week of 1895. The United States took 15 tons, South America 150, India 100, Australia 110, France 180, Germany 956, Holland 665, Belgium 85, Spain and Portugal 122, China and Japan 150, other countries 400, the coastwise shipments being 5052, against 3116 tons in the corresponding week.

The engineering and foundry trades are making progress in the direction of greater activity, and merchants are doing better both with manufactured iron and steel. The malleable iron and steel works are now fully occupied, and inquiries are constant and important. Sellers are not able, however, to obtain such prices as they could desire or as they really need. There is some prospect of the demand ere long overtaking the supply so thoroughly that higher prices may be obtained, and this is all the more likely because a number of the works have already reached their highest capacity of output. Steel angles are quoted £5, and ship plates £5 7s. 6d. to £5 10s. per ton, subject to 5 per cent. discount for delivery in Glasgow district.

There is no improvement in the condition of the coal trade. The shipments of the past week from the whole of the Scottish ports aggregated 104,742 tons, compared with 119,875 in the preceding week, and 118,371 in the corresponding week of last year. A brisk inquiry has lately been experienced from the Clyde to Mediterranean ports, and full advantage could not be taken of it owing to a scarcity of suitable and ready tonnage. Latest advices from Alexandria, however, are to the effect that the coal trade there is weak. In the meantime, the recent spurt has firmed up the price of better qualities of shipping coal. For other sorts the rates quoted are nominal, and concessions have to be made in order to secure contracts of any importance. There is an increasing consumption at home in the West of Scotland. In Fifeshire, trade is just a little more hopeful in some of its aspects. There are promising inquiries from Russia, but the competition with the North of England is very keen, and while the miners are restricted to two and three days a week—only having four days in some places—stocks continue to accumulate at the collieries.

The traders in coals in the West of Scotland sent a request about a month ago to the directors of the Caledonian Railway Company that the rates on the carriage of coal to Leith should be reduced by 3d. per ton. They pointed out that four boats of over 1500 tons could be accommodated at Grangemouth, while in recent years the carrying of coals had been more and more by large steamers of from 3000 to 6000 tons. The Leith Dock Commissioners are now making extensions that will admit of the accommodation of the largest steamers. No further reduction, the memorialists said, could reasonably be expected in the dock charges at Leith, which are now the lowest on the Firth of Forth, but they represented to the railway directors that the latter could afford to reduce 3d. per ton and still leave a profitable margin for their company.

The secretary to the Lanarkshire Coalmasters' Association has just received a communication from the manager of the Caledonian Railway, in which he states that, after full consideration of the whole circumstances, his directors cannot see their way to comply with the request. He adds, however, that the company is at present arranging to provide additional accommodation at Grangemouth, to admit of a considerably larger tonnage being dealt with than hitherto.

The reduction of 6d. a day has been quietly accepted by the colliers. Indeed, there was no alternative open to them, as they are without funds to enable them to present any resistance.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE "discharge note" system and the Plymouth colliers' strike form the two prominent incidents of the week. Last week I submitted in this column that, seeing the strong opposition offered to the "discharge note" by the colliers, who were stoutly supported by "Mabon" in their opposition, the Associated Coalowners would be well advised in withdrawing it, and then framing some other substitute that would give honest and industrious workmen an advantage over the idle and irregular. I am glad to note that this view was adopted at several owners' meetings of late, Sir William T. Lewis especially recommending it. Some lively times have taken place in advocacy and opposition, and at the last gathering of workmen's representatives it was decided by 63 to 53 to wait a fortnight, and see what course the Associated Owners would consent to. The minority of representatives advocated an immediate strike, and Mabon was denounced as playing the workmen false. He is one of the most judicious of leaders, and yet with the strong aggressive spirit and suspicious nature of the men he has to do with, has all his work to maintain his government. After doing admirable service on the "discharge note" system, Sir William T. Lewis, Bart., proceeded on Tuesday to a conference at Plymouth with the strikers, and, I am assured by excellent authority, laboured ably to bring about an arrangement, but ineffectually. The latest news is that both management and men continue firm. Actions are pending against the company by some of the men, and one point insisted upon by the management is that these shall first be withdrawn. In the meanwhile, the circuit for obtaining support is being widened, and public aid is not volunteered so promptly as needed, the growing opinion being that there should be a consent to an arbitration, by which both should abide.

Capt. Rosser, late deputy, has been appointed dock master at the Bute Docks in place of the late and esteemed Capt. Pomeroy, and a new appointment has been made in addition, that of superintendent of the docks and railways, a position wisely given to Mr. James Hurman, late traffic manager on the Taff Vale Railway. It was always thought that Mr. Hurman would have succeeded to the head of the Taff Vale Railway at the death of Mr. Geo. Fisher, but the ways and moods of railway directors, like that ascribed to corporate bodies, are often mysterious. Cardiff strongly endorses both appointments.

As may be imagined, the well-grounded fears of a coal strike have not been without their influence upon the trade. Mid-week it was noticeable on 'Change, Cardiff, that there was considerable anxiety shown to close for requirements. The stormy weather has also continued to tell; yet, notwithstanding, last week showed a good total from Cardiff ports of over 300,000 tons.

Large cargoes have especially been in evidence. Two 6000-ton steamers have been cleared from Newport for Bombay, and several large ones are loading at Cardiff for the same destination. One despatched, Tuesday, Knight Bachelor, carried 9000 tons.

One of the novelties of the coal shipping of late was in the shipment of coal from Cardiff for New York. This was 1952 tons in the Mexican Prince. Last year the principal coal customer with Cardiff was Genoa, taking 913,779 tons. Port Said next, 890,362; St. Nazaire third, with 402,228 tons.

Swansea coal shipments last week were again small, due principally to non-arrival of tonnage. The total was only about 21,000 tons. Newport total, 62,080 tons; foreign, 1917 tons, coastwise.

Prices remain in a tolerably firm condition, slighly varying as ill rumours are circulated or withdrawn. This week Cardiff prices are as follows:—Best steam, 10s. 3d. to 10s. 6d.; seconds, 9s. 6d. to 10s.; drys, 9s. to 9s. 6d.; best Monmouthshire, 8s. to 8s. 6d.; seconds, 8s.; best small, 4s. 9d. to 5s.; seconds, 4s. to 4s. 3d.; drys, 3s. 6d. to 4s. House coal is easier, and it was remarked on 'Change, Cardiff, this week, that a better inquiry was being made for shipment, but that inland sales were beginning the "down grade." Best coal is selling at 10s. 6d. to 10s. 9d.; No. 3 Rhondda, 9s. 6d. to 9s. 9d.; brush, 7s. 9d. to 8s.; small, 6s. to 6s. 3d.; No. 2 Rhondda, 7s. 6d. to 7s. 9d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 6d. Patent fuel: Cardiff, 10s. to 10s. 6d.; Swansea, 9s. 9d. to 10s. 3d.; trade moderately brisk. Best Monmouthshire coal is selling at 8s. to 8s. 6d.; seconds, 8s.; sale rather slow and quotations maintained with difficulty. Eastern valley coal, 7s. 9d. to 8s. 1½d.

Good news reigns at all the principal works in the finished iron and steel department. The make varies from rails, sleepers, sheet iron, and small goods, with a lessened turn-out in several quarters of steel bars for tin-plate centres. In respect of this it may be added that great care is required and exercised in tin bar transactions, one or two tin-plate works having failed with large items owing to ironmasters. At one a compromise of 5s. in the £1 was offered but refused, and the tin-plate manufacturer has filed his petition. These are matters which debtors and creditors alike deplore, but, as all admit, the wonder is, considering the times and the great difficulty in dealing with the men, that cases of the sort are not more numerous. Taking the whole district, there are a large number of tin-plate works idle. In the Llanelly district temporary stoppages have been numerous, through the lack of orders, and it is stated that prices offered are such as will not warrant a restart. A statement current is to the effect that prices offered are so low that, even if the men conceded the fullest reduction asked for, it would not be worth while for makers to keep going.

In some districts men are showing a more general desire to meet the needs and requirements of tin-plate manufacturers. At the compact Cynon Works, Aberdare, the men have been working for some time at a concession on their part of 12½ per cent. Last week a demand was made that this should be increased to 20 per cent., but this was refused. Now I hear that an amicable arrangement has been arrived at by which the works will be kept going at a 15 per cent. reduction. In the Briton Ferry district eighteen mills were at work last week, five at the Villiers, four at the Vernon, three at Baglan Bay, three at Gwalia, and three at Earlswood.

There was a little better shipment of plates last week, the total reaching 52,906 boxes, while only 43,366 boxes came from works. Stocks are now down to 181,391 boxes. The clearances were to France and other parts of the Continent, Singapore, Java, and the United States. Loadings are now going on for Russia (Batoum).

A much better make of steel rails is going on at several of the leading steel works than used to be noted. This week a shipment of rails—520 tons—took place from Cardiff to Pernambuco, and 400 tons pig iron to Hamburg.

Iron ore is in good demand, three cargoes from Cyfarthfa, two from Dowlais, and one each from Blaenavon and Ebbw Vale came in during the early part of the week. Cardiff prices are:—Best Rubio, 11s. 9d.; Tafna, 11s. 3d.; Garucha, 10s. 9d. to 11s., c.i.f. Swansea quotations are:—Tafna, 11s. 3d.; Rubio, 12s. 3d., ex ship, cash thirty days.

On 'Change, Swansea, this week, the following were the latest general quotations:—Glasgow warrants, slightly higher, 47s. 5½d.; Middlesbrough, No. 3, 38s. 10d.; prompt hematite, 46s. 4d.; Welsh bars, £5 10s. to £5 15s.; sheet iron, £6 15s. to £6 17s. 6d.; steel, £6 12s. 6d. to £6 15s.; steel rails, heavy, £4 10s. to £4 15s.; light, £4 17s. 6d. to £5 7s. 6d. Bessemer steel: tin-plate bars, £3 17s. 6d.; Siemens best, £3 18s. Tin-plates, Bessemer steel coke, 9s. 1½d. to 9s. 3d.; Siemens, 9s. 3d. to 9s. 6d.; ternes, per double box, 28 by 20 C, 17s. 6d. to 22s. 6d.; best charcoal, 12s. 6d. to 13s. 6d. Block tin, £60 12s. 6d. to £60 15s. Lead, English, £11 to £11 2s. 6d.; Spanish, £10 17s. 6d. to £11.

Swansea coal quotations are:—Anthracite, 8s. to 11s. 6d. according to quality. Steam, 9s. 6d. to 10s. 3d.; second quality, 8s. 9d. to 9s. 3d. No. 3, Rhondda, 10s. to 10s. 6d.; No. 2, 8s. 9d. 9s. 6d. Coke is in brisk demand at Cardiff, furnace, 13s. 6d. to 14s. 9d.; foundry, 15s. 6d. to 16s. 6d.; special, 19s. 6d. to 20s.

At Cardiff prices of pitwood are slightly firmer, sales are being effected at 15s. 4½d.

The Welsh plate trade threatens to be revolutionised. Mr. Thomas, of Menai Bridge, has patented an invention by which the rock can be cut into squares of any size, without blasting operations. It is claimed that the machine will, at a trifling cost, perform the work of 400 men. Present cost of labour is 35s. per ton; future cost, £1. A practical trial is stated to have been most successful, and a syndicate is to be formed.

The Barry line to Pontypridd was opened for passenger service on Monday, and all passed off well.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

SATISFACTORY accounts continue to be received from most of the iron markets over here. Trade in iron and steel is steadily improving all round, and, judging from the number of contracts that have been booked within the last few weeks, full employment is assured to the majority of the works for several months to come. Prices are very firm, and generally tend upwards.

Last week was a brisk one in the Silesian iron trade. Spring demand on local account is already setting in freely, and it is anticipated that in April or May foreign inquiries will also increase, Poland and Russia having hitherto bought only small lots. Compared to last autumn, a rise of about M. 4 p.t. is noticeable for the different sorts of malleable iron. Manufacturers give an extremely satisfactory account of their business, the orders that have been secured reaching far into the third quarter, so that, if there should be a temporary lull with regard to new work, the activity at the mills will, nevertheless, be well maintained. Local demand for plates has been exceptionally good of late, owing to the brisk employment in the enamelling industry, which has been steadily improving since July last year. Among the heavier sort of plates, those for shipbuilding and boilermaking purposes are best inquired for.

Production of pit coal in Upper Silesia is statistically stated to have been, since 1865, as under:—

	Output. Tons.	Coal-pits.	Colliers.
1865	4,250,927	87	17,059
1875	8,228,369	122	32,198
1885	12,842,128	79	40,214
1895	18,066,401	53	53,760

The Austro-Hungarian iron market is, on the whole, in a fair condition. The orders that come in for structural iron have increased in weight as well as in numbers, and there is a lively activity going on at the mills and foundries. In the railway and bridge-building department prospects are good. Official quotations do not show any alteration. According to the *Buda-Pesther Correspondenz*, the opening of the Iron Gates across the Danube will take place on September 27th of present year.

During the last weeks the firmness on the French iron market has rather increased. The demand for pig iron has been very active, and stocks are small accordingly. The condition of the iron market is generally expected to remain satisfactory for several years to come, the more so because the large Paris exhibitions always have a favourable and lasting influence on trade. Orders for the Exhibition in 1900 are being looked forward to, and it is to be hoped that the confidence in the future may not be troubled by political events.

In Belgium demand and sale on the iron market are satisfactory, both on home and on foreign account. Quotations exhibit a rising inclination. Belgian foreign trade in iron and steel during the year now past was as under:—

	Import.		Export.	
	1895. Tons.	1894. Tons.	1895. Tons.	1894. Tons.
Iron ore	1,857,623	1,942,883	328,427	258,529
Raw steel	18,605	18,518	1,316	659
Drawn steel wire	7,172	—	610	—
Steel girders	569	681	54,125	23,146
Steel rails	441	234	86,452	78,717
Bars	9,205	11,126	29,895	18,906
Steel nails	5	—	6,372	—
Manufactured steel	1,115	1,028	20,955	34,839
Pig iron	225,665	227,428	9,865	12,057
Scrap iron	28,744	24,704	12,532	8,491
Iron wire	4,684	6,335	754	1,227
Iron girders	266	696	34,968	47,108
Iron rails	38	32	133	187
Iron plates	3,079	2,136	64,068	68,561
Iron bars	9,901	11,808	170,713	162,810
Iron nails	799	683	5,396	8,017
Hardware	4,147	3,859	34,576	25,358
Castings	1,274	1,116	23,322	22,328
Rolling stock	1,418	1,785	29,266	29,729
Machines	22,660	20,349	25,288	35,611

In every branch of the Rhenish-Westphalian iron industry there is a steady improvement to be noticed. Orders are plentiful, with good prospects of remaining so through summer, and perhaps for longer. With regard to the iron ore trade, both the Siegerland and Nassau mines are in brisk activity, prices being firmly maintained. Further advances in quotations have, however, not taken place, spathose iron ore fetching M. 8·60 p.t.; roasted ditto, M. 12 to 13 p.t.; calcined iron ore costs M. 12 to 14 p.t. net at mines. Minette of Lorraine is in animated request at M. 2·50 to 2·70 and 3·20 p.t., according to qualities. The demand for raw iron has been extremely brisk upon the week, and the lately raised quotations are willingly paid. For spiegeleisen, 10 to 12 p.c. grade, M. 54 to 55 p.t. is given; forge pig, No. 1, is offered at M. 49 to 52 p.t.; in some instances M. 53 p.t. has been realised; No. 3 is quoted M. 42 p.t.; hematite, M. 65 p.t.; foundry pig, No. 1, M. 65 p.t.; No. 3, M. 57 p.t.; basic, M. 54 p.t.; German Bessemer, M. 56 to 59 p.t. at works. Luxemburg forge pig is sold at M. 46·50 p.t. free Luxemburg. Much life is shown in the malleable iron trade, and business during the week has been brisk, foreign consumers coming forward very freely with their orders. Prices, though on an average M. 5 p.t. higher than formerly, yield but little profit. In most cases the contracts secured for bars reach far into the third quarter. In girders and hoops, likewise, a rise in demand has been noticeable. Steel makers are very busy on plates, sheets, and rails, inland and foreign demand being good. Wire and wire nails are in somewhat better request at the former low quotations; rivets also show a slight improvement. The activity at the machine and wagon shops is satisfactory.

Present list quotations, per ton at works, are as under:—Good merchant bars, M 115; angles, M. 120 to 125; girders, M. 80 to 90, and higher; hoops, M. 123 to 125; billets in basic and Bessemer, M. 83 to 85; heavy plates, for boilermaking purposes, M. 160; tank do., M. 135 to 140; steel plates, M. 130 to 135; tank do., M. 115 to 130; sheets, M. 145 to 155; the same in steel, M. 135; iron wire rods, common quality, M. 125; drawn wire in iron or steel, M. 118 to 125; wire nails, M. 127 to 130; rivets, M. 165 to 170; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 200; steel rails, M. 108 to 110; steel sleepers, M. 106; fish-plates, M. 112 to 120; light section rails, M. 98.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

GOOD attendance on 'Change. Steam coal in moderate demand, but shipments for the past week reached 81,000 tons; prices remain steady. House coal is without any alteration in demand or price. Tin-plates without any improvement. Manufactured iron and steel continue in good demand.

Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 8s.; house coal, best, 10s. to 10s. 3d.; dock screenings, 5s.; colliery small, 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 47s. 2½d.; hematite warrants, 41s. 7½d., f.o.b. Cumberland; Middlesbrough No. 3, 38s. 8d., prompt; Middlesbrough hematite, 46s. 1½d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 15s.; light ditto, £5 to £5 5s. f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 2s. 6d., all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s.; Siemens coke finish, 9s. 3d.; ternes, per double box, 28 by 20 C, 21s. to 22s. Pitwood, 15s. 3d. to 15s. 6d. Freights firm.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, March 12th.

THE gross earnings of our railroad mileage in 1895 was 75,000,000 dols. over the gross earnings of 1894. This year's gross earnings, it is estimated, will be 125,000,000 dols. over 1894 at least. Traffic on railroads is steadily increasing. The increase in January gross earnings was 10 per cent. over January. 1895. Bank clearings increased 6½ per cent. last week, but were 17½ per cent. less than same time 1893. The industrial situation is not altogether gratifying. General demand is backward. Prices in iron, steel, cotton cloths, petroleum, lead, hides, tin, wheat, corn, oats, and a number of other products have declined. Movements of cotton since September 1st at all United States ports foot up 4,528,703 bales, against 5,931,689 bales last year. The present lull may suddenly disappear. The business public, however, has no faith in the present administration, and a strong movement is on foot to place in authority an administration which is in harmony with the interests of 14,000,000 voters, as against the interests of a few hundred bankers. The tendency of the steel market is downward. Very few summer contracts have been placed. A sudden upward turn of prices is probable, because of the policy of so many large consumers to defer purchasing until material is actually needed. So much American railway mileage is in a condition that will render it an unimportant factor. Needs for equipment are urgent enough, but earnings forbid buying except for most urgent wants. In two months 12,500 freight cars were ordered. Plate mills, however, are quite busy, and pipe works are sold up. The metals are dull, and copper mines are restricting. Rail mills are working to less than half capacity. Apart from present despondency over the tardy development of spring trade, there is a hopeful feeling. It is either full speed or down brakes in America. The brakes are on just now.

THE Tower Publishing Company announce the publication this week of the "Naval Pocket Book," by Mr. W. Laird Clowes, containing a description of every warship in the world.

LAUNCHES AND TRIAL TRIPS.

On the 11th inst. the official speed trials of the twin-screw barge-loading dredger St. Austell, recently constructed by Messrs. William Simons and Co., Renfrew, to the order of the Admiralty, took place on the measured distance at Skelmorlie with very satisfactory results. Six runs were made with and against the tide, when it was found that fully a knot more than the contract speed was obtained. The Admiralty were represented by Messrs. Harris, Hay, Stewart, and Scoggins. The vessel left immediately thereafter for H.M. Dockyard, Devonport, where she is to be employed.

On the 17th Messrs. Wm. Simons and Co., Renfrew, launched the first of three steam hopper barges recently ordered from them by the Admiralty for service at Devonport. Its dimensions are as follows:—Length, 160ft.; breadth, 28ft. 6in.; depth, 12ft. 6in. The vessel is capable of carrying 570 tons deadweight, and is propelled by one pair of compound surface-condensing engines of indicated horse-power sufficient to propel the vessel when fully loaded at a speed of about nine knots per hour. There were present at the launch her Majesty's surveyors, Messrs. Hay and Scoggins, under whose direction the vessel was built. The berth in the yard will be occupied by a large and powerful stationary barge loading dredger recently ordered by the Mersey Docks and Harbour Board.

On Saturday, March 14th, the steel spar deck screw steamer Chun Sang, built by Sir Raylton Dixon and Co., Cleveland Dockyard, Middlesbrough, for the Indo-China Steam Navigation Company, of London, proceeded to sea under the command of Captain Evans for her official trial trip. This vessel, which has been especially designed and equipped for the company's trade in China, is 300ft. by 40ft. by 25ft., and has a deadweight carrying capacity of about 3400 tons, with arrangements in 'tween decks for carrying Chinese passengers. The spar deck is of steel sheathed with teak, and the bridge and forecastle decks are also of teak. Engines, of the most approved triple-expansion type, are by Messrs. the North-Eastern Marine Engineering Company, Sunderland, and the boilers are fitted with forced draught on Howden's system. The hull and machinery have been constructed under the supervision of Mr. Buchanan and Mr. Duncan. Mr. James Keswick, of Messrs. Jardine, Matthieson and Co., Mr. Cheyne, secretary of the Indo-China Steam Navigation Co., and others were on board during the trial trip, which passed off most successfully.

On the 17th inst. Messrs. Ropner and Son, of Stockton-on-Tees, launched a steel screw steamer of the following dimensions, viz.:—Length between perpendiculars, 290ft.; breadth, extreme, 43ft.; moulded depth, 19ft. 9in.; which they have built for Messrs. J. S. Allison and Co., West Hartlepool. The steamer is built off the part awning deck rule, with poop and raised quarter deck, her deadweight carrying capacity being 3500 tons on 18½ft. The saloon and cabins for captain and officers are fitted in the poop, the engineers' accommodation being amidship. She is built on the webb frame principle, leaving the holds entirely clear for cargo, and carries her water ballast in a cellular bottom and in the after peak. All labour-saving appliances are fitted for the economical working of the steamer, and also for the expeditious loading and unloading of cargoes. She has steam steering gear amidship and screw gear aft, four powerful steam winches, two large donkey boilers, direct steam windlass, stockless anchors, &c. The engines will work up to about 900 effective horse-power, and are by Messrs. Thomas Richardson and Sons, Limited, having cylinders 21½in., 35in., and 59in. by 39in. stroke, steam being supplied by two large steel boilers working at 160 lb. pressure. Mrs. Allison, wife of the managing owner, named the steamer Dorothy.

The Valhalla is a fine steel screw steamer, and has been built by Messrs. William Gray and Co. to the order of Messrs. Herskind and Co., of West Hartlepool. She is the twenty-fifth vessel which the builders have supplied to this firm. Her principal dimensions are:—Length over all, 310ft.; breadth, 43ft.; depth, 19ft. 11in.; and she has been built to Lloyd's highest class. She is of the partial awning deck amidships type, with poop, raised quarter deck, and short well and forecastle, and fore and aft schooner rig. A cellular double bottom is fitted, and also an after peak tank for water ballast. The engines have been supplied by the Central Marine Engine Works of William Gray and Co., and are of their well-known triple-expansion type, having cylinders 22in., 35in., and 59in. diameter, with 39in. stroke, supplied with steam by two single-ended boilers, 14ft. diameter by 13ft. long, working at 160 lb. pressure per square inch. The vessel left the Tees, fully laden, early in the morning, and was manoeuvred in the bay for the purpose of adjusting compasses, &c., till about 10 a.m., when she was met by a tug from Hartlepool conveying the inspecting engineers and others interested. The trial which the vessel and her machinery then underwent was considered eminently satisfactory, the engines working with great smoothness, the bearings keeping perfectly cool, and the boilers maintaining an ample head of steam and remaining perfectly tight. The owners were represented by their inspecting engineer, Mr. Fothergill; the engine builders by Mr. Lindsay. After the trial the vessel proceeded with her cargo of rails on her first voyage to Bombay.

The trial trip of the steamer Golden Fleece, which is intended for the fruit trade between the West Indies and New York, took place on the 11th inst. between Blyth and the Tyne. She is a steamer 320ft. by 35ft. beam, by 26ft. depth of hold, and has just received very extensive alterations at the hands of the Blyth Shipbuilding Company, of Blyth, who have converted this vessel from an ordinary cattle-carrying boat into one of the finest and largest fruit carriers. As is well-known, the question of ventilating the holds is one of paramount importance in fruit steamers, and a new arrangement has been adopted in this vessel whereby all the air in the holds is renewed in less than one minute, and arranged in such a manner that a continuous current of air sweeps the holds from one side to another, so that no stagnant air can lodge in any particular place. Those who are acquainted with the trouble of ventilating ships are best able to comprehend what this means, and the difficulties which have had to be surmounted. The upper and lower 'tween decks are insulated all fore and aft. The complete ventilation of the holds has been effected partly by mechanical means, and partly by utilising the waste heat from the boilers, thus reducing the cost of such installations, which in this case deals with over 60,000 cubic feet of air per minute, and is believed to be the largest quantity of air dealt with in a ship up to the present date. In addition to the above, one of the holds has been fitted with a refrigerating plant on the ammonia system, which will be capable of keeping the temperature down, so as to prevent the overheating of the fruit. The alterations made in the main engines by the engineering establishment of the Blyth Shipbuilding Company have been of such an extensive character as to increase the speed of the vessel by 1½ knots over anything she has ever done before, while at the same time the alterations have tended to a very material reduction in the consumption of the fuel at former speeds. Messrs. Clarke, Chapman, and Company have fitted a complete system of electric light installation, both for the ship's use, passenger accommodation, and working of the holds. The speed which was obtained at the trial gave the owners, and the large party of invited guests, unqualified satisfaction. It is interesting to know that the first steamer carrying fruit from the West Indies to New York was built fourteen years' ago for the same owners, and had only a gross tonnage of 600 tons, while the trade has so developed since that time that the above-named steamer is now to be employed in the same service, and has a gross tonnage of about 2200 tons, being the largest steamer afloat for the exclusive carriage of fruit. The whole of the alterations above referred to, including the system of ventilation adopted in this vessel, has been made to the designs of Mr. George Walker, consulting engineer and naval architect, of London, under whose superintendence the work has been carried out. The Golden Fleece is owned by the Argonaut Steamship Company, of London, and immediately after her trial she proceeded on her voyage to Jamaica.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

4th March, 1896.

4902. Letter Card, J. S. and A. J. S. Catford, Kingston-on-Thames.
4903. Treatment of Paste, &c., Board, C. E. Preusse, London.
4904. Whip Socket, G. F. Norrington, London.
4905. Indoor Game, A. Collins, London.

5099. Brake Apparatus for Vehicles, H. Parker, London.
5100. Petroleum Lamps, C. Erber and Ungarische Metallwaaren und Lampenfabriks Aktien-Gesellschaft, London.
5101. Button for Wearing Apparel, A. Yole, Birmingham.
5102. Driving Gear for Velocipedes, G. M. Neighbour, London.
5103. Wick-tubes for Lamps, C. H. Gosling, London.
5104. Slider-boxes for Vestas, F. M. B. Bertram and G. Robinson, London.
5105. Spats, &c., F. A. Astor, London.
5106. Forming Rims for Wheels, H. Alvord, London.
5107. Can Openers, C. V. Zinn, London.
5108. Clothes-line Supports, J. B. Allen, London.
5109. Couches, R. Van Wicks, London.
5110. Cones for Water-closets, &c., S. T. Baster, London.
5111. Chaff Cutters, M. Pierce, London.
5112. Harvesters for Binding Sheafs, M. Pierce, London.
5113. Electro-plating Bath, S. Pitt.—(*W. B. Hollingshead, United States.*)
5114. Looms for Woven Fabrics, J. and H. De Lorge, London.
5115. Making-up of Packages, F. H. Fraser and W. J. Fraser and Co., London.
5116. Adjusting Devices, M. D. Rucker and F. C. Bryant, London.
5117. Batten Cleat for Ships' Holds, J. T. Oliver, London.
5118. Consolidated Fuel from Coal, H. C. B. Forester, London.
5119. Deodorising, &c., Mixture, W. Hanlon, London.
5120. Wheels for Vehicles, G. C. Marks.—(*C. Labbé, France.*)

7th March, 1896.

5121. Rouble Feather Renovator, M. R. Ruble and A. G. King, London.
5122. Fastening Pneumatic Tires, R. F. Chisholm, Birmingham.
5123. Extracting Gold, W. H. and R. Duncan, Shropshire.
5124. The Self-stopper, H. Coates, Manchester.
5125. Bottles to Prevent Refilling, D. A. Murdoch, Belfast.
5126. Multiple Stamping Hammer, F. Tremlett, Bristol.
5127. Steam Boiler Furnaces, C. Christmas, Birmingham.
5128. Pipe Unions for Hose Tubes, A. Sweetser, London.
5129. Altitude of Bodies, R. Scott, Newcastle-on-Tyne.
5130. Hat and other Pins, &c., J. A. Malan, Birmingham.
5131. Drive Chain, W. J. Fieldhouse, Birmingham.
5132. Mattress and Bedding, W. E. Clarke, Huddersfield.

5133. Separation of Oxygen from Air, L. Chapman, London.
5134. Obtaining Oxygen from Air, L. Chapman, London.
5135. Automatically Operating Cocks, L. Chapman, London.
5136. Gas Compressing Pumps, &c., L. Chapman, London.
5137. Merry-go-rounds, J. H. Blyth, Nottingham.
5138. Looms, W. T. Birchenough and A. Wood, Manchester.
5139. Picking Motions of Looms, G. Richardson, Manchester.
5140. Deep-sea Machine, C. M., H. S., and F. O. Mundahl, Newcastle-on-Tyne.
5141. Rails, N. de Gessler, London.
5142. Accord Zithers, J. Bröm, Glasgow.
5143. Driving Gear for Machinery, J. Parnall and Parnall and Sons, Bristol.
5144. Refrigerating Chambers, J. H. Spence, London.
5145. Bottles, O. Patterson, Glasgow.
5146. Apparatus for Throwing Life Lines, J. Murrie, Glasgow.
5147. Chimney Can, W. C. Faulds and G. B. Deas, Glasgow.
5148. Ascertaining Real Distances, G. Davis, Birmingham
5149. Woven Driving Belts, &c., J. C. Fisher, Manchester.
5150. Acetylene Gas Generator, J. F. Blakeley, near Dewsbury.
5151. Pistols, C. O. Ellis, E. W. Wilkinson, and F. Cashmore, London.
5152. Manufacture of Plate Springs, F. S. Bull, Sheffield.
5153. Printing, A. S. Young and W. Rumney and Co., Manchester.
5154. Laundry or Smoothing Irons, S. H. Eastburn, Manchester.
5155. Chairs for Joints of Rails, H. S. Knight, Teignmouth.
5156. Dyeing Skins, J. and H. Creamer, London.
5157. Paper-making Machines, &c., J. White, Glasgow.
5158. Looped Fabrics, H. A. Foster and R. Lee, Halifax.
5159. Cruet Stands, &c., C. T. Constantine, Birmingham.
5160. Manufacture of Gongs, E. Townshend, Birmingham.
5161. Prevention of Down Draughts, T. Smith, London.
5162. Self-acting Brake, J. H. Walton, London.
5163. Weaving Looms, W. T. and J. E. Wood, W. and J. H. Hall, and J. Thistlethwaithe, London.
5164. Shedding Motion of Looms, W. Thornton, London.
5165. Waste Salt, J. C. W. Stanley and A. W. Maxwell, London.
5166. Boiling Pans, J. C. W. Stanley and A. W. Maxwell, London.
5167. Dyeing Cotton, O. Imray.—(*The Society of Chemical Industry in Basle, Switzerland.*)
5168. Electrical Communication, A. C. Brown, R. Burn, and L. G. Tate, London.
5169. Apparatus for Superheating Steam, J. S. Booth, London.
5170. Spindles of Doubling Machinery, L. Hargreaves, London.
5171. Electric Arc Lamps, Electroliers, &c., B. R. Baker, London.
5172. Match Box Holder, D. Bridgeman-Metchim, London.
5173. Lifts, &c., H. C. Walker and C. W. Hildred, London.
5174. Apparatus for Preventing Accidents, L. Anidjah, London.
5175. Regulating Device for Boiling Pans, E. Hermann, London.
5176. Apparatus for Preventing Accidents, T. Marsden, Liverpool.
5177. Bolts for Doors, A. Hauck and H Kameke, Manchester.
5178. Locomotives, Tramcars, &c., E. Lever, Liverpool.
5179. Truss, T. Hilton, Manchester.
5180. Inflation of Pneumatic Tires, J. R. McKie, Liverpool.
5181. Tongs for Pickles, &c., J. Roberts, London.
5182. Valve, A. T. Thornthwaite, London.
5183. Holding Device for Lamp Glasses, J. L. MacLoughlin, London.
5184. Recovering Cyanides, G. P. Lewis and F. S. Cripps, London.
5185. Precipitation of Metals, R. T. Marshall and L. G. Attenborough, London.
5186. Preventing the Refilling of Bottles, H. E. Vipan, London.
5187. Stop Valves, E. Andersen and E. T. Fleron, London.
5188. Embossed Wall Paper, &c., W. Steadman, Glasgow.
5189. Attaching Twin Bedsteads, B. R. Peyton, London.
5190. Securing the Ends of Wire, &c., M. Voss, London.
5191. Electric Current Conductors, A. Petzenbürger, London.
5192. Revolvable Handles, Kuma, Ld. and S. B. Earle, London.
5193. A Lever Tool Appliance, &c., B. R. Peyton, London.
5194. Bunsen Burners, W. H. Wheatley.—(*C Schmid, Belgium.*)
5195. Production of Ozone, M. Otto, London.
5196. Explosive Motors, J. H. Richards, London.
5197. Purification of Saccharine Liquids, M. Otto, London.
5198. Fire Hose and like Couplings, A. E. Stove, London.
5199. Feeding Ruling Machines with Ink, F. Kirby, London.
5200. Collapsible Boxes, H. Norman, London.
5201. Valves for Rock Drills, T. E. Bickle, Plymouth.
5202. Steam Boiler, G. Goepel and J. Scheinhüttee, London.
5203. Igniting Devices for Gas Burners, A. Schwarzschild, London.
5204. Registering Apparatus, H. H. Lake.—(*H. Lange, Germany.*)
5205. Water-tube Steam Boilers, J. Simonis, London.
5206. Steam Generators, C. Pataky, London.

9th March, 1896.

207. Fire Grates, F. Rigby, Manchester.
5208. Head Lock for Bicycles, F. W. Doggett, Norwich.
5209. Collars for Personal Wear, W. H. J. Masding, Manchester.
5210. Window Fasteners, W. D. Pitt, London.
5211. Bottles, F. S. Willoughby and E. A. Edwards, Manchester.
5212. Paper Bag, W. C. Haigh, H. Luke, and R. McBurnie, Manchester.
5213. Steam Generators, H. Wilcke, Liverpool.
5214. Steam Traps, A. E. Jackson and J. P. Jackson, London.
5215. Stop Valve, J. C. Fountain and B. F. Schram, London.
5216. Fastening Tailboards of Wagons, S. W. Bell, London.
5217. Folding Hammock Supports, M. A. Bailey, London.
5218. Preserving Provisions, G. M. Keevil, Bath.
5219. Permanent Way for Railways, T. F. Cashin, London.
5220. Automatic Gas Meter Indicator, W. C. Warner, London.
5221. Shoes, H. S. Hadland, Bristol.
5222. Vacuum Tubes, D. Neale, London.
5223. Drying Bricks, J. Nash, Manchester.
5224. Fixing Points on Picks, &c., J. Barlow, Nottingham.
5225. Receiver, W. Hutchinson, Manchester.
5226. Mechanism for Quarrying Stone, J. Barrett, Keighley.
5227. Presses, F. Waite and Waite and Saville, Ld., Bradford.
5228. Using Water as a Prime Mover of Machinery, T. Burns, G. F. Addleshaw, and T. E. Hall, Newcastle-on-Tyne.
5229. Bedstead Joints, J. Whitehead, Birmingham.
5230. Castors, W. C. Morison, Birmingham.
5231. Liquid for Curling Hair, C. N. Walley, Manchester.
5232. Let-off Motions for Looms, R. Wilby, Huddersfield.
5233. Cycle Handles, H. Stone, Birmingham.
5234. Chimney Pots, J. H. Greenwood, Mansfield.
5235. Endless Rail, W. Gedney, Chesterfield.
5236. Opsimeter, T. C. Barfield, Leicester.
5237. Disinfecting and Deodorising Apparatus, J. T. Freestone, Liverpool.
5238. Metallic Squares, S. G. Edwards, Sheffield.
5239. Toy, J. B. Close, Sheffield.
5240. Toy Wheel, R. Dawson, Sheffield.
5241. Watches, J. Hawley, Birmingham.
5242. Button-hole for Shirt Fronts, L. W. Balck, London.
5243. Rests for Supporting Bicycles, J. Leach, Chorley.
5244. Tooth-brush Handles, G. F. Pierce and Warwick Bros., London.
5245. Bicycle Rest, T. Feran and W. J. Harley, Seaforth.
5246. Jewel Brass Polish, E. E. Edwards, Newport, Mon.
5247. Draught Muffle Furnace, J. R. Geith, Berlin.
5248. Internal Sectional Stoppers, G. Rydill, Sheffield.
5249. Drawing Boards, S. R. Mundell, Leeds.
5250. Self-threading Sewing Machine Needle, J. Gasson, Redhill.
5251. Cycle Handles, J. M. Gell, London.
5252. Securing of Bee Swarms, J. Sewell, Knaresbrough.
5253. Electro-deposition of Metals, S. O. Cowper-Coles, London.
5254. Machinery for Making Nails, O. E. Lewis, London.
5255. Clamp for Tailors' Patterns, G. E. Stanfield, London.
5256. Automatic Ignition Box, M. Robinson, Newcastle-on-Tyne.
5257. Syphon Flushing Cisterns, J. P. O'Donnell, London.
5258. Copying Apparatus, F. W. Zimer, London.
5259. Shoes, B. M. Tregaskes, London.
5260. Reduction of Refractory Ores, F. Ellershausen, London.
5261. Valve for Compressed Air Bags, J. Dormer, London.
5262. Carriers for Cash Checks, &c., H. A. Wheat, London.
5263. Electro-plating of Wood, H. A. V. Wirth, London.
5264. Toilet Requisite, A. P. A. Fincher and C. W. Burleigh, London.
5265. Manufacture of Armour Plates, J. H. Dickinson, London.
5266. Closing of Canisters, Boxes, &c., H. Mardon, London.
5267. Splint or Fracture Box, &c., T. G. Light, London.
5268. Colouring Matters, O. Imray.—(*The Society of Chemical Industry in Basle, Switzerland.*)
5269. Dog Muzzles, C. H. Lorberg, London.
5270. Glue-pots and Analogous Vessels, W. Wilson, London.
5271. Chair Bedstead, G. Stoermer, London.
5272. Combs, P. Schulz, London.
5273. Preservation of Tobacco, F. Hancock, Liverpool.
5274. Metals, A. S., T. A., R. J., and S. Smith, and T. Deakin, Birmingham.
5275. Applying Starch to Fabrics, W. A. E. Henrici, London.
5276. Pedals for Cycles and other Vehicles, R. W. Smith, Birmingham.
5277. Gas Control for Explosive Gas Motor, W. Donaldson, London.
5278. Machinery for Cutting Coal, C. W. Atkinson, London.
5279. Utilisation of Acetylene Gas, G. Ragot, London.
5280. Gulleys, W. J. Jennings, London.
5281. Traps, W. J. Jennings, London.
5282. Vehicle Shafts, W. A. Bromwich and C. A. Floyd, London.
5283. Tube, H. S. Ward, London.
5284. Beetling Machines, A. A. Whitley, London.
5285. Webs for Carrying Tea Leaf, W. Jackson, London.
5286. Women's Jackets or Coats, M. Frentzel, London.
5287. Feeding Boilers, T. A. Sergeant and G. Beck, London.
5288. Dress Fasteners, A. A. Wright, London.
5289. Pumps, S. B. Bamford, London.
5290. Pipes, J. M. Jacobs.—(*W. B. Haas and Co., France.*)
5291. Manufacture of Gas, A. Kitson, London.
5292. Locks, A. Karlik and F. Dworschak, London.
5293. Manufacture of Methyl Aldehyde, W. Gray, London.
5294. Seats for Velocipedes, H. J. B. Kendall, London.
5295. Lamps, J. A. Seaverns, London.
5296. Ammunition, W. Hope, London.
5297. Saddles for Bicycles, H. T. and F. T. Maw, London.
5298. Flash-light, Apparatus, A. J. Boult.—(*W. Bruns, United States.*)
5299. Screw-drivers, J. Reece, London.
5300. Slugging Machines, J. H. Southcott and J. Florey, London.
5301. Umbrellas, Parasols, &c., C. A. Markham, London.
5302. Catches for Retaining Handles, W. K. Birkinshaw, London.
5303. Bird Drinking Fountain, J. Popperwell, London.
5304. Cooling Serpentine with Dropping-tubes, J. H. Köhler, Berlin.
5305. Saddles, C. Szameitat, Hamburg.
5306. Preventing Glow-bodies being Damaged, F. A. F. Graefe, Hamburg.

10th March, 1896.

5307. Safety Gear for Colliery Cages, G. C. A. Dunnicliffe, Derby.
5308. Attachment for Saucepans, G. C. A. Dunnicliffe, Derby.
5309. Joints of Drain Pipes, &c., J. T. Briscoe, Enfield.
5310. Water-closet Apparatus, &c., J. Hulse, Cheshire.
5311. Fastening Parts of Cycles, A. E. Evans, Coventry.
5312. Covering Horticultural Houses, H. C. Board, Bristol.
5313. Boilers, W. N. Dack, Manchester.
5314. Insoles, R. Thomalla, Manchester.
5315. Electrically Dispatching Parcels, E. H. Seddon, Manchester.
5316. Cycle Gear Cases, W. H. Higgitt and W. Crowson, Birmingham.
5317. Boats' Booms and Lashings, W. Bell, Glasgow.
5318. Piano, A. Horobin, Colwyn Bay.
5319. Balls Used in the Game of Golf, W. L. Bullows, Birmingham.
5320. Attaching Terminal Wires, I. H. Parsons, Leicester.
5321. Steam Engines, G. Bendler, Glasgow.
5322. Water Gauge Glasses, J. A. and S. Fletcher, Manchester.
5323. Lubrication of Machinery, G. B. Goodfellow and E. A. Pickup, Manchester.
5324. Bridle Bits, J. Wedge, sen., J. Wedge, jun., and D. Wedge, Wolverhampton.
5325. Bridle Bits, A. Dewsbury, Wolverhampton.
5326. Rudders, W. Fairweather.—(*J. Ramsay, South America.*)
5327. Metallic Bale Coverings, M. A. Heath, Glasgow.
5328. Valves, C. W. Weiss and A. Meitz, London.
5329. Catches for Cages, R. Ashurst, Wigan.
5330. Moving Minerals, T. Wrigley, Todmorden.
5331. Working Friction Clutches, J. Atterton, Haverhill.
5332. Stoppers for Bottles and Jars, R. W. Rundle, London.
5333. Ventilating Ships, W. C. Morison, Birmingham.
5334. Measuring Apparatus for Liquors, H. J. S. Cross, Jersey.
5335. Imitation of Stained Glass, N. Macphail, Glasgow.
5336. Increasing Illuminating Power of Gas, R. Lavender and W. Tice, London.
5337. Handles for Metal Dish Covers, S. Worrall, Sheffield.
5338. Gear Cases for Cycles, G. E. Mansell, Birmingham.
5339. Rims and Guards of Wheels, W. H. Barton, Coventry.
5340. Photographic Camera Shutters, E. S. B. Hughes, Glasgow.
5341. Home Trainer, C. M. Farrow, Glasgow.
5342. Candlesticks or Candle Holders, W. F. Fletcher, Birmingham.
5343. Fire-escape, W. Grosvenor-Bradley, Manchester.
5344. Change of Development in Cycles, J. Bénazet, Brussels.
5345. Gramme Ring Armatures, R. Holiday and J. Freeman, Barnsley.
5246 Metal Surfacing Tools, F. H. Payne, London.
5347. Mirrors, F. Restall, London.
5348. Paper Fasteners, J. Hewitt and F. R. Baker, London.
5349. "Brillium," G. F. Pierce and Warrick Bros., London.
5350. Key-hole Guide, R. P. Cato, Birkenhead.
5351. Parlour Games, T. Thompson, London.
5352. Imitation Football, T. Thompson, London.
5353. Stone-sawing Machinery, G. and J. Rushworth, London.
5354. Indoor Games, A. C. Douse and E. Bailey, Nottingham.
5355. Cigar Holders, A. M. Hogg and J. C. T. Murray, London.
5356. Door Handles, H. Kerr, Glasgow.
5357. Machines for Topping, &c., Turnips, P. Allan, Glasgow.
5358. Treating Low Qualities of Iron, L. Pszczolka, London.
5359. Envelope Opener, H. J. Watts, M. T. Gameson, and W. Haslam, London.
5360. Ankle Supports for Skates, &c., B. A. Dorst, London.
5361. Chest Expander, E. Thomson, London.
5362. New Game of Lawn Trapette, W. J. Barrat, London.
5363. Apparatus for Rolling Cigarettes, S. P. Rose, London.
5364. Tires and Rims of Cycle Wheels, M. F. Hutton, London.
5365. Duplicate Safety Balloon, H. E. Robinson, London.
5366. Pulley for Roller Blinds, W. and J. T. Timmins, London.
5367. Centrifugal Churns, E. Fugeman, London.
5368. Incandescent Gas Burners, J. H. H. Duncan, London.
5369. Umbrellas and Walking Sticks, L. Clement, London.
5370. Sewing Machines, H. H. Lake.—(*F. W. Whitcher, United States.*)
5371. Spinning Machines, F. S. Culver, London.
5372. Advertising Devices, H. H. Lake.—(*T. G. Daly and N. Estevez, United States.*)
5373. Spike, T. McCherry, London.
5374. Brake Shoes, W. D. Sargent, London.
5375. Apparatus for Generating Gas, E. T. Turney, London.
5376. Cotton Openers, H. S. Houghton, London.
5377. Football Cases or Covers, W. K. Reid, London.
5378. Securing Cycle Lamps to their Brackets, A. J. Simpson, Birmingham.
5379. Transparent Drawing Plate, &c., G. Davis, Birmingham.
5380. Incinerators, W. Defries and V. I. Feeny, London.
5381. Disinfecting, &c., Sewage Matter, P. O Dowd, London.
5382. Safety Bit for Stopping Horses, &c., G. Nobes, London.
5383. Spray Producer, G. Nobes, London.
5384. Engines, R. D. Knight, London.
5385. Method of Making Cigarettes, L. H. Sondheim, London.
5386. Building Bricks, O. Kleinberger, London.
5387. Candle Holders, T. Woof, London.
5388. Chaff Cutters, E. E. Bentall, London.
5389. Call System for Use with Autographic Telegraph Apparatus, H. F. Jackson.—(*H. Etheridge, United States.*)
5390. Skirt Supporting Device for Lady Cyclists, F. B. Shuttleworth, London.
5391. Apparatus for Heating Water, H. McPhail, London.
5392. Producing Moire on Ready-woven Fabrics, O. Pastor, London.
5393. Generation of Motive Power, C. Guattari and The Guattari Power Syndicate, London.
5394. Velocipede Saddles, J. V. Pugh, London.
5395. Coating and Colouring Pins, J. B. Finnemore, London.
5396. Hydrants, &c., E. Hochedez and T. Faivre, London.
5397. Artificial Leg, H. Heinecke and B. Herting, London.
5398. Weighing, &c., Machine, W. H. Doble and G. W. Watson, London.
5399. Weighing, &c., Machine, W. H. Doble and G. W. Watson, London.
5400. Fire-extinguishers, W. P. Thompson.—(*W. J. Herron, United States.*
5401. Boxes for Postal Purposes, W. P. Thompson.—(*E. Blanco, Italy.*)
5402. Stencils for Painting, &c., L. Hintz, London.
5403. Draw-plate Ovens, J. Horton and W. Price, Manchester.
5404. Chimney Tops, J. Walker, Liverpool.
5405. Pneumatic Tires, W. Hughes and A. Royle, Liverpool.
5406. Manufacture of Corsets, T. W. Wyatt and J. H. Smith, London.
5407. Process for Preserving Eggs, O. Leupold, Liverpool.
5408. Telegraphic Relays, W. S. Smith and W. P. Granville, London.
5409. Furnaces, S. Pitt.—(*La Compagnie Internationale des Procédés Adolphe Seigle, France.*)
5410. Shafts for Carriages, &c., M. F. J. Willemin, London.
5411. Artificial Skins, F. C. Tussaud, London.
5412. Telephones, T. McKenna.—(*H. L. Webb, United States.*)
5413. Disinfecting Clothing, W. J. Frazer and Co. and L. McG. Frazer, London.
5414. Preventing Railway Accidents, H. Biermann, London
5415. Projecting Serpentines, A. J. Boult.—(*C. Brünot,————*)
5416. Strainers, W. Tyree, London.
5417. Copying Maps and Drawings by Hand, W. Tyree, London.
5418. Curtains, W. Tyree, London.
5119. Shearing Machines, W. Tyree.—(*J. Sands, Australia.*)
5420 Supporting Articles, W. Tyree.—(*W. Bartlett, Australia.*)
5421. Bedsteads, W. Tyree.—(*J. F. Stephenson, Australia.*)
5422. Washers for Bottle Stoppers, C. H. Gray, London.

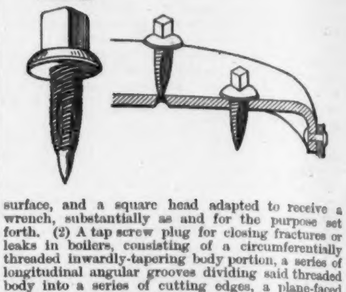
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

551,354. Tap Screw Plug, *J. Lee, Plymouth, Pa.—Filed May 31st*, 1895.

Claim.—(1) A tap screw plug for closing fractures or leaks in boilers, consisting of a circumferentially threaded inwardly tapering body portion, a series of longitudinal, angular grooves dividing said threaded body into a series of cutting edges, a plane-faced pointed inner end, a circumferential cap near its outer end having a flat under face and a convex upper surface, and a square head adapted to receive a wrench, substantially as and for the purpose set forth. (2) A tap screw plug for closing fractures or leaks in boilers, consisting of a circumferentially threaded inwardly-tapering body portion, a series of longitudinal angular grooves dividing said threaded body into a series of cutting edges, a plane-faced pointed inner end, and a circumferential cap at its outer portion, substantially as and for the purpose set forth.

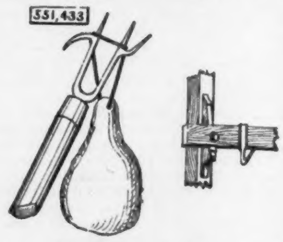
551,354



551,433. Lifting Fork, *E. A. Cozens, Toledo, Ohio.—Filed August 10th*, 1895.

Claim.—A lifting fork, comprising the handle, a two-pronged fork secured thereto, a branch projecting forwardly from one of said prongs, and a rearwardly curved branch projecting from the other of said prongs, said prongs and said branches lying substantially in the same plane, substantially as and for the purpose specified.

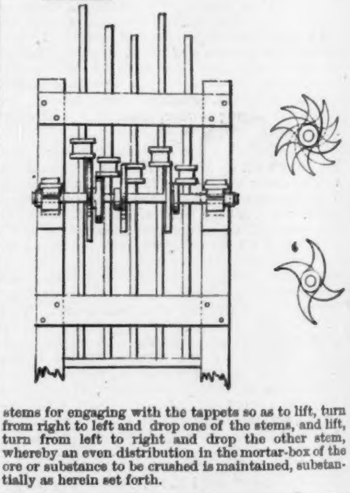
551,433



551,449. Stamp Battery, *C. Raleigh, Johannesburg, South African Republic.—Filed June 25th*, 1892.

Claim.—In a stamp battery or crushing mill, the combination, with two stamp stems and tappets mounted thereon, of a double cam between the two stems for engaging with the tappets so as to lift, turn from right to left and drop one of the stems, and lift, turn from left to right and drop the other stem, whereby an even distribution in the mortar-box of the ore or substance to be crushed is maintained, substantially as herein set forth.

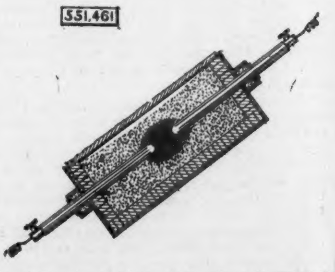
551,449



551,461. Art of Producing Carbide of Calcium, *W. C. Clarke, New York, N.Y.—Filed April 29th*, 1895.

Claim.—The hereinbefore described process of making carbide of calcium, which consists in causing current to pass between horizontally disposed electrodes, embedded in a mass of pulverised and intimately commingled lime and carbon, of such extent that a material proportion thereof will remain undecomposed by the passage of the current and gradually separating the electrodes as the material between them is reduced, so as to produce between the electrodes a body of the carbide surrounded by an undecomposed mass of the pulverulent mixture.

551,461



THE PROBLEM OF BRISTOL DOCKS.

DOCKISATION OF THE AVON.

THE question still, and for many years past, pressing upon the Bristol Corporation raises problems on which one eminent engineer after another in long succession has been called upon for an advisory report; and this by no means because of want of competence or lack of confidence in Mr. J. M. McCurrich, the present Docks Engineer, or either of his distinguished predecessors. The fact is that Bristol is endeavouring to reconcile the difficulties of its position as an inland riverside town with the changed conditions of a seaborne international trade, in which the vessels are yearly increasing in size, and demanding more than ever prompt facilities for loading and discharge. One of the oldest ports in our islands, and still a thriving and expanding city, it has, relatively speaking, found itself further and further removed from free access to the ocean highways of the world. The competition of Liverpool, the vigorous and more recent efforts of Southampton, the strenuous energies of Cardiff and the neighbouring ports on the Welsh coast, have told seriously upon the whilom supremacy of Bristol in the traffic of the Western Seas. The craft bearing the argosies which used to enrich Bristol merchants must have increased fourfold in dimensions since the port authorities first began to discover that younger rivals were forging ahead at its expense. Here were sailing vessels of from 3000 to 4000 tons carrying corn from North Pacific ports, and steamers of even larger tonnage bringing over other food stuffs from Argentina, Australia, or New York. The slight and tortuous river presented them with a constant danger when its water level did not impose an impossibility. The risk of sending a laden vessel round the Horseshoe Bend of the Avon shall be left to the appraisement of the members of Lloyd's; the impracticability of towing up a large corn-laden ship is proven by current experience, as well as admitted by the engineering reports. What, then, was Bristol to do? Should the agents of commerce in the city remove themselves and their merchandise nearer to the sea? Or should the City Fathers in their wisdom cause the sea to be brought into closer proximity to their ancient wharves and warehouses? In the latter case they would have had the example of Manchester to guide them; and that cannot yet be said to be altogether encouraging. As to transporting the traffic to the borders of the sea, the experiments made by the Docks Committee in building or acquiring the docks at Avonmouth and Portishead seemed to bid the boldest of the old school of merchant adventurers to hesitate and beware.

Between these two issues rests the rock on which the Bristol Corporation appears to be splitting, and yet these are issues on which the future welfare of the town must undoubtedly largely depend. The prosperity of Bristol is quite as much a matter of national concern as the prosperity of our own metropolis, or Glasgow, Manchester, and Liverpool. An old port which sent out Sebastian Cabot on his productive cruise, an immemorial river which was a haven for trade while most of our other ports were in their infancy, become points of quite sentimental interest at a moment when engineering science is called in to refit it, so to say, for the exacting requirements of to-day. But it is there, and on that sympathetic point, that the chief difficulty unpleasantly obtrudes itself. Bristol, at large, wants to maintain its old reputation, and resume the position in which it could distance or outrival its younger compeers. Bristol, in its dock-side community, has an idea that it would not be prudent to let its centre of commercial gravity be disturbed by an extension of its dock and wharfage accommodation towards the mouth of the river. One party is demanding the dockisation of the Avon, which would involve its dredging and straightening—to place it on a level with the approaches to the docks on the Mersey and Southampton Water. The other party desires to keep the trade concentrated in its present headquarters, on the higher reaches of the Avon, which most of us know as the site of the Bristol Docks. Both sides, one would like to assume, represent an equal amount of intelligence and an equal degree of the trading instinct. There, however, they have been at it, hammer and tongs, intermittently for a generation of normal life. There they are at it now, the Little-endians against the Big-endians. The commercial side of the controversy may be left to settle itself in the locality in which it arises. It is where the commercial men cannot agree that they have had to call in the advice of an expert engineer.

The original plan of Mr. McCurrich, the resident Docks Engineer, was described in THE ENGINEER on October 14th, 1892, page 320, before the Bristol Docks Bill of 1893 was presented to and inexplicably withdrawn from Parliament. Mr. McCurrich was supported by the advocates of a Greater Bristol. His scheme was opposed by an older fashioned set, on the ground that it would entail too vast an expense. It was under these circumstances that Mr. Wolfe Barry, C.B., was called into council, and given practically a free hand to criticise, amend, and generally advise. At the outset it has to be noted that his elaborate and instructive report, a summary of which we have already published, cuts the ground from under the feet of the gentlemen who condemned Mr. McCurrich's plans as too extravagant for immediate needs. He shows that if the Dock Engineer erred, it was in underrating the obstacles that would have to be encountered, and making his estimates out on too economical a scale. The proposals Mr. Wolfe Barry had to consider were substantially four, which may be stated in the ascending order of their importance:—(1) The improvement of the Avon by straightening and deepening it; (2) the extension of Avonmouth Dock; (3) the improvement of the approaches and enlargement of Portishead Dock, on the Somersetshire bank; and (4), which is probably the crux of the whole controversy, the plan of dockising the Avon at a point near its junction with the Severn at King-road. There is no need to compare Mr. Barry's statement of approximate cost with that of Mr. McCurrich. For the purpose of this article it is sufficient to take out Mr. Barry's figures, based upon surveys and calculations which seem to have been exhaustive :—

Avon improvements—alternative schemes	£93,000 or £140,000	
New dock at Avonmouth	£1,308,000	
Pier at Firefly Rock	£320,000	
		£1,628,000
Improvements at Portishead ...	£852,000	
Pier at Firefly Rock	£320,000	
		£1,172,000
Dockisation—St. George's Wharf scheme	£2,580,000	
Pier at Firefly Rock	£320,000	
		£2,900,000

But in either case these estimates are not inclusive of all the necessary costs of improving the navigation between Bristol and the sea. Mr. Barry adds: "In addition to the works themselves, and whether they are undertaken or not, I should strongly recommend the immediate installation of an efficient system of signalling and lighting the Avon generally, so as to bring it in this respect up to the standard of such a navigation as the Clyde, where vessels are never out of sight of beacons and leading lights, and can navigate with as great facility and security by night as by day. I am much struck with the almost total want of these conveniences between Avonmouth and Bristol, and cannot but think that their absence is a great drawback to the geographical advantages which Bristol possesses. Gas buoys, or small fixed lights, served by reservoirs of compressed gas, are easily and cheaply provided now-a-days, and I venture to urge their early adoption on the river Avon."

Undoubtedly the most important part of Mr. Barry's report is that in which he deals with the Dockisation of the river, and in connection therewith discusses the possibilities and requirements of a profitable Transatlantic passenger and mercantile traffic to Bristol port. He

says, positively enough, that it is impossible "by any extension of dock accommodation at Bristol itself to provide there for such large vessels as would be required for the service. If the river were not dockised, but merely deepened and improved in respect of curves, the tidal access would still involve too much risk to large vessels to render such a scheme practicable. If, on the other hand, the river were dockised, there would be no object in attempting to provide adequate accommodation for them at Bristol by expending large sums of money in improving the town docks and quays there." The advantages of dockising, in Mr. Barry's view, are:—(1) It would provide a large, deep, and commodious dock at the mouth of the river, the accommodation of which might be indefinitely extended; (2) it would make the navigation of the Avon easier and safer for all classes of ships for which the docks at Bristol are fitted; (3) it would give increased value to much of the land bordering on the river, though of course the amount of increase would depend entirely upon the question whether and to what extent trade would be developed by the execution of the work; and (4) the dockised river could be connected with Avonmouth Dock. so that the dock would have another and improved entrance to the Severn, which would be very desirable in view of the fact that Avonmouth Dock is now entirely dependent upon one entrance. But Mr. Barry adds:—"On the other hand, dockisation would be a very costly undertaking in itself, and would entail the diversion of the sewage of Bristol from the Avon, which alone is a formidable matter," as may be inferred from the fact that the drainage area of the Avon, and of the Frome above Bristol, must be taken at nearly 900 square miles, while the floods are frequently heavy, and descend with great rapidity. It would be rash to say that Mr. Wolfe Barry urges the dockisation project; but he shows more clearly perhaps than Mr. McCurrich that the objections to it relate mainly to expense, and not to engineering difficulties in the way of disposing of sewage and flood waters, or by reason of damage to the King-road anchorage through impounding or diverting the flushing forces of the stream. His proposal—shown on the accompanying plan No. 1—differs from that of Mr. McCurrich in selecting another site near St. George's Wharf for the proposed dam and sluice, because it would give a better foundation for masonry and the rest of the engineering works. The distance from the entrance lock to the two-fathom line of the Severn on the substituted plan would be 700 yards, or less than half the distance of the lock proposed by Mr. McCurrich, and the quay frontage could be made 6600ft. instead of 3700ft., at a moderate additional cost. The lock would be 85ft. wide and 800ft. in length, with 36ft. depth of water at high-water of neap tides. A dry dock Mr. Barry insists on as an essential part of the undertaking, and that could be used as a second entrance in case of emergency. A second lock, though too small for Atlantic liners—it is 450ft. by 62ft.—is already provided by means of the existing dock at Avonmouth. We have given Mr. Barry's general statement of the cost of dockising the Avon, and here are the details of his calculation:—

Cost of the works mentioned, at the St. George's Wharf site	£1,490,000
Railway lines, minor river improvements, sheds, cranes, land, and buildings...	190,000
Cost of sewerage works, provision for Frome floods, and additional accommodation at Bristol, as in Mr. McCurrich's report	700,000
Capitalised cost of dealing with floods and working the sluices, together with repairs and depreciation, say	100,000
Sundry expenses, superintendence, engineering, Parliamentary expenses, &c.	100,000
	£2,580,000

There was an alternative and less ambitious scheme propounded by the Dock Engineer in his report of April last year. That was to construct a basin and locks at the Horseshoe Bend, and is illustrated in our sketch map No. 2. It would give a basin of eleven acres in area, with two locks 400ft. and 500ft. long, by 70ft. and 90ft. wide respectively, the gates pointing upwards and downwards on the river; while another lock 300ft. long by 70ft. wide, with a passage 80ft. wide at the upper end of the basin, was to have been constructed on the land enclosed by the Horseshoe Bend. The cost of this work was put down by Mr. McCurrich at £700,000, exclusive of the graving dock which Mr. Barry regards as a necessary complement of any of the schemes; and the estimate, moreover, did not provide for the diversion of sewage or additional accommodation at Bristol town, which items Mr. Barry thinks would involve an additional £350,000. On this scheme it must suffice to quote the opinion of the expert, that "the work would be an expensive undertaking for comparatively limited results. Even if there were no elements of cost to be considered, I do not think," says Mr. Barry, "that the advantages of this proposal outweigh its disadvantages, and I cannot recommend it for adoption."

Then it is Dockisation, or what? Mr. Barry's report enters minutely into the competing claims of the supporters of dock extension on the Gloucestershire and Somersetshire shores at the embouchure of the river. Each project, he declares, is practicable; it is chiefly a question of cost. Of the two his preference inclines to Portishead. "If any works are to be undertaken for the use of Atlantic liners, it seems to me that the proposed enlargement of Portishead dock should be selected rather than either of the more expensive projects." The proposed entrance lock at Portishead would be only 430 yards from the two-fathom line, 700ft. long by 85ft. wide; and a graving dock could be made alongside the lock to serve as a second entrance in case of need. Being in close propinquity to the Firefly rock, Mr. Barry observes, "Atlantic liners would be able to go in and out of the dock with a minimum amount of trouble or interference to shipping, which in itself would be a great recommendation." The approximate costs of the works at Portishead, described in detail, are:—

Extension and improvement of dock, including graving dock	£687,000
Roads, railways, cranes, sheds, land, and buildings	100,000
Sundry expenses, superintendence, engineering, parliamentary expenses, &c. &c.	65,000
	£852,000

or, with £320,000 for the pier at Firefly rock, £1,172,000. Moreover, at what Mr. Barry calls "a moderate cost," the sills of the Portishead dock could be placed on a lower level by 5ft. than those at Avonmouth, with greater probability of making and maintaining the entrance channel. The annexed plan, No. 3, explains Mr. Barry's views of the works required in the case of Portishead. It remains to be seen what Bristol will do in the future as the result of the mass of useful engineering knowledge and suggestions the old port has elicited from the highest authorities, among whom Mr. Wolfe Barry is the last. For the present, the City Council has contented itself with adopting the least of Mr. Barry's proposals in voting for river improvement works at a cost not to exceed £93,000, which leaves the problem of the port very much where it was before Mr. Barry was consulted.

The Hull and District Institute of Engineers and Naval Architects.—At the last meeting of this Institution, Mr. F. Somerscales, of Earle's Shipbuilding and Engineering Company, read a paper, entitled "Ships' Cabins and their Fittings," Mr. F. H. Pearson, president, in the chair. The various designs and details of construction of ships' cabins and saloons, both above and below deck, were explained and illustrated, with the reasons for each method of construction and its attendant advantages and disadvantages. Attention was directed to the practical difficulties experienced in obtaining a satisfactory design when viewed from an architectural standpoint.

THE INSTITUTION OF NAVAL ARCHITECTS.

THE 37th annual session of the Institute of Naval Architects began on Wednesday, in the hall of the Society of Arts, John-street, Adelphi. There was an exellent attendance. The new President, the Earl of Hopetoun, occupied the chair. After the usual formal business had been transacted, Mr. Holmes, the Secretary, read the report of the Council for 1895-96. The finances of the Institution are in a satisfactory state. Much of the report is taken up with an account of the visit of the Institution last summer to Paris. We learn that the Council have received a cordial invitation from the President of the Chamber of Commerce of Hamburg, acting on behalf of a committee representing the government of the city and all its most important corporations, to hold the next summer meetings of the Institution in that important port and its neighbourhood. Encouraged by the success of their first visit outside the British Isles, the Council have accepted this invitation. The meetings will be held in the month of June, and full particulars will be published at as early a date as possible.

At the close of the Paris meeting, Lord Brassey, to the great regret of the Council, resigned the office of President of the Institution, as he was about to leave the country to take up the Governorship of Victoria. Acting under bye-law 41, the Council elected the Earl of Hopetoun, G.C.M.G., as President of the Institution till the close of the annual general meeting, and now proposed him for election as President by the members. Lord Hopetoun preceded Lord Brassey in the Governorship of Victoria. He is Paymaster-General, and represents the Admiralty in the House of Lords in the present Government. Like his predecessor in the chair, he is well qualified, both by his experience and by the deep interest which he takes in naval matters, to preside over this Institution. The Council having been approached in reference to the representation of shipbuilders and marine engineers in the technical department of the Board of Trade, and believing that their co-operation in this movement would be in accordance with the best interests of the profession, have appointed Dr. Francis Elgar and Mr. Archibald Denny as their representatives to co-operate with the representatives of other institutions and bodies for the purpose of furthering the object aimed at. The Council deeply regret to announce the death of one of the Vice-presidents, the late Dr. Peter Denny, and the resignation, through ill-health, of another Vice-president, Sir James Ramsden. The Institution has also to deplore the death of one of its members of Council, the late Sir Edward Harland. The death of Captain Le Clerc, naval attaché at the French Embassy, and one of the Associates, has caused much sorrow to his many friends in the Institution. His presence, both for his own sake and as the naval representative of a friendly Power, was always greatly appreciated at the meetings.

After the scrutiny of the balloting lists and some other business had been transacted, the President delivered his address. He began by congratulating the Council on what he might term a prosperity report. He gracefully alluded to the hospitality received in France last year, and was glad to welcome among them that day some of the gentlemen to whom they owed so much. After a reference to the death of Sir Edward Harland, Dr. Peter Denny, and Capt. Le Clerc, he spoke of the work done by Lord Brassey, and then went on to say:—It was now his duty briefly to allude to the chief events in the shipbuilding line which have taken place during the past year, or are taking place at the present time. The most striking event of the moment, and the one which must be foremost in their minds just now, is the programme of construction just made public by the Admiralty. Five new battleships are to be laid down; they are to be improved Renowns, their displacement is to be 12,900 tons. In offensive power they will be equal to the Majestic class; in speed and radius of action they are designed to have a slight advantage over that class, although their displacement will be some 2000 tons less. Some apology would be due from him for giving these figures, which must already be familiar, were it not that they recalled to his mind a very important point in the speech which their former President—Lord Brassey—delivered to them last year. He said, speaking of the Majestic class, "While fully recognising the superiority of the latest battleships, in a new programme it may not be superfluous to set forth the leading arguments in favour of keeping down dimensions, and distributing the fighting power of the fleet in a greater number of ships," and again, "as the ten ships now building are of the largest dimensions yet reached in naval architecture for war, our next batch of ten ships might well be of the type represented so admirably by the Renown." He quoted these words of Lord Brassey with the utmost respect, and it would seem at first sight as though the designs of these new ships, which we are about to build, were in some degree a concession to the views of those who advocate moderate dimension in our ships of war; but in his opinion they are a very direct and very excellent answer to those who favour a policy of building smaller ships than has been our wont of late. It is true that they are smaller by the size of a third-class cruiser than are the Majestics, but it has been necessary to make some sacrifices to attain this diminution of size. As far as he could learn, there is practically a consensus of opinion amongst naval experts, as also amongst foreign critics, that the ships of the Majestic class embody in the highest degree all that is most desirable in a British battleship; but people will say, if this is so, why not continue to build Majestics? No doubt we should do so, if the Majestics were suited to all of the multifarious duties which the British Navy has to perform. Events, however, over which we have no control, and the development of maritime powers which a few years ago were non-existent, have made it possible that our Navy may be called upon to act in waters unsuited to the great draught of the ships of the Majestic class. For these reasons it has been found necessary to design the new vessels with 2ft. less draught than the class mentioned, and with a displacement of 2000 tons less.

The four great requirements in a battleship are, without doubt, speed, radius of action, gun power, and defensive armour. History teaches us the importance which our forefathers attached to the weather-gauge. It was regarded by them as all-important to that fleet which hoped to assume the offensive; the weather-gauge of to-day is the power to out-steam the fleet of the enemy, the power to concentrate quickly, and bring on a general action at the most favourable moment. Coal supply, as limiting radius of action, is also of vital importance to the fleet which must keep at sea, and which must carry on operations at a great distance from its base. The gun power of these ships leaves nothing to be desired, as it equals that of their larger consorts. We now come to the price paid for the 2000 tons of displacement taken out of these new ships. It is a sacrifice of about 25 per cent. of defensive armour. The development of the quick-firing gun and of high explosives makes it essential that the guns of the secondary armament and their crews should be properly protected; and it has, therefore, been decided to make the reduction in the side armour, which is to be of 6in. instead of 9in., as in the Majestic class. This, then, is the sacrifice which our designers have had to make, and it is considered to be the least harmful sacrifice that could be made under the circumstances. He must not forget to mention, too, that these battleships will be the first that our Admiralty have fitted with water-tube boilers.

He then passed to the cruisers projected in the new programme, and here he felt himself in closer accord with those who advocated moderate dimensions; but, again, what are moderate dimensions? Ten years ago a cruiser of 10,000 tons would have been a monster. To-day it comes under the heading of moderate dimensions. The new cruisers are of 11,000 tons displacement; that is, about midway between the Blenheims, of 9000 tons, and the Powerfuls, of 14,000 tons. This excess of 2000 tons over the Blenheim class would seem to be devoted to the attainment of a higher continuous sea speed, a more perfect system of protection to the guns and ammunition supply, and to the sheathing and coppering of the ships' bottoms, in order that they may be able to keep the sea for a longer period without docking. The considerable offensive power which these vessels possess would enable them to cope with anything afloat save a modern battleship; and their great speed would enable them to avoid a conflict with an enemy superior to themselves. They should prove equal to making quick passages in heavy weather, and altogether they promise to be useful adjuncts to a fleet of heavy ships. He was quite aware that the wisdom of building these large and expensive cruisers without side armour at the water-line has been called into question, but he hardly thought that that was a fitting moment to discuss such a subject. After careful consideration, after exhaustive experiments, and after availing themselves of the best expert advice at their disposal, the Admiralty have for some time past deliberately elected to discard side armour in all our cruisers, and to rely on armoured decks and coal protection. In our new second-class cruisers we again find an example of the upward tendency of moderate dimensions. They are vessels of 5600 tons, which is the precise size of the Orlando class—the belted first-class cruisers of ten years ago.

The Admiralty have also the intention of building a large number of third-class cruisers of the Pelorus type—vessels of 2135 tons displacement, and with a speed of 20 knots. Although, on the whole, their design has been approved of, it has been urged that they should have greater length, in order to improve their coal endurance. He would point out that, as matters stand, they will be 20ft. longer than their prototyes—the Bellona class—and that their radius of action at 10 knots speed is calculated at 6000 miles, which may be considered entirely satisfactory for cruisers of their size, being twice that of the Bellonas. They have also a higher freeboard, and so will be better sea-keeping vessels than the Bellona, and will carry a more powerful armament. Any reference to the work in hand for the Royal Navy would be imperfect without a short notice concerning the torpedo boat destroyers built or building in private yeards for the Admiralty. They are the greatest novelty of our time, and each batch of these little vessels, when completed by the contractors, appears an improvement upon the last batch. To obtain a speed of 30 knots, or thereabouts, is such a marvellous achievement that the firms which have succeeded in accomplishing this feat deserve the highest credit, and the grateful thanks of the country.

In speaking of the work which has been done in connection with the Royal Navy during the past year, he could not help referring to the extraordinary rapidity with which her Majesty's first-class battleships Majestic and Magnificent have been built and fitted for sea. These ships were completed within two years of the date of their being laid down—a wonderful feat on the part of the Dockyard staff both at Portsmouth and Chatham. As he had already ventured to point out, these ships have won the entire approval of all naval officers, and they have exactly fulfilled the anticipations of their designer, Sir William White, who was about, he was glad to say, to return to his work restored to health after his long and serious illness. Fifty-nine ships of war, with a total displacement of 148,000 tons, were launched in 1895; of these fifty-one were built in private establishments and eight in the Royal Dockyards. These figures, of course, include warships built for foreign Governments. He did not think that there are any special features to chronicle in connection with the development of the mercantile marine during the past year; 528 steamers with an aggregate tonnage of 905,000 tons, and 53 sailing vessels with a tonnage of 46,000 tons constitute the output of the yards of the United Kingdom. The net increase during the past year in the tonnage of the world for mercantile purposes amounts to about 518,000 tons. A brief reference to the papers to be read at that meeting brought his address to a conclusion.

The first paper read was that by Captain Lord Charles Beresford on water-tight doors, which was immediately followed by another on the same subject by Colonel Soliani, one of the most eminent constructors of the Italian Navy. The papers will be found in other pages. The discussions on both papers were taken together, and were unusually interesting and amusing. They occupied the whole afternoon, to the exclusion of all other business, and were principally remarkable for the fact that they had little or nothing to do with the construction of water-tight doors; the point fought over being, first, the necessity for openings of any kind in bulkheads; and, secondly, whether the naval officers or the constructive department provided them. Admiral Wilson began. He said that he could speak with some authority, as he had commanded the Sanspareil, which is a sister ship to the unfortunate Victoria. He held that the first point to be considered was, that a ship should be able to withstand the attack of one torpedo at least. If blockading, she might very readily have a hole blown in her bottom, which would flood a compartment or two; but if she could then make for a port, she might have the hole stopped in a couple of days and return to duty. He did not believe in doors, because they never were shut when wanted. A man did not expect to be run over by an omnibus in the street, and did not provide for such a contingency. In the same way captains of ships did not provide for being rammed or blown up. He would have a ship divided into a few large compartments, between which there should be no doors. This might be subdivided, and fitted with doors in the subdivisions, but he did not think they would be needed. Thus the engines and boilers could be in one compartment, torpedoes in another, heavy ammunition in another, and so on. The great need for doors was to avoid hatchways in the armour deck. He had examined into the condition of the Sanspareil after the loss of the Victoria, and found that if she had a compartment athwartships filled with 1000 tons of water, it would sink her 2ft., but she would be upright; but if she carried half that quantity to starboard, say, it would heel her so as to sink her starboard side 6¼ft. The sub-division of a ship must be fatal. He had no doubt that the small compartments in the Victoria caused her to capsize. If the water had not all been at one side she would have floated upright, but down by the head, for a much longer time, so that life might have been saved. The Sanspareil was much safer with all four boiler compartments full than with only one full. Admiral Makaroff used tin plate models, with tin boxes to represent compartments, in studying new designs.

Sir William White on rising was received with a storm of congratulatory applause, and soon showed that he had lost none of his old power of debate. In a very amusing speech he sought to turn the tables on Lord Charles Beresford. The gallant admiral, he said, took the case of a ship with 208 water-tight doors, but after he had done all he could to get rid of them, he only disposed of nineteen. A report was drawn up by naval officers concerning the water-tight doors of the Royal Sovereign, and these gentlemen only succeeded in dispensing with one door out of a total of 200. He quite agreed that there ought to be as few doors as possible, but how few would do? It was not the construction department that provided the doors, but the naval officers who insisted on having them. He had heard what Admiral Wilson had said, but the obvious course to be adopted by Admiral Wilson or any captain was to lock any doors believed to be unnecessary, but the locking was a thing not done. He then went into the history of the whole subject, and said that history was repeating itself. Twenty years ago and more the whole subject had been thrashed out by Sir N. Barnaby, and proposals identical with those of Lord C. Beresford had been fully discussed. Officers continually demanded more and more doors; coal had to be moved; ammunition had to be moved; ventilation had to be considered. The defect of Lord C. Beresford's arguments was that they were excellent, but they did not deal with all the questions that had to be considered. As to the closing of doors, he thought Lord Charles Beresford was scarcely fair to the crews, and he believed that they really did close and fasten doors when they said they did so.

Admiral FitzGerald set his hearers laughing by a reference to our worthy contemporary *Punch*. The whole question of doors was very old. He was surprised at the line taken by Lord Charles Beresford. In the Collingwood there were very few doors provided, the bulkheads being for the most part solid, but that ship was so uninhabitable in consequence, that doorways had to be cut in the bulkheads. As for Lord C. Beresford's doors, with a little ladder at each side, they reminded him of the monkey-on-a-stick given to children, but chief engineers in the Navy were not built that way, and could not use such doors. The efficiency of a ship depended on the accumulated convenience of her internal arrangements.

Admiral Freemantle went over old ground. Proceeding, he said that the ship surgeons must have a voice in the matter, and that a ship could not be kept healthy without adequate ventilatioin and communcation. He detailed an experiment which he had carried out, which showed that, with good discipline on board a large ironclad, all doors could be closed and properly secured in one minute and a-half. He had tried Sir W. White's plan of locking certain doors in a ship which he commanded, but the exigencies of living compelled him to relax his regulations, and he had to open them.

Admiral Colomb reviewed the discussion, and then dealt with the question of bulkheads, and detailed his experience with a sluice valve in one. He was followed by Mr. Martell, who explained "Lloyd's" practice. He advocated for warships the division of the ship into large compartments, each complete in itself, without doors in the transverse bulkheads. The steam pipes were a difficulty, and he would take them up on deck from the boilers and down again to the engine-room over the tops of the bulkheads.

Mr. Seaton, as an engineer, supported Lord Charles Beresford's views, and referred to the loss of the Royal George and Admiral Kempenfeldt. That ship had no bulkheads or water-tight doors. She was lost through neglect, so might be any ship. Collision bulkheads had been fitted almost historically in merchant ships. There had been a collision between the old Black Prince and the Royal Oak about 1868; after repairs the forepeak of the latter ship had been filled with water to test the tightness of the bulkhead, and it had never been emptied, and the ship carried a couple of hundred tons of water there ever since until a year or two ago, when its presence was discovered by an inquisitive admiral who was bent on getting into the forepeak. The notion that engineers wanted doors out of pure cussedness was not true. He cited ships which he had built, with two boiler-rooms and one engine-room, all cut-off from each other completely, and he heard no complaints. He had to fit a mechanical telegraph to the boiler-rooms from the engine-room, signalling "half-speed," "full-speed," "stop," "more steam," and that was all.

Professor Biles referred at great length to the City of Paris and City of New York as Atlantic steamers, but not by name, and suggested that as the chief engineer of one was present, he should give his experience. Accordingly, the chief engineer of the City of Paris gave some of his experiences. He explained that there was no difficulty, because he had twenty-five engineers under him, including electricians. These were all divided into groups, and one group was provided for each compartment. When the chief of any group had occasion to go into another compartment, his place and authority was taken at once by the next of the group in rank, while he who visited another compartment, if of superior rank, to the man in command then superseded him for the time being. There was no friction, and no difficulty. Each group was responsible for its own compartment. In spite of the absence of bulkhead doors they managed to do very good work with great regularity. As an example of what they had to do, he might say that once, out of eight pumps which he had to feed nine boilers seven broke down, and left him with one 6in. double-acting pump, but they kept the ship going for several hours at 14 knots until they had effected repairs. It was a very anxious time, no doubt. The voice pipes from the boiler-rooms to the engine-rooms continually said, "Short of water here, sir," but they worried through. In his ship there were twenty-five engineers including the electricians; one chief—himself—three second engineers, six thirds, six fourths, and so on. The bulkhead matter, as far as regarded the engineers, was purely a question of proper organisation.

Mr. Martell called attention to the fact that there were four models of bulkhead doors to be seen by members.

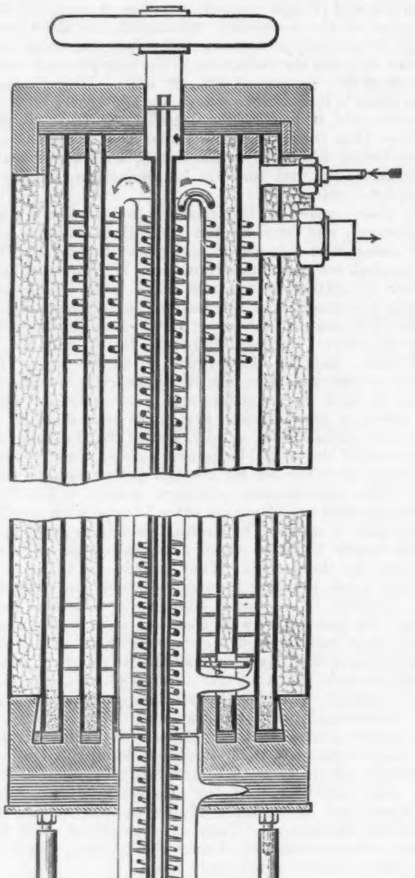
Lord Charles Beresford made a very effective and humorous speech in replying on the whole discussion. He said that as he and Admiral FitzGerald were both Irishmen, it was beyond the bounds of probability that they could agree on any subject whatever, and as to the 19 doors out of 208, these 19 doors were the essential doors. They were all low down in the vessel, a fact that Sir William White had overlooked. He held that the small doors he suggested supplied a ready means of communication by voice between compartments, and that if anyone did not like to go through them, he could go on deck out of one compartment and down the ladder into the next one. He repeated that doors never yet had been found of service when wanted, and that they had already cost the nation £3,000,000 and hundreds of valuable lives. No doubt naval officers were to blame for insisting on the use of too many doors. But it must not be forgotten that for years there had been no proper consultation between the naval officers and the constructors, and he took some credit to himself for bringing about a better state of affairs

After a brief reply from Col. Salviani, the meeting adjourned until yesterday—Thursday. We must hold over our report of the proceedings until next week.

The dinner of the Institution was held in the King's Hall of the Holborn Restaurant on Wednesday evening, the Right Hon. the Earl of Hopetoun presiding. There was a very large company present, including the Right Hon. Capt. Lord Chas. Beresford; Sir William Arrol; Sir E. Dawes, K.C.M.G.; Sir Raylton Dixon; Mons. Le Lt.-Colonel du Pontavice, Military Attaché and Acting Naval Attaché French Embassy; Mons. Emil Bertin, Directeur du Matériel, French Ministry of Marine; Mons. le Marquis de Chasseloup-Loubat; Mons. Le Comte de Bondy; Capt. G. Noel, R.N., Third Sea Lord of the Admiralty; Mons. V. Daymard, Vice-president de l'Institution Technique Maritime; Herr Dr. Sieveking, President Hanseatic Court of Appeal; Mons. G. Canet; Herr C. Ferd. Laeisy, President Hamburg Chamber of Commerce; Herr Adolph Woermann, President of the Hamburg Shipowners' Association; Ald. T. Richardson, Dr. Francis Elgar, Admiral the Right Hon. Sir John Dalrymple Hay, Bart.; Vice-Admirals G. Digby Morant, N. Bowden Smith, P. H. Colomb; Rear-Admirals Sir F. Bedford, K.C.B., Second Sea Lord of the Admiralty, Fitzgerald, A. K. Wilson, Admiral Boys; Messrs. A. E. Seaton, John Denny, M.P., J. I. Thornycroft, James Laing, B. Martell, E. Winsor Richards, J. Macfarlane Gray, A. Denny, and Prof. Biles. A letter from the Right Hon. G. J. Goschen, M.P., apologising for non-attendance, was read by the President, in which he expressed the hope of receiving another invitation from the Institution. After the usual loyal toasts, the President gave that of the "Naval and Military Forces," coupled with the name of Admiral Sir F. Bedford, who in the course of an amusing speech appealed to naval architects to leave them a little more space for exercising on the decks of warships. He spoke in high terms of the British system of training men for the Navy as opposed to foreign practice. Sir Edward J. Reed, in proposing the toast of the guests, said how glad they all were to see so large a gathering of foreign friends. This toast was responded to by Lieutenant-Colonel du Pontavice, M. E. Bertin, and Captain G. Noel. Mons. Bertin read a message from the President of the French Republic, in which the latter expressed the great interest he took in the Institution. Dr. Elgar was entrusted with the toast of the members from Hamburg, who had invited the Institution to make the town their rendezvous for the coming summer's meeting. This toast was replied to by Dr. Sieveking.

THE HAMPSON SYSTEM OF LIQUEFYING GASES.

IN our impression for October 4th, 1895, we described, for the first time in England, the remarkable system of liquefying gases invented by Dr. Linde, whose name is well known in connection with refrigerating apparatus. In a subsequent issue we dealt with the subject of regenerative cold. On Saturday last Dr. Hampson gave before several scientific men and practical engineers a demonstration of his process for liquefying gases at Brin's Oxygen Works in Westminster. It is, of course, no part of our business to pronounce an opinion as to priority of invention or the validity of patents. Dr. Hampson claims to have anticipated Dr. Linde by several months, and to all intents and purposes the apparatus which both Linde and Hampson use is identical, and the description of the Linde process, which we have already published, will apply accurately to that of Dr. Hampson, save in a few details. The nozzle used by Dr. Hampson, instead of being fitted with a regulating cone, is provided with a nearly flat valve or plate obturator worked by a screw, as shown in the accompanying engraving. In this way Dr. Hampson states that all risk of plugging with ice is avoided.



HAMPSON'S APPARATUS FOR LIQUEFYING GASES.

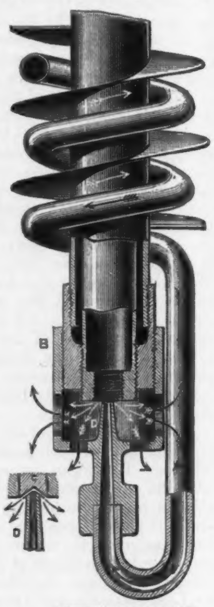
Dr. Hampson's experiments were in every respect satisfactory. We reproduce here the words of a paper which was placed in the hands of the visitors.

Oxygen is delivered to the apparatus at a pressure of 120 atmospheres, and at ordinary temperature, no carbonic acid, nitrous oxide, or other artificial cooling agent being, as heretofore, employed either inside or outside the apparatus. The gas is compressed into the apparatus and there allowed to expand, and thus become slightly cooler. This moderate refrigeration is increased by Dr. Hampson's self-intensifying process in an apparatus measuring only 28in. deep and 7in. diameter, until it is sufficient to liquefy the gas at atmospheric pressure at the rate of about seven cubic centimetres in four minutes. The process is as follows:—The whole of the gas, after being cooled by expansion, immediately surrounds the pipe through which the compressed gas is passing to the point of expansion, and so makes this gas, which is still compressed, cooler than it was itself while in compression. This cooler compressed gas consequently becomes at the point of expansion cooler than that which preceded it, and in its turn follows backwards the course of the still compressed gas, and so makes the latter cooler than ever before expansion, and, therefore, also cooler than ever, after expansion. This intensification of cooling—always assuming sufficient protection against external heat—is only limited by the liquefaction of the gas; the temperature of liquefaction being, in the case of oxygen, 180 deg. Cent.

The following striking experiments were performed with the liquid oxygen, thus rapidly and cheaply produced, which, however, are not in themselves new:—Quicksilver instantly frozen, and then hammered out flat, like a piece of lead, melted as it warmed. Ether and alcohol instantly frozen. Soft india-rubber so hardened by the cold that it was pounded into powder by a hammer, like a piece of brick. Piece of brass cooled so that on dipping it into water it immediately became thickly coated with ice, the ice-covering increased for a long time by freezing moisture out of the atmosphere.

These substances—like all others—at ordinary temperature are hot enough to boil off a quantity of the liquid oxygen, which on coming in contact with the air produced a cloud of ice-mist by freezing the moisture in the air. The lip of the vessel in which it was contained was thickly covered with hoar-frost, being hot enough to boil the liquid as it was poured over. The liquid falling on the ground, did not wet it for a moment, but darted rapidly, like quicksilver, in all directions, disappearing in a cloud of ice-mist.

Dr. Hampson holds, he states, the earliest patent for liquefaction of air. It has been found that suggestions have been made in times past of possibilities in the way of producing increased cold by means of the application of the cold produced in well-known commercial processes to the further cooling of the compressed gas, but it had never before been proposed to employ the whole of the cold of expansion of the gas to cool the compressed gas continuously and so to attain the highest degree of cooling possible to the gaseous state. This is believed to be the first complete demonstration in England of the efficiency of this process in producing a degree of cold limited only by a change of state of the gas cooled, without the aid of any extraneous artificial refrigeration Dr. Hampson's drawings and descriptions were prepared in April, 1894, and his patent is dated May 23rd, 1895. As a question of priority appears to be involved, we must content ourselves with a bare statement of the circumstances. We have already so fully dealt with the theory of the process that it is unnecessary to say more concerning it. The very simple set of apparatus which we saw at work acted perfectly. In our engravings, the large view shows the apparatus, and the above enlarged views show the central pipe and the end of the coil A, fitted with the jet piece D, which delivers the compressed gas against a flat plug on the end of a spindle, which screws in at C. The separate little view shows a different form of the jet D, and the end of the plug C.



DETAIL OF VALVE

THE MANCHESTER SHIP CANAL AND THE IRISH TRADE.

MANCHESTER has not hitherto been able to secure the advantage of direct trade with Ireland. The general merchandise traffic which passes between England and Ireland is mostly carried in steamers either owned by railway companies or worked under conference arrangements with the railway companies. The traffic is carried between interior towns in England and Ireland respectively at through rates, the amounts of the through rate being divided between the railway companies and the steamship companies under a mileage arrangement, the amounts accruing to the railway companies out of the through rates being considerably less than the rates locally charged between the interior towns and the ports.

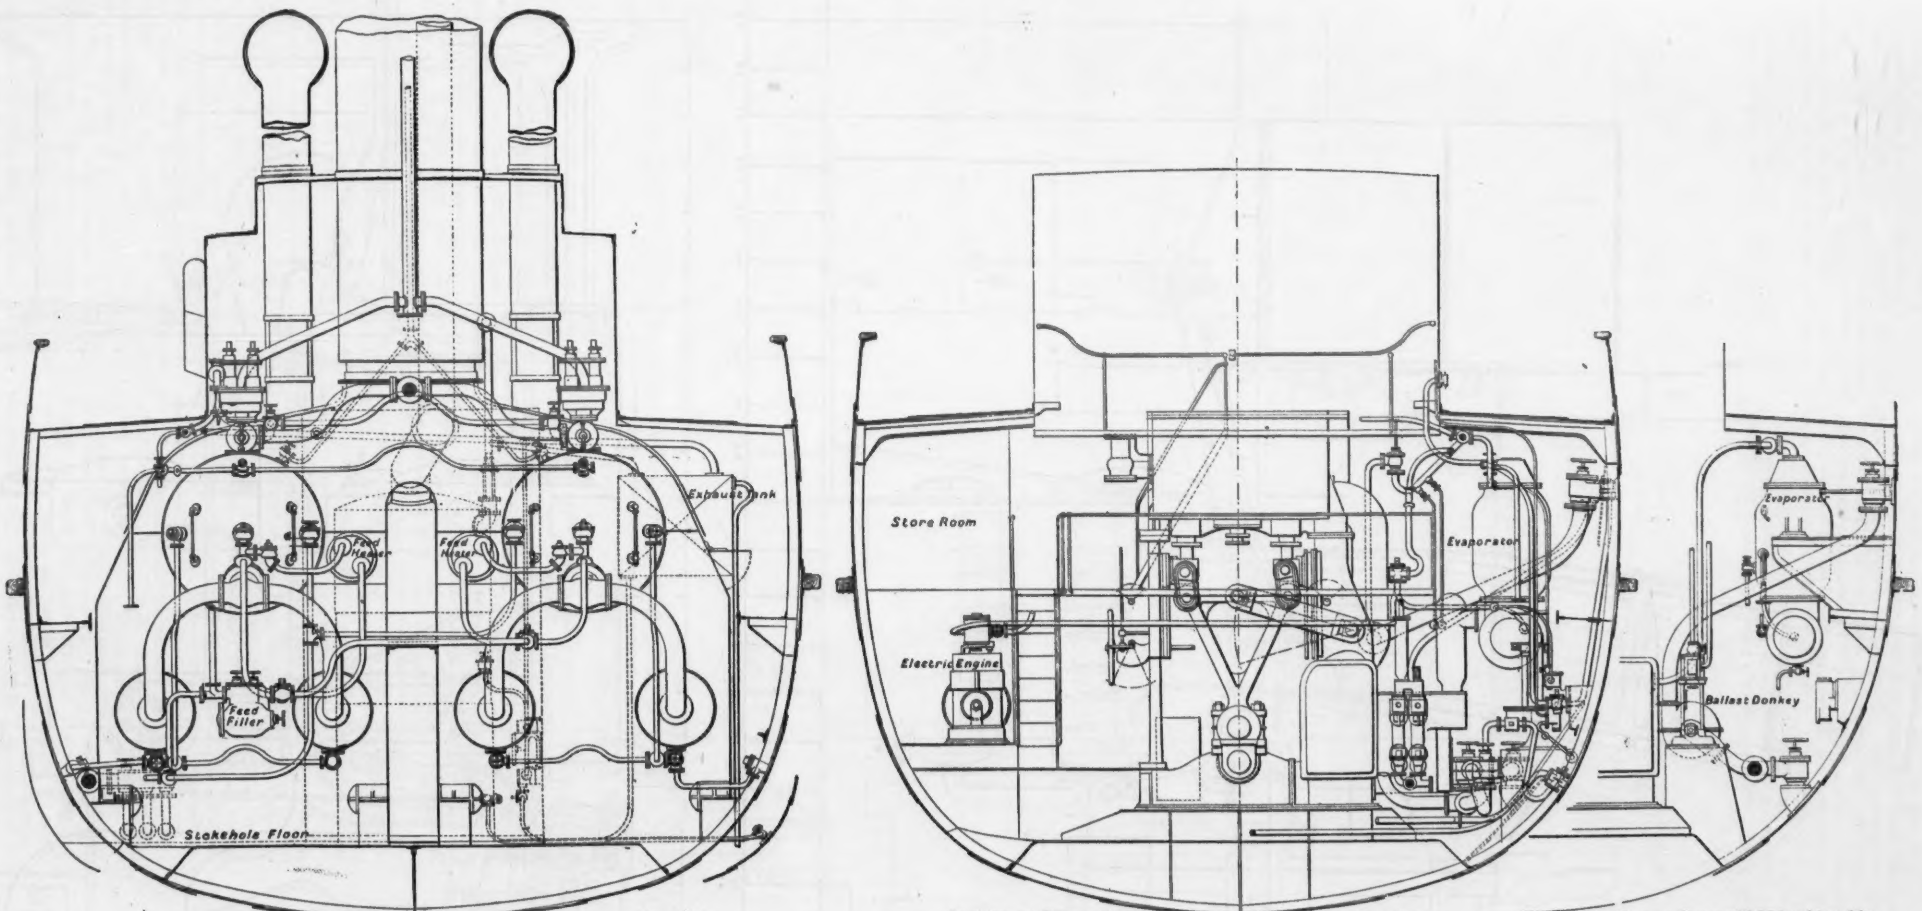
Certain steamship owners have successfully broken through this close combination by carrying traffic between Irish and English ports at greatly reduced rates; but although this has been a great advantage to the traders at the ports directly served by the opposition steamers, it has been of little benefit to the inland trader, who is denied the opportunity of participating in the advantages of the lower rate of sea carriage because the railway companies have charged their local rates to and from the ports instead of the cut rates which the steamers in the conference enjoy. The railway companies have declined to place the through rate arrangements in operation *viâ* Manchester, and consequently steamship owners in the conference who would otherwise use the Manchester Ship Canal are debarred from doing so by their conference arrangements. Some of the opposition steamship owners who are not bound by the conference terms have now, we understand, made arrangements to run to Manchester with a view of at once serving Manchester and the immediate district, and, with the help of the Manchester Ship Canal Company, of obtaining through the Railway Commissioners the advantages of through rate arrangements to and from interior towns in England and Ireland.

The new services will commence early in April, the sailings being between Manchester and Belfast twice weekly; between Manchester and Dublin twice weekly; and between Cork and Waterford and Manchester commencing with a weekly service. The Belfast line will be run by the Belfast and Mersey Steamship Company, Limited, and the Dublin and Manchester service by the Dublin and Mersey Steamship Company, Limited. It is not yet announced what steamship companies are to undertake the Cork and Waterford services.

We understand that the rates of freight which will be charged by the new services will even at the outset be much lower than the rates charged by the conference steamers.

ENGINES AND WATER-TUBE BOILERS, S.S. ABERDEEN

MESSRS. FLEMING AND FERGUSON, PAISLEY, ENGINEERS



Section at Frame Nº 34 Looking Forward

Section at Frame Nº 32 Looking Aft

Section at Frame Nº 29 Looking Aft

ENGINES AND BOILERS OF THE S.S. ABERDEEN.

WE give sectional illustrations of engine and boiler space of the s.s. Aberdeen, built by Messrs. Fleming and Ferguson, Paisley, for the Government of Canada, and intended for service on the East Coast of the Dominion. In the equipment of the Aberdeen, the Government have adopted the very latest developments in marine engineering and boiler-making practice. Engines of the builders' patent quadruple triangular connecting-rod type have been fitted. Diameter of cylinders, 18in., 28in., and 35in., by 54in.; stroke of piston, 36in.; clearance, top ½in.; clearance, bottom ⅝in.; maximum revolutions per minute, 96; indicated horse-power, with natural draught, 1510.

Steam is supplied by two of Messrs. Fleming and Ferguson's patent Clyde water-tube boilers, constructed for a working pressure of 220 lb. The diameter of tubes is 2½in. outside. The heating surface in each boiler is 1412 square feet. The grate area in each boiler is 50 square feet. The weight of one boiler complete without water is 27 tons 13 cwt. 3 qr. The weight of one boiler complete with water is 35 tons 14 cwt. 1 qr. With these boilers an evaporative efficiency of 10 lb. of water per hour per pound of coal is obtained, we are informed, with natural draught. They are especially suitable for large powers, it being possible to take as great or even greater powers than has been the practice with the cylindrical boiler, and they also obviate the sub-division of large power into a great number of boilers with their numerous fittings and details. The size of tubes is not reduced to a diameter that makes them liable to be choked, but is kept of a diameter which enables them to be readily cleaned. The drums are of a size that allows of a good supply of water always being in boilers, as well as an ample steam space, doing away with all liability to prime, and at the same time making regularity of water level a certainty. The whole of the inside of the boiler can be easily examined by taking off the ordinary manhole doors, no special jointed doors or caps being required to get inside to the tubes. There are no landings or joints in the fire, and no liability to leakage through expansion strains. In the event of any tube requiring renewal, it can be drawn into the upper drum and replaced in the same way without cutting out any of the other tubes or parts of casing. The manufacturers say they are not the lightest possible water-tube boiler, nor have they the greatest amount of heating surface, but they are fit to stand the every day wear and tear of constant service.

The s.s. Aberdeen is 187ft. by 31ft. by 19ft. 3in. She has been constructed to the highest class at Lloyd's, and to the requirements of the Imperial Board of Trade and Steamship Inspection Act of Canada, for the Government fisheries protection, buoy service, and lighthouse supply. The vessel has a straight stem, is fore and aft rigged, and flush-decked with large bridge amidships, under which is fitted a steering and chart-house, and on the bridge a large pilot house. A steel house aft is fitted with accommodation for the Inspector of Fisheries and Lighthouses, consisting of a large stateroom, chart-room, bath-room, lavatory, &c., and the entrance to the main saloon and officers' accommodation, which are below deck, is also in this deck-house; the accommodation for petty officers and crew is forward. The vessel is fitted throughout with the electric light, and is also supplied with a very powerful search light of Admiralty pattern to assist her in the special service for which she is designed. She has a double bottom fore and aft, divided both longitudinally and transversely, to give her extra stability when lifting large buoys, and is fitted with a very powerful steam winch and derrick to assist her in this work, and has also extra strong towing gear for salvage operations. The vessel is fitted with steam steering gear both midship and aft, a steam windlass, steam heating apparatus, and a very complete outfit of stores.

RAILWAYS AND THE COUNTRY.—While railways formed an inconsiderable item in the mass of private enterprises, while their effects on the internal traffic and intercourse of the country were partial and limited, their concerns could hardly escape being treated as the speculations of individuals, or at most as objects of a separate interest, which might be favoured or discouraged, according to the point of view from whence they were approached. As soon as their practicability was discovered, and the profits to be drawn from them became known, a kind of antagonism began to prevail; as if the nation, on one hand, and the railway capitalists on the other, were natural opponents—so that for some years, even down to the close of 1844, a notion of this implied hostility might be traced through all the public transactions on this subject. The labours of Mr. Gladstone's notable committee, and the creation of its unlucky and short-lived offspring, the special "Department of the Board of Trade," are late and prominent instances of this manner of viewing railway business. While such ideas prevailed, it was next to impossible to handle it in a comprehensive manner or a considerate temper. When the prosperity and safety of the country require that its roads shall be well and cheaply made; when the welfare of three-fourths of those who have money in the country is now directly concerned, that the hundreds of millions spent on those roads shall be fruitfully returned to them, the other fourth having an indirect interest, nearly as strong, in their success, it is high time to treat all questions which regard so important a branch of national industry, and so vast an amount of the national wealth, on the distinct ground that there can be no railway as distinguished from a public interest. What is good for the railways is good for the empire, and *vice versâ*. Hitherto the assumption has been that one could only be served by what it was able to extort from the other.—*Railway News.*

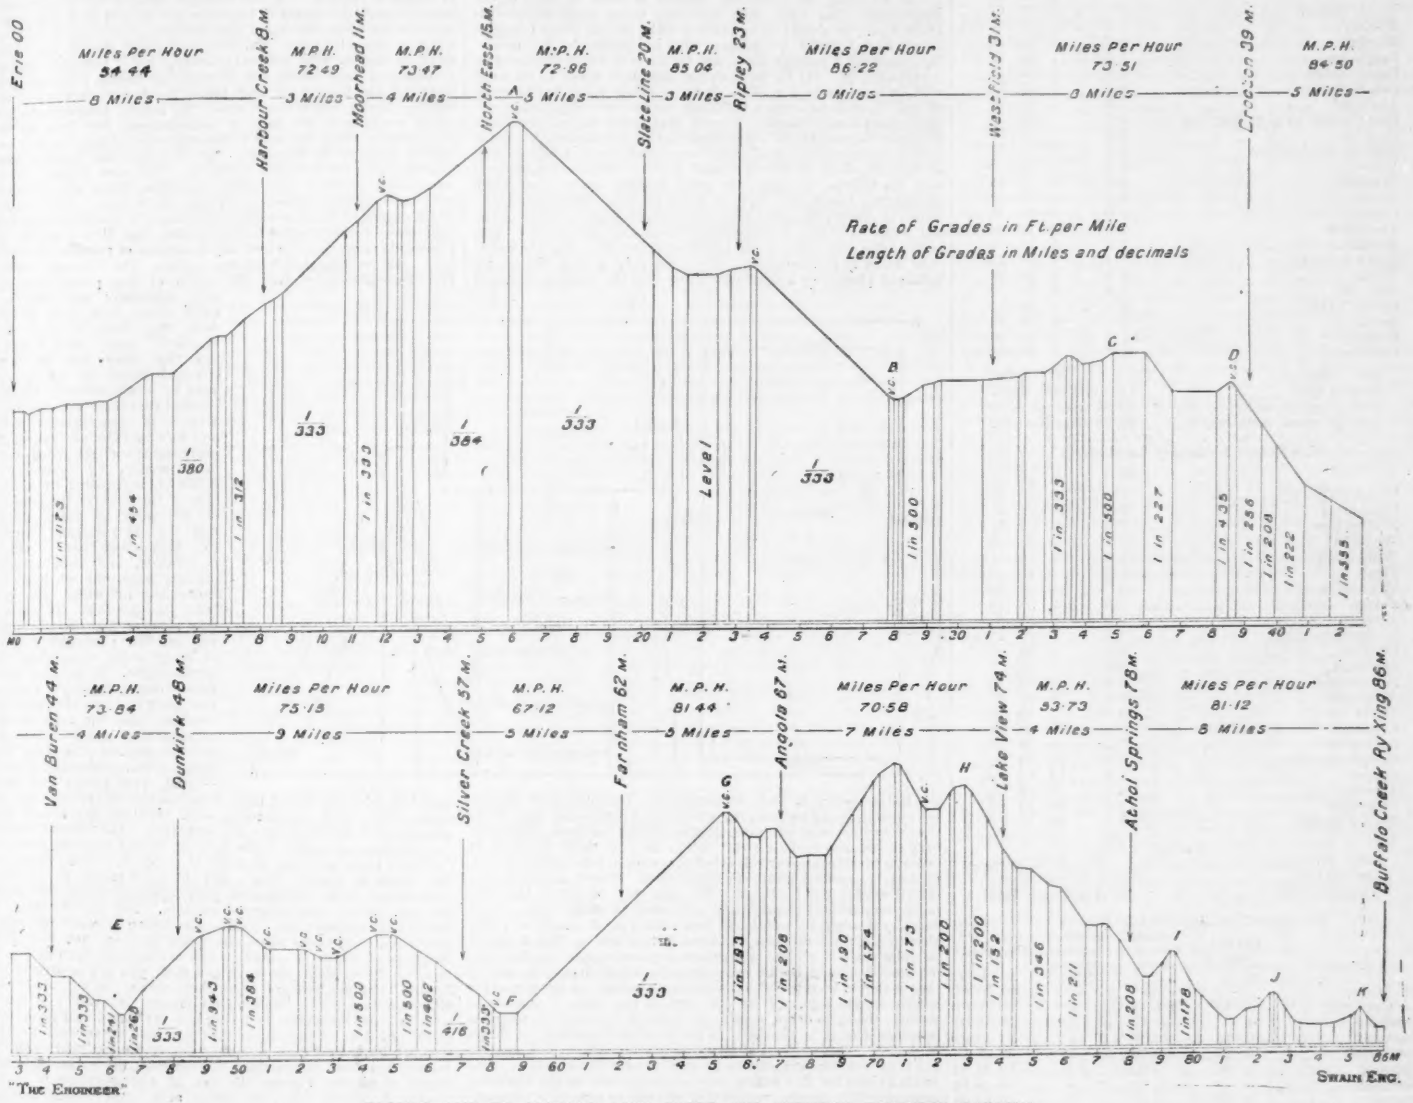
DETAILS OF THE FAST RUN ON AN AMERICAN RAILWAY.

THE wonderfully fast run made on the Lake Shore and Michigan Southern Railway in October last, which was described in THE ENGINEER of November 15th, has called forth considerable discussion as to the records of speed, and the conditions of the run, and we present herewith more detailed particulars than heretofore given. It will be remembered that the train made the run of 510 miles from Chicago to Buffalo in 7 h. 50 min. 20 sec., excluding four regular stops and one flag stop, or at the average rate of 65·07 miles per hour for the entire distance. The train consisted of three cars, weighing in all about 180 gross or English tons behind the tender.



PROFILE—ERIE TO BUFFALO—LAKE SHORE AND MICHIGAN SOUTHERN RAILWAY

The fastest running was done on the last stage of the run, from Erie to Buffalo, 86 miles, and in view of the discussion as to the records, our American correspondent has obtained from Mr. Hardy, the chief engineer of the Lake Shore and Michigan Southern Railway, the profile or longitudinal section of this division, which we reproduce herewith. On the base line are marked the distances, measured from Erie, and above are marked the stations and the distances between them. From the official records our correspondent has calculated the speeds between stations and marked them on the profile, and has also marked some of the principal grades by the system of notation more commonly used in English practice. No stops were made anywhere on the division. Grades marked "V. G." are variable, the changes being too small to be shown on the scale of the drawing.

The conditions of the run are summarised by our correspondent as follows:—Starting from Erie there is an almost continual ascent for sixteen miles—to the point marked A on the section—the greater part of the grades being from 1 in 312 to 1 in 384. Then there is an almost continuous descent for twelve miles to B, consisting of two grades of 1 in 333, each about 4½ miles long, separated by short easier grades. Then there are seven miles to C of comparatively easy ascent, with short grades of 1 in 500 and 1 in 333, broken by a short descending grade. Then come the two level stretches of a mile and a mile and a-half, separated by a down grade of 1 in 227 for one mile and followed by a little up grade to the summit D, 38½ miles from the starting point. Then come eight miles of descent to E, with grades of 1 in 208 to 1 in 333. The next 11½ miles to F comprise a long ascent, a depression, and then a long descent, the maximum grades being 1 in 333 to 1 in 500. This is followed by an up grade of 6½ miles long, 1 in 333, to G. Here commences a stretch of eight miles of broken grades, up hill and down dale, the maximum grades being from 1 in 173 to 1 in 208. This brings us to the summit H, whence there is a steady fall to Buffalo, with the sharpest grades 1 in 152 to 1 in 346. The descent is broken by easier grades, short level stretches, and three easy ascents to the summits I, J, and K.

We are also able to give herewith the official figures of the "log" of the entire run, the figures for the last part of the run being supplemented by the speed between stations, and our correspondent, who has calculated these out, states that they check very closely with the official figures for the average speed over the division. In regard to doubts which have been expressed as to the accuracy of the record, it is stated that the figures given by local papers of the towns through which the train passed tallied closely with the official figures of the train sheet, while the times of starting and finish recorded by reporters for the Chicago and Buffalo papers respectively form another check upon the actual running time. It has been assumed that the time was taken only in minutes, but this, we are told, is entirely erroneous, as shown below. There were four timekeepers, working two at a time, each holding a stop watch. The superintendent of each division called out the names of the stations as the train passed, and a fourth man took down the figures called off by the timekeepers. All the men are well known in railway and professional circles, and any talk of collusion or false figures would be absurd, while the official record was sent out over the signature of Mr. Canniff, the general superintendent of the railway, who was in the train.

The engines used on the first four divisions of the run were of the eight-wheel type—illustrated in THE ENGINEER of November 15th, 1895—having four driving wheels of 6ft. diameter, and a four-wheeled leading truck or bogie. On the last division, however, an engine of the ten-wheel type was used, having six driving wheels 5ft. 6in. diameter, and a four-wheeled leading truck. It had cylinders 17in. × 24in., and ample boiler and fire-box capacity. It weighed 113,500 lb., with 88,500 lb. on the driving wheels. One reason for using this engine was that it had a tender of greater tank capacity than the tenders of the other engines. The others carried 3100 gallons, and this one 3700 gallons of water, and the tank was practically empty at the end of the run. Each tender carried six tons of coal. This tender weighed loaded 88,500 lb., and the others 80,000 lb. The maximum speed was one mile at the rate of 92·3 miles per hour, and the average speed was 72·91 miles per hour for the 86 miles. The revolutions were 469 and 371 per minute, and the piston speeds 1878ft. and 1484ft. per minute for the maximum and average speeds respectively. The coal consumption was 3250 lb., equivalent to 37·79 lb. per mile, 2788 lb. per hour, and 100 lb. per square foot of grate per hour. The water evaporated was 30,833 lb.—3700 gallons—or 9·48 lb. of water per pound of coal. Of course this engine, not being designed or intended for such maximum long-continued speeds, could not be expected to be economical; nor was it wanted to be so, since the sole aim was to see in how short a time the run could be made. One of the eight-wheel engines—with four driving-wheels 7ft. diameter—which haul the Empire State Express of the New York Central Railway, has, our correspondent states, a month's record in 1894 averaging 32·38 lb. of coal per mile, the average speed of the train being 50·7 miles per hour at that time.

Engines with six driving-wheels are very largely used in the United Seates for heavy express trains, and are usually of the ten-wheel type, having a four-wheeled truck or bogie. Some roads, however, use the Mogul type, having a two-wheeled truck; and an engine of this latter type, used for mail and express trains on the Chicago, Burlington, and Quincy Railway, has records of 22½ miles in 21 minutes and 15 miles in 13 minutes, with a train of four cars in each case. This engine has cylinders 19in. by 24in., driving-wheels 5ft. 8in. diameter, truck wheels 3ft. 1in. diameter, and weighs 120,000 lb., of which 101,000 lb. are on the driving-wheels. Our correspondent knows of a six-wheeled switching or shunting engine with six coupled wheels 4ft. 2in. diameter, having been run at a speed of 45 miles per hour. The following is the complete "log" of the run, which was made on October 24th, 1895:—

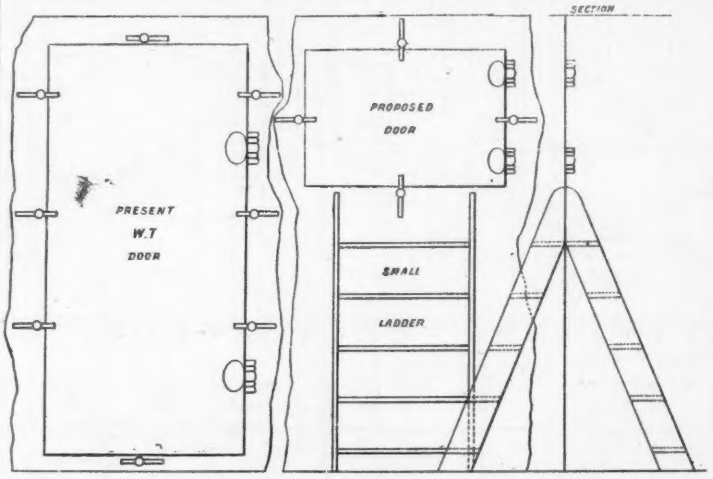
WATER-TIGHT DOORS, AND THEIR DANGER TO MODERN FIGHTING SHIPS.*

By Captain the Right Hon. LORD CHARLES BERESFORD, C.B., R.N.

IT appears to me that every effort has been made, as far as human ingenuity has gone at present, to secure a ship floating after a severe gun action, but equal attention has not, in my opinion, been paid to this consideration in the event of a ship being badly wounded by ram or torpedo. It is to reduce the probability of losing a vessel through the agency of these "elements" that I make the following proposals. A battleship is a variety of compromises, and water-tight doors form one of those compromises. The water-tight door compromise may be defined in the following manner:—It is the safety of the ship *v.* the convenience of the departments. In my opinion the safety of the whole ship is infinitely more important than the convenience of the different departments. According to the system which obtains at present we put ourselves to great trouble, inconvenience, and expense, and add enormously to the weight of our ships—a most material point—by building a large number of bulkheads athwartships, and fore and aft, to ensure her safety when wounded below the water-line. Then, in order to defeat our original object, we cut a great hole—often two—in each bulkhead for the convenience of the different departments on board, and so practically re-convert the ship into one compartment. It has so often been proved that the holes are invariably open when an unforeseen contingency occurs.

I propose to avoid the danger of that possibility by (1) doing away altogether with the greater number of the doors, and (2) by so modifying the size and position in bulkhead of some of those which remain as to prevent a sudden rush of water being immediately distributed through different compartments in the ship, as occurred in the Victoria. The total number of doors in each of the following ships is:—Magnificent, with 150 compartments, 208 doors; Royal Sovereign and Repulse, 187 compartments with 148 doors; Rodney and Anson, 121 compartments and 98 doors; Theseus and Hawke, 122 compartments and 98 doors; and the Agincourt, 29 compartments and 17 doors. The old ships have few compartments, but much less doors in proportion.

The following list gives the number of doors in ships of the Magnificent class dealt with according to my suggestions:—(1) Doors I propose should be done away with, 19; (2) doors I suggest should be modified in accordance with my proposals, 23; excepting ammunition passage doors, and (3) doors in which no alteration is proposed, 22. (1) By far the most important doors to do away with, in my opinion, are all on all decks below water-line between 63 and 105 stations—which bulkheads enclose the engine-room and boiler-room compartments. I agree that quick communication is necessary between the engineer officer and his subordinates, but quick verbal communication is all that is required; and, in my opinion, all demands could be met by a small scuttle. These compartments form the belly of the ship—the great floating power from which she gets her buoyancy. In case of one of them being flooded with water, or filled with steam from a fractured pipe, or other cause, the water or steam is immediately communicated to the whole belly of the ship owing to the impracticability of closing the water-tight doors in an emergency. Now, not only is each thwartship bulkhead pierced by a door—often two—but the midship bulkhead also has often two in each compartment. The next most important place is, in my opinion, right forward, where water-tight doors should be done away with altogether in collision bulkhead, and I think they should also be done away with in the next bulkhead abaft, in order to be still comparatively safe if the collision bulkhead gives way. In fact, no opening whatever, either sluice valve or anything else, should exist in this bulkhead. The only way to get to the foremost compartment should be by a manhole in deck above. Incidentally it might be mentioned that I think (*a*) it would be advisable to shift the collision bulkhead further aft, so that it should be quite clear of all the strengthening pieces supporting the ram; (*b*) that it should be far more strongly fitted than it is; and (*c*) that it should be rounded like a barbette instead of being at right angles to the side. (2) In the case of the doors I propose to modify, the large doors should be replaced by small rectangular openings close up to the deck, at the top of the bulkhead, as shown in sketch. This proposal is intended to allow officers and men to get from one compartment to another quickly if necessary. The merit I claim for this fitting may be exemplified in the following manner:—If a ship be wounded by torpedo or ram in a compartment below the water-line, the water will rush in with irresistible violence. With the present system of water-tight doors, where the sill is nearly level with the deck, there is nothing to prevent the water rushing to all parts of the ship at once, and it becomes impossible to close the doors. With my proposal the water meets a solid bulkhead all round the compartment to a height of five, six, or more feet, according to the height of compartments. The water is confined for some appreciable time in one space, and this gives ample time to close and secure the rectangular opening at the top of the bulkhead.



There are only seven doors in the whole ship below the water line that, in my opinion, should remain. The doors that are necessary should, I think, be improved. I cannot conceive a worse principle than is employed for closing the hinged doors in the British Navy. The hanks and butterfly nuts have each one to be secured or screwed up separately. The consequence is that in a panic or sudden emergency you invite an accident, as it is unlikely that men will remain to secure each hank and each butterfly nut, without which the door cannot be effective. I have seen many doors, a great deal better than the ones employed in the Navy, of the same weight and about the same price. The principle that should be enforced is that it should be possible to shut the door and secure it in one movement. Owing to the length of my paper, I do not propose to enter into details concerning the doors of the other classes of ships I have named; but I am most strongly of opinion that in fighting ships of all classes the suggestions I have made should be carried out in each ship building, and that ships built should be altered in the direction I advocate. It is only by using foresight that possible, and I consider probable, dangers may be avoided.

Summary.—The summary of my contentions is:—(1) Many water-tight doors can be abolished. This would add to the safety of the ship. (2) Many water-tight doors can be modified with the same advantage. (3) That where water-tight doors are necessary of their present size, they should be constructed on a better principle than those we now use. (4) That all these alterations in construction can be carried out without affecting the fighting efficiency of the ship.

My object in writing this paper is to invite discussion from those shipbuilding experts who are best able, by argument, to prove that those who agree with me on this all-important question are right or wrong.

TRADE AND BUSINESS ANNOUNCEMENT.—Messrs. W. P. Thompson and Co., Patent Agents, have removed to 322, High Holborn, from 31, High Holborn.

LEGAL INTELLIGENCE.

ROYAL COURTS OF JUSTICE.

March 10th to 20th, 1896.

(*Before* MR. JUSTICE WILLS.)

THE INCANDESCENT GAS LIGHT COMPANY (LIMITED) *v.* THE DE MARE INCANDESCENT GAS LIGHT SYSTEM (LIMITED) AND OTHERS.

THIS was an action brought by the Incandescent Gas Light Company (Limited) against the defendants, claiming an injunction restraining the defendants, their servants and agents, from infringing the plaintiffs' letters patent, No. 15,286, of 1885. The trial commenced on the 9th inst., and was continued on the 10th, 11th, 12th, 13th, 16th, 17th, 19th, and 20th.

Mr. Moulton, Q.C., Mr. Terrell, Q.C., Mr. A. J. Walter, and Mr. J. H. Gray appeared for the plaintiffs; Mr. Bousfield, Q.C., Mr. Roger Wallace, Q.C., Mr. C. E. E. Jenkins, and Mr. W. Neill for the defendants.

Mr. MOULTON, Q.C., in opening the case for the plaintiffs, said that the invention was one of those great inventions which for ever change the work of the world in the particular department to which it referred. It had changed entirely the direction and the success of the efforts of inventors and the practical user in the world in the whole domain of the chemical production of light by means of incandescence. Dr. Welsbach found that if you take a fabric of organic fibre, preferably cotton, and if you steep that in a solution of some soluble salt of refractory earths, you could get, when you had burned off that fabric, a coherent skeleton of refractory oxides, which would stand the fiercest temperatures and which would give out light by incandescence free from all the objections to which the earlier attempts were subject, but that was not the whole of the invention. Dr. Welsbach was working upon that strange class of bodies known as "the rare earths." They were a class found in very small quantities, found always allied with one another—always in groups, as it were. The mineral which contained the one would contain some or all of the others, and they were so closely allied to one another that it was almost impossible in many cases to find any difference of property by which they could be separated from one another. Dr. Welsbach for the first time discovered that the oxides of this group were not only splendidly refractory and could stand heat just in the same way that zirconia and magnesia and lime could, but that they had a most splendid power of giving out light by incandescence. He discovered that these were the finest sources of incandescent light, and he found the way you would best obtain your light-giving structure—namely, by saturating a fabric of, say, cotton by a solution of the salts of these metals or the salts of these metals and the old refractory earths, so that they were purely in solution, and then actually burning away the whole of the scaffolding by which you had built your erection. It was the only rival of the electric light, and on the Continent it had in many cases vanquished the electric light. It was also enormously used in England. Three or four times the amount of light was obtained from the same amount of gas as that obtained from the ordinary method of lighting. The reason of the success was as follows:—Using what people had never used before—a solution of some of the soluble salts of these and the other metals, such as zirconium—Dr. Welsbach got a fluid that penetrated everywhere into the structure. The learned counsel described the operation of the solution in the following terms:—"Where there are cells or pores it comes in; where there are fine fibres it encases them; and the consequence is you have everywhere, in the intricacies of your organic structure with which you are dealing, your pregnant solution. You dry it—these, of course are eminently non-volatile—the drying drives off the water, and there, everywhere where the water has been, you have your fine layer of nitrate or acetate, which are the salts that he recommends. Now, when you have got that, you are apparently no further; but you have got everywhere where you will want your structure that which by the next process you will turn into a coherent hard structure, following in every detail this layer, if I might put it so, of the nitrate that you have so successfully laid. You set fire to that when it is dry; the cotton, or whatever it be, burns; the heat of burning, dealing with the exceedingly fine layers of nitrate, exposes the salt to a temperature it cannot bear; it drives off the nitric acid, and leaves nothing but the oxide of the metal. It leaves it in a coherent form, and you get casts of every single fibril that has been twisted together in order to form the thread that made the fabric. You have got, as it were, a cast of the whole organic structure of this body; and in what form is that cast? It is a cast in which all the detail is found. The consequence is that you have in many places, probably throughout the bulk of the mass, fibrils of cellulose represented by their facsimiles in these coherent oxides, and now you expose it to a great temperature, and we know the strain that a great temperature is on all these bodies. It produces an expansion, and the cessation of the flame produces an irresistible contraction of what is no longer a solid body, where you might get fracture, but of a body built up of these fine casts of fine filaments; and it is found that you can make this and you can burn it for hours—these will last 800 and 1000 hours in some cases. You can turn it out; the shrinkage and expansion and all that is in a body built up of fibrils so small that they have an elasticity, however fragile, as it were, the material of which they are made. As far as we can make out that is the meaning of the success, and that condition of making our mantle by means of a solution of these soluble salts of the refractory metals and earths and burning them into oxides after they have soaked through and penetrated into every part of the organic structure is the essential of every successful incandescent burner of the present day. Further, an essential of it is that you use wholly or partially, either to the greater or less extent as fancy may please, these rare earths." Dr. Auer von Welsbach was dealing with the practical problem. At the date at which his invention came out these earths were known in their casual conglomerate existence as the oxides to be found in these rare minerals. They were separated only as a chemical *tour de force.* This was a practical invention. The proportions did not matter. This was not a thing in which proportions did more than give a better or a worse result—not a different one. In this great strain to which these materials were exposed, it seemed to be like soldiers under a hot fire, each man had got to stand steady, and in this patent Dr. Welsbach plainly said that any of these rare oxides with one exception—and he branded the coward—could stand the strain. Of course, when this became not a question merely of theoretical chemistry, but a great practical industry, people threw their whole force into the study of these rare earths. The sources of them were locked up. At one time it looked as though the manufacture of these mantles would exhaust the little amount of these earths to be found on our globe. Well, people now, finding that they were things of use, and things therefore of value, set out and found other sources of supply. Instead of leaving them as mere mixtures, they separated them and divided them up, and sometimes you might use for one kind of light a preponderance of one form of oxide; for another a preponderance of another. It was immaterial what mixture was chosen. Dr. Welsbach taught that all these could be used, and if the defendants chose to make subsidiary inventions by emphasising one ingredient or emphasising another it did not matter. The characteristics which would be found always in the successful incandescent—he might even say the existing incandescent—light were those two of the organic structure initiated in these hard coherent refractory oxides; and the source of those oxides, where they did not come from the whole refractory earths, was to be found in this group of strange metals which the plaintiffs were the first to use. That was the invention. Now, what had the defendants done? They were a company that had threatened to make and sell an appliance which was an infringement. Instead of taking a hood they had taken the individual threads forming a fringe. Dr. Auer von Welsbach said in his specification, "Obviously fabrics of various forms or construction may be employed according to the character of the burner to which they are applied." The defendants' fringe was applied to a bat's wing burner or flat-flame burner, and the burner played on those impregnated threads. The defendants merely changed the form. They could not change the real substance of it. You must have your thread, you must have it impregnated; you must have it impregnated with something in solution, and that something must be a soluble salt of one of these resistent earths; and if you were going to have any success at all it must include one of these rare oxides that you found in ytterite and cerite earth. When you had got that you might vary your shape as you liked. Varying the form or varying the predominance of any particular one of these almost indistinguishable substances in the actual mantles used had not taken the infringers out of the ambit of the specification; but, to use the language consecrated in many of the greatest decisions on patent law, they had taken the pith and marrow of the patentee's invention, and as such they were infringers of the patent.

---

* Abstract of paper read at the thirty-seventh session of the Institution of Naval Architects, March 25th, 1896.

Evidence was then called in support of the plaintiff's case.

Professor James Swinburne said that by no experiments which he had made according to directions given in specifications prior in date to the plaintiff's had he been able to produce a coherent mantle.

Professor James Dewar said that in his opinion the process described in Welsbach's specification was novel. By the substances mentioned in the specification he understood the application of the oxides of the rare metals, or commonly called the oxides of the rare earths. As to the alleged anticipations connected with Frankenstein, the process there described would not make a practical incandescent mantle. The whole fell to pieces almost at once. There was no permanence and no cohesion. None of the alleged anticipations showed that process which was essential to success. If you took the Frankenstein method with the Welsbach materials you could not make a mantle. Looking at the Welsbach specification, in his opinion, the patentee showed that what he used were these rare oxides. In his opinion there was not yet any practical value in isolating for this purpose erbium. This group of rare earths, or the metals which formed the base of the rare earths, were very seldom found separate, and they all more or less contained one another.

Mr. W. Webber, a gas engineer of thirty years' standing and head of the editorial staff of the *Journal of Gas Lighting*, said, as regarded domestic lighting, the incandescent burner had knocked out everything else in the way of improved lighting.

Mr. John Imray said that, in his opinion, Welsbach's invention was this—to take a soluble salt of a number of metals of a peculiar kind, to soak a fabric in that solution, to dry it, to subject it to an ammonia gas, then to burn away the material which had been soaked, leaving the earth oxides standing as a skeleton. In his opinion it was a manufacturing operation—a purely physical operation. At the time of Welsbach's specification the invention was quite novel, and a total departure from anything that had been done before. From a commercial point of view Welsbach's invention was the first one which had ever succeeded in incandescent lighting. In his opinion, if threads of oxides were obtained by saturation, drying, and burning off, it was a method described in Welsbach's specification. Several other experts, including Mr. H. Ballantyne, Mr. W. R. Cooper, Mr. A. A. Beadle, Mr. Dugald Clerk, Mr. A. Pringle, and Professor C. J. Lambert were called in support of the case for the plaintiff.

Mr. Bousfield, Q.C., in opening the case for the defendants, said that the case, although it had taken some time and involved, perhaps, the consideration of somewhat recondite points in some of their aspects, was, nevertheless, about one of the simplest cases for a patent case that could come into Court. He hoped to satisfy his Lordship that the principles of construction to be applied to a specification were absolutely independent of the magnitude or the smallness of the invention. No doubt the magnitude and the importance of the invention, the amount of capital involved in it, and all those things which his learned friend had tried to put forward as to the amount of employment given in allied industries had an effect, or might have an effect, on the mind of the Court, although, strictly speaking, they ought not to be brought in. It was, perhaps, therefore, a little important to observe in this case that the plaintiffs, after all, had only taken the benefit of a long series of prior suggestions in the same department; and although, no doubt, they had been—not the plaintiffs, but Mr. Welsbach—the first to reduce this particular form of mantle to a practical form, yet, after all, the differences between what they had done and what had been done before were not much more than the differences between what they were doing now and what they were doing in 1885. In the patent Mr. Welsbach said that the compound used by him consisted of lanthanum and zirconium, and that you might or might not if you pleased use yttrium with it. He gave you the proportions when you had got the yttrium, and then he told you that if you dispensed with the yttrium you were to have half zirconium and half lanthanum. So far, there was no notion of equivalents about them. There were two necessary elements of his compound, and one optional element of his compound. Then he went on and gave you the two equivalents. He said for yttrium you might have ytterite earth, and for lanthanum you might have a certain kind of cerite earth. In this case the other side had been engaged in compounding those things which the patentee had endeavoured to separate. The defendants stated distinctly that they intended, unless restrained by order of the Court, to make mantles which should contain zirconia and erbia. If the patentee contemplated as a known equivalent at the date of his patent the use of erbia instead of yttria it would have been mentioned in the patent, but it was not put in on purpose, having regard to the fact that he must have known about erbia as well as yttria. There could not be any infringement of this patent without having the two necessary groups represented—the zirconia and lanthanum. These two things, zirconia and lanthanum, or their specific equivalents, being necessary for infringement, the defendants had not infringed, because those were the two essential elements. The yttria group was the non-essential, the optional element. The essential compound described by the patentee consisted of the two things—zirconia and lanthanum, or their equivalents. The defendants had got no equivalents whatever for the lanthanum, which, of course, was the thing which was newly introduced by the plaintiffs for the purpose of incandescence. Zirconia or zirconia and magnesia mixed, whether in complex or fine threads, were well-known incandescent bodies. That which the patentee put ultimately was a compound of the well-known zirconia used for that purpose with lanthanum, to which might be added yttria or its equivalent. Instead of having that compound—those two elements which represented the essential features of this compound—the defendants had only got zirconia, and they had no equivalent whatever for the cerite group; it was their intention to use simply erbium, which, of course, was not in that group at all. It was not one of the cerite group. It was no doubt one of the yttria group, but it was a thing as well known as yttria at the time of the patent, and if he had intended that erbia should have been an equivalent for yttria, he would most surely have mentioned it, because he knew most perfectly well of erbia and knew actually at the date when he filed that complete specification that erbia would do because he had mentioned it in a document of even date. He knew that erbia would do. He had discovered it already. But he knew that it would give a green light, and so he failed to put it in that specification and put it in another specification which he filed on the same date, or rather two days before he filed the complete specification of this patent, and it was therefore submitted that, looking at the facts, there would not be an infringement. In the present specification the claim was limited in two ways. What was claimed in the specification was "the manufacture substantially as herein described of an illuminant appliance for gas and other burners consisting of a cap or hood made of fabric impregnated with the substances mentioned and treated as set forth." It was to be "made of fabric." It was only a minor point, but it was submitted that the defendants' cap or hood—if it were a cap or hood, which was somewhat doubtful—was not a fabric at all. It was a fringe. By reference to Murray's Dictionary, or any other standard dictionary, it would be seen that it could not be contended for a moment that a thread was a fabric. Threads were the things out of which you made a fabric. The threads in the defendants' fringe were not knotted together or connected together in any way. There was simply a platinum wire on which were knotted separately all those threads. The defendants' structure had several advantages. One was that it could be turned lower or turned on full. The plaintiffs' must be either full on or it must be out. One of the great advantages of the defendants' particular form was that you could turn it up or down, which made it convenient for many purposes. It would have been easy in this specification if it had been intended to include separate threads to have put in that phrase which was put in a specification of two days before by the same inventor, viz., "instead of using a fabric a number of separate impregnated threads may be used."

Dr. Otto Hehner, past president of the Society of Public Analysts, examined by Mr. Bousfield, Q.C., said that in his opinion the cerite earth mentioned in the Welsbach specification as an equivalent of lanthanum did not contain any substantial proportion of the ytterite group, nor did the ytterite earth mentioned as a substitute for yttrium contain any substantial proportion of the cerite group. There was no indication in this specification that the ytterite group would serve as a substitute for lanthanum, nor at the date of the specification was there any common knowledge of these earths being so employed as mixtures. Nobody with the knowledge of the time would come to the conclusion that lanthanum or its equivalent might be left out altogether. When he first tried to make mantles according to this specification he was not able by following the directions to make a mantle at once without experiment.

Sir Henry Roscoe, examined by Mr. Bousfield, Q.C., said that, taking the knowledge at the date of the Welsbach specification as to these rare earths, that knowledge would not in his opinion have enabled him or a competent chemist to say that other compounds than those mentioned in the specification would serve the purposes which the patentee had in view. There was no indication that the ytterite group, or any member of that group, would serve as a substitute for lanthanum in the patentee's compound. He should not have been able to tell that a mantle made of zirconia and erbia would have the same properties as one made according to the specification.

Cross-examined by Mr. Moulton, Q.C.—Knowledge had greatly advanced since the date of the Welsbach specification. It seemed to him that the general idea of the mantle composed of knitted fibre—vegetable or animal fibre—impregnated with some salt of an earth or earthy material was known before the date of the Welsbach specification.

Re-examined by Mr. Bousfield, Q.C.—There was no doubt that the incandescence and the colour of erbia was well-known to Welsbach, and he did not understand why, if erbia was one of the class of bodies that Welsbach wished to include, he had omitted it.

Dr. A. Dupré, vice-president of the Institute of Chemistry; Professor V. B. Lewes, Professor of Chemistry of the Royal Naval College, Greenwich; and Mr. C. W. Sugg were also called in support of the defendants' case.

Counsel on both sides having addressed his Lordship.

Judgment was reserved.—*Times.*

THE PRIVATE BILLS OF 1896.

While it is satisfactory to have to record that the number of Private Bills promoted in the present session, which are of an engineering character, is greater than that of last year, it is still more satisfactory to note that the money to be spent on the projects they petition for is largely in excess of the sum applied for during the same preceding period. In the category specified are included all the Private Bills relating to railways, canals, tramways, and the supply of gas, electricity, and water. Of such the total number amounts to 157, which compares advantageously with the total of 129 of session 1895. But although the difference in point of absolute enumeration does not surpass 28, the total amount of money proposed to be raised, partly as capital and partly by loan, is not far from twice the amount asked for in the year gone by, the sums being in round numbers as 41 millions and 23 millions respectively. The comparison may be put in another manner. For instance, the average cost of the 129 Bills amount to £171,317, and that of the 157 now before Parliament to £261,593, and as the additional 28 are estimated at 18 millions, each of them runs up to the average high figure of £642,857.

Railways, either as completely new undertakings promoted by independent companies, or as extensions of, and additions to, already existing lines, still continue to head the list of the sessional programme with a grand total of 60, and a length of new line of 810 miles. This statement requires at the present moment a little explanation, which will detract something from the *couleur de rose* which surrounds it. Some secessions from the Private Bill Office have taken place, among which there is one upon a scale of magnitude which must not be passed over. Omitting the smaller fry, to which we shall draw attention on some future occasion, we allude to the defection of the London and South Wales Railway Bill, the promoters of which appear to have recanted before their full profession of faith was accomplished. It is seldom that a project of this magnitude falls through at so very an incipient stage of its parliamentary career. The principal object of the company was to run a new line from Cardiff, through Glamorgan and Gloucestershire, and effect a junction with the Metropolitan Railway Company's Aylesbury Extension line at Great Missenden, Bucks. It was proposed to raise £8,000,000 capital, £6,000,000 by shares, and £2,000,000 by loan, to construct the 164 miles of track. It is only one Bill defunct, it is true, but its decease, at any rate for the present session, reduces the railway mileage to 646 miles, and the total capital of all the projects to 33 millions.

As in former years, the lion's share of the railway undertakings falls to England and Wales, which trebles that pertaining to the land o' the leal. Ireland comes third with the modest quotum of only 40 miles. If we except the recalcitrant project, the remaining railway Bills do not ask individually for very heavy capitals. There are only two which go beyond a million. Of these, one is the Portsmouth, Basingstoke, and Godalming Railway, which proposes to construct 70 miles at a cost of £2,400,000, and the other, the Caledonian, which estimates the expenditure required for 30 miles at £1,650,000. The third place is taken by the Manchester, Sheffield, and Lincolnshire Railway with a request for one million, and the Great Western and the Midland are petitioners for exactly the same sum, viz., £800,000. It may be mentioned that there are four Light Railway Bills, one of which is in Kent, another at Yarmouth, a third at Selby, and the fourth at Bideford, comprising in all 32 miles. The capital needed for them all is estimated at £266,666, or at the rate of £8333 per mile. A somewhat new departure is contemplated by the Cork, Blackrock, and Passage Railway Company, by which it proposes to construct ten miles of new line on a 3ft. gauge, to convert their existing line to the same gauge, and to authorise the Board of Trade to modify or dispense with their usual requirements as to railways. It may be mentioned that £8333 per mile is considerably in excess of the sum light railways are presumed to cost. When the question of Light Railways—Advances—was before the House last week, the estimated expenditure per mile was put at from £3000 to £3500. If they can be constructed at this cost, then the corollary may be accepted that a "light railway is essentially a cheap railway." It is to be noticed that there are no Bills promoted in this session for any new underground railways in the metropolis. There are probably two causes which have contributed to this abstention. One is that railways of this description have not proved so successful as was originally anticipated, and the other that during several recent sessions very important Acts have been passed for the construction of underground lines in London of some pretensions to mileage.

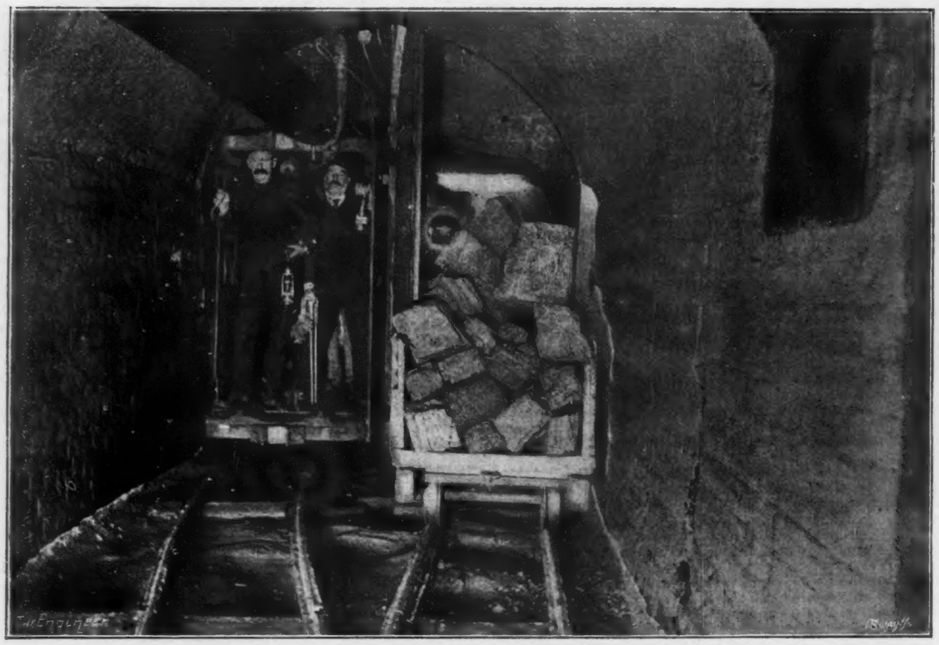
Of Canal Bills there are twenty-nine, which are usually grouped with those we have already categorised, as there is frequently a very common bond of interest between the two classes. As an instance we may select the largest and most important of the inland navigation schemes. It is that of the Bute Docks, Cardiff, which, in addition to its proposal to acquire the canal undertakings of the Glamorganshire and Aberdare Canal Companies, asks for powers to construct 50 miles of new railway, and to raise for its entire project the sum of £1,330,000. Although but a poor competitor in the department of railway extension, Ireland comes fairly to the fore with respect to tramways, quadrupling the contribution of Scotland, and taking £625,000 as her share of the total amount of capital required for the whole of the tramways. The respective mileages for the three countries are, 73 miles for England and Wales, 24 miles for Ireland, and six miles for Scotland. In this class of Bills, Sheffield is far in advance of any other town, as the efforts of two independent companies are directed towards obtaining £900,000 for the development of their two undertakings, part to be allotted to the construction of new lines and part to the substitution of whatever mechanical power may be considered the most advantageous. So far as London is concerned, the Tramway Bills in point of number are about on a par with those for underground railways. One, the London Tramways, seeks to construct about 1¾ miles of double track, chiefly consisting of the doubling of existing lines, for which no capital is asked. The remaining one, the London Council desires merely to run a tram over its proposed new Vauxhall Bridge, so as to join up the present Vauxhall and Victoria line with those on the Surrey side of the river. An important new undertaking is that of the Halifax and District Tramways. Its object is to incorporate a company for the construction of lines, to extend the time for purchase of tramways, and to raise £250,000 as new capital. Swansea, Portsmouth, Blackpool, and Fleetwood, are all investing over £100,000 in the construction or extension of the tramway system.

Under the title of Water Bills a large proportion in reality are Gas and Water Bills. As a Water Bill pure and simple, that of the New River Company heads the list, with a very large margin between it and the next comer. It petitions for further powers for the execution of new works, the purchase of additional lands and for other purposes. Notwithstanding the attack upon the "eight companies," it evidently intends to hold its own, and the couple of millions of capital it proposes to raise will, if needed, help to supply the sinews of war. The Fylde Water Company ask for nearly a third of a million, and the remaining Bills call for no especial notice, if we except that for the incorporation of the Staines Reservoir Joint Committee representing the Grand Junction, West Middlesex, and New River Water Companies. Debenture stock is to be issued to the value of £1,000,000, and the Thames, the Wraysbury, and Colne Brook are to be laid under contribution to furnish a supply. There are only two Gas Bills which can be regarded as of any magnitude, having regard to the fact that we speak of millions now in the same ready and *nonchalant* manner in which we were once accustomed to mention thousands. They are those of the Newcastle-upon-Tyne and Gateshead Gas and the Cheltenham Gas, with respective capitals of half a million and of a fifth of that sum. If we quote the Bournemouth Gas and Water Compound Bill, with its £375,000, it will close the list in this category. Electric lighting projects are nearly all included under Provisional Orders, and the three that figure as Bills belong to one Tramway and two Railway Bills, and are comparatively insignificant as public measures. We shall allude to the Provisional Orders subsequently.

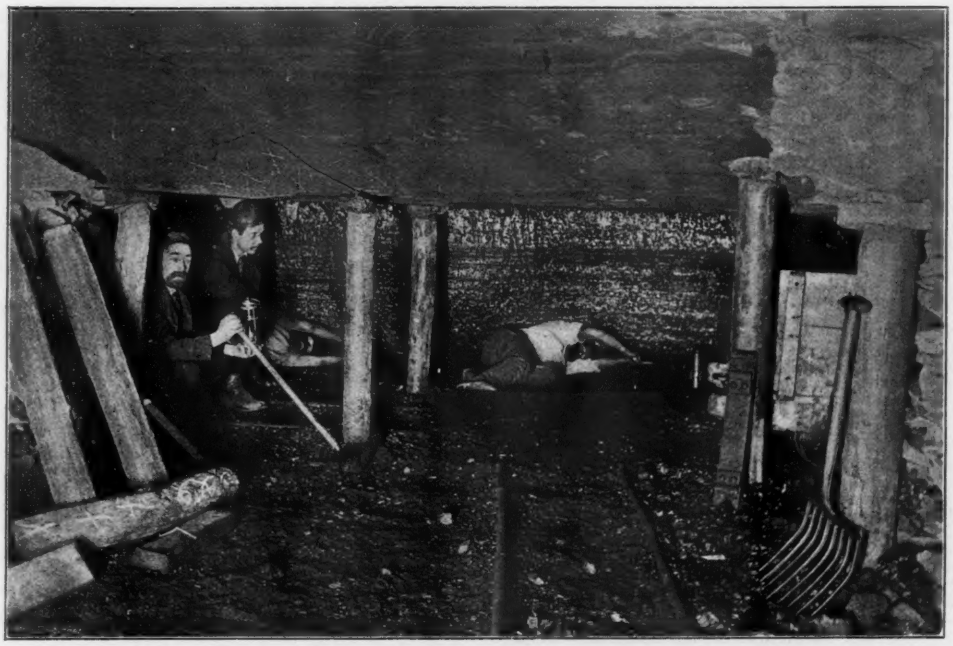
Death of Mr. John Swain, Jun.—We are sorry to have to announce the death, at a comparatively early age, of Mr. John Swain, jun. Mr. Swain has done as much perhaps as any man now alive, to develope the art of newspaper illustration. The pages of The Engineer have borne testimony week by week to his labours. As the active head of one of the largest, if not the largest engraving establishments in the world, it is beyond question that Mr. Swain's zeal and energy induced overwork, with the usual deplorable results to his health.

Death of Mr. Hackford.—We have to announce the death of Mr. George Hackford, F.S.I., of No. 6, Queen Anne's Gate, S.W., which occurred on the 25th inst., at Wandsworth, in the 71st year of his age. Mr. Hackford was born at Boston in Lincolnshire, and early in life entered the office of Messrs. Kirk and Parry, contractors, of Sleaford, and ultimately became their travelling manager. For the last thirty-five years Mr. Hackford, at Queen Anne's Gate, acquired a large practice as a quantity surveyor, very largely in connection with the Great Western Railway Company, and with other railway companies. One of the departments of his business in which Mr. Hackford's loss will be most deeply regretted is the duty of arbitrator, which he so frequently undertook, in all questions relating to contracting disputes. Mr. Hackford's great qualities were, an immense knowledge of all details of cost and construction, the independent position he held, free from all influence, and the unfailing courtesy he gave to all with whom he was brought into contact in business transactions.

VIEWS IN THE PENTRICH COLLIERIES, DERBYSHIRE



HARTINGTON PIT BOTTOM—SURVEYORS ASCENDING



GATE AND COAL FACE UNDER CUTTING

UNDERGROUND PHOTOGRAPHS.

Pentrich Collieries are situated in Derbyshire, near to the village of Pentrich, historically celebrated as the place at which the Pentrich revolution had its origin in 1818. These collieries have been worked by the present proprietor, Mr. W. C. Haslam, and his forefathers, for four generations. The present winding shafts are the Speedwell shaft, which was sunk to a depth of ninety-five yards, in 1841, to work the hard and soft coals, whilst the Hartington shaft was sunk in 1880 to a depth of 160 yards, to work the furnace and Silkstone seams.

Hartington pit bottom.—The photograph above shows the Hartington pit bottom, protected on each side by a brick arch. The cage containing the surveyors is just commencing its upward journey, whilst awaiting the empty cage is a tub of coal, marked with the figure 8, which indicates to the weighmen at surface the name of the men by whom it was cut. Running near the crown of the arch is the steam pipe, which, after leaving the boilers at the surface, traverses the shaft and supplies steam to an underground engine which works the furnace coal haulage plane. Fixed on the right-hand side of the arch, and close to where the onsetter works, is a code of shaft signals, by means of which the onsetter communicates to the engine driver at surface when men or coals are to be raised. On the back of the pit bottom the electric light is shown burning brilliantly in the underground office.

Hartington level—bringing coal to the pit bottom.—Running an angle to the pit bottom is a level along which all coal is brought to the pit bottom; it also serves as a travelling road to and from the workings, and is the principal intake airway. Near the roof is the haulage rope. The assistant onsetter is in the act of lowering the trams towards the pit bottom; behind is the under-manager, whilst in the distance is the tram coupler getting the trams ready for the different districts to which they are going.

Overcast or air crossing.—At a distance of 250 yards from the pit bottom, and forming part of the furnace coal engine plane, is an overcast, which is an arrangement common to most mines, and by which two currents of air are isolated from each other and made to travel in different directions. The intake or pure air travels opposite to the direction in which the men are coming, and after travelling in that direction 650 yards, it is split into two currents, which branch off to the right and left of the engine plane and supply the faces with fresh air. After traversing the faces, these two currents are again united, by one of such currents crossing the overcast, after which they are conveyed to the upcast. The figures shown on one of the bearers indicate when the overcast was last repaired.

Refuge place.—The furnace coal incline continues in a straight line to a distance of 720 yards, and has an average dip of 1 in 7, and, in order to comply with the Act of Parliament, places of refuge are made every ten yards, so that, should anyone be travelling on the plane when the rope is at work, they may find a place of safety near at hand until the train has passed to a safe distance. The man on the front of the drift, which consists of twelve trams, is constantly in charge of the train, and stops or starts the engine by electric signals given from any point in the plane to the driver of the haulage engine. The speed of the train is from six to eight miles per hour.

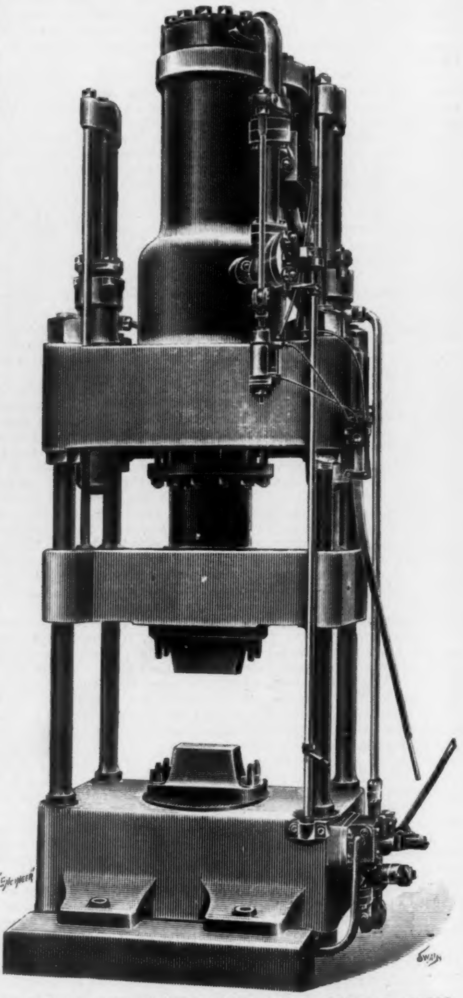
Gate and coal face.—Branching off from the engine plane, the coal face is reached at a distance of 360 yards, and each working place, called a stall, is forty yards long. The thickness of the coal is 3ft. 7in., with excellent roof but very hard floor, which necessitates the holing being done in the coal. Roadways are maintained to each working place, and these are formed by building two walls or packs in a straight line and from 9ft. to 10ft. apart. In order to obtain height for horses and men to travel along, about 3ft. of roof is blown down; such forms a gateway, as shown on photograph, which also shows the tramway along which trams pass to and from the working place. On one side is shown the fork with which the smaller pieces of coal are loaded into the trams. The prop with X marks has been broken by the weight of the roof. Behind the lip of the gateway is the coal face, showing the way in which it is timbered. The two men shown at work under the coal face are "holers," and hole the coal to a depth of 4ft. or 5ft. The working face extends to an equal distance on each side, along which trams are taken to be loaded with coal. One tram is partly shown on the right-hand side. The section of the coal face is clearly shown, and consists of 12in. of very best house coal at the top of the seam, the remaining thickness consists of a second house and steam coal. The X marks on the lip indicate to the workmen a break which needs attention. The manager, Mr. Walker, is on the left, making his daily inspection, carrying with him the most delicate gas testing apparatus in the form of Stokes' alcohol flame lamp.

Speedwell pit bottom.—Speedwell pit was sunk in 1841 to a depth of 95 yards, from which point the hard and soft coal seams are worked. These two coal seams yield excellent qualities of best house coal and best steam coal. The photograph shows the pit bottom, supported by timber, and on the right-hand side are to be seen the electric cables, signal wire, &c. The cage is shown full of men ready to ride to the surface.

For many years the water at Speedwell pit was pumped from the dip workings by a pump worked by a rope, suspended from the roof timbers, but in 1894 this arrangement was found insufficient, and to replace it an electric plant was put down consisting of a dynamo on the surface, a motor, and three-throw pump erected near the bottom of the dip workings, 450 yards to the dip, and discharge through 450 yards of 3in. pipes, with a head of 195ft., 3000 gallons of water per hour. The cables are run down the road. The electric lighting and pumping plant was designed and put to work by Mr. de Grave, engineer to Messrs. J. Davies and Son, of Derby, the photographs we reproduce being taken by the same gentleman, who is an ardent amateur photographer.

HYDRAULIC FORGING PRESS.

The press illustrated by the engraving below, is double-powered, and can be worked at either 100 tons or 200 tons power at will, the change being effected by the simple movement of a lever, so that, upon the same forging, the two powers can be applied, as required when some parts of the forging require less pressure than others, or when it is being finished the low pressure can be used for planishing. It is fitted with a pressure worked main valve, operated with ease by the workmen, who only have a small valve to move. It can be worked up to forty to sixty strokes per minute, the longer strokes being of course fewer, and in inverse proportion to the length.



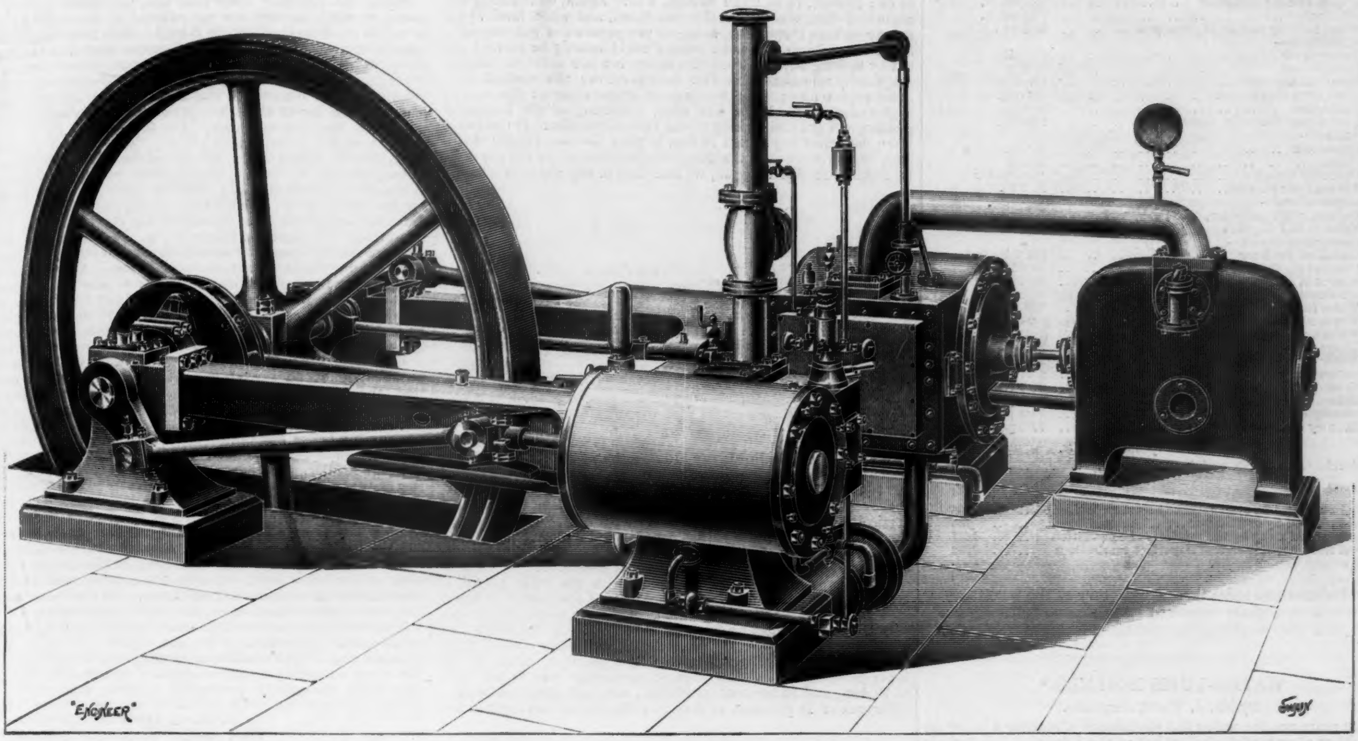
FIELDING AND PLATT'S HYDRAULIC FORGING PRESS

The total stroke of the ram is 30in., the space between the columns 4ft. 9in. by 2ft. 6in., the maximum height between the faces to which the tools are bolted being 4ft. 6in.; it is worked with the standard pressure of 1500 lb. per square inch, but can of course be modified to work at any other pressure. The press, as shown, is also fitted with a cylinder in the bottom table, this being used for some class of stamping work. It can be used not only for stamping purposes, but also for all kinds of work for which steam hammers are generally employed. It is stated by the makers, Messrs. Fielding and Platt, Gloucester, that in the majority of cases these presses will do quite twice as much work at one heat as a steam hammer of anything like equal cost.

The Bombay Municipality is at present considering whether it would be profitable to introduce petroleum automobile traction for meat and rubbish carts.

COMPOUND CONDENSING ENGINE AND MULTITUBULAR BOILER

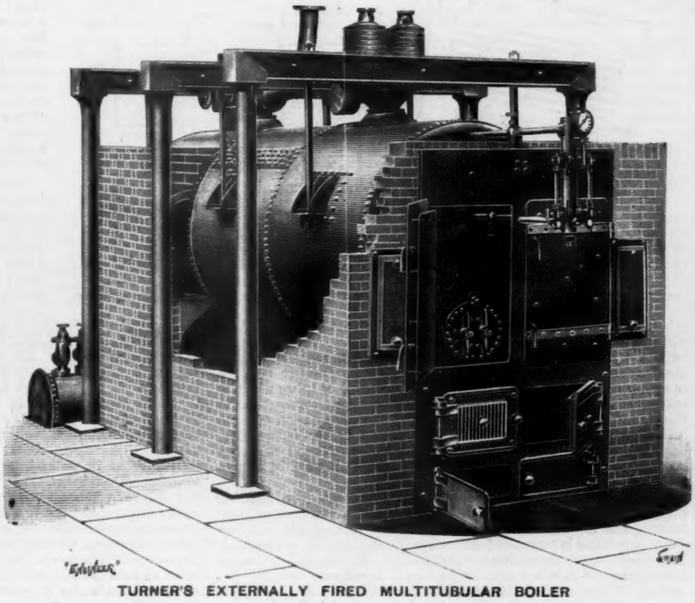
MESSRS. E. R. AND F. TURNER, IPSWICH, ENGINEERS



RECENT AMERICAN LOCOMOTIVE PRACTICE.

It would appear from an article in the *Railroad Gazette* of February 14th that some important discoveries concerning the locomotive engine have lately been made in America. They will not perhaps be considered very novel on this side, having been perfectly well-known, in fact, from periods ranging from twenty to fifty years. All the same, they are rather interesting, as showing that much careful observation is directed to locomotive working, and as confirming results obtained here long ago.

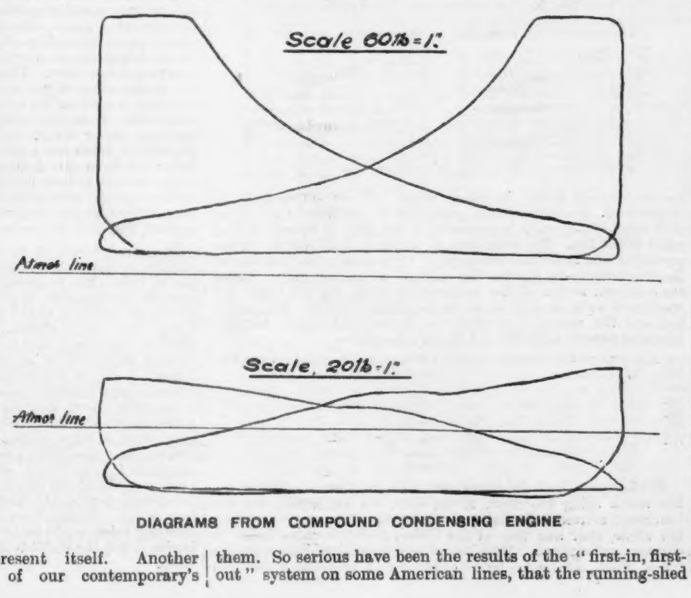
Amongst several other things it seems to have been lately found out that superfluous weight in pistons, crossheads, and other reciprocating parts is decidedly bad, and that it would be a great improvement to make them as light as possible consistent with the necessary strength. Pistons of wrought iron or cast steel, weighing about half as much as the old cast iron ones, are coming into use in America. So long ago as 1852 Mr. J. E. McConnell, then locomotive superintendent of the southern division of the London and North-Western Railway, introduced wrought iron pistons, forged solid with the piston-rod, which for lightness and strength have probably never been surpassed, whilst the steadiness of the engines fitted with them was remarkable, even at speeds closely approaching 80 miles an hour. The evil of heavy reciprocating masses has been found greatest with the very small coupled wheels commonly used under American goods engines. These wheels average probably 4ft. in diameter, and as they have to turn pretty fast to produce the most moderate speed, the action of so much dead weight, in the shape of enormous connecting-rods and counter-balances, is noticed to "take it out" of 70 lb. rails considerably. The English practice of larger wheels for goods traffic is approved by the *Railroad Gazette*, which recommends 5ft. 6in. as a suitable size. On the North-Eastern Railway Mr. Fletcher built a number of six-coupled goods engines with wheels of this size nearly twenty years ago, but the 5ft. goods commonly found in this country are constantly used for fast and heavy excursion traffic, where "Consolidation" or "Mastodon" engines, with a crowd of little wheels, would be virtually useless if the precise kind of traffic they were built for failed to present itself. Another hardly "up-to-date" discovery of our contemporary's is, that the system of giving no drivers or firemen engines of their own, but putting them instead on the first which is ready, leads to their taking no care or thought whatever of the machines. They will do no more small repairs than they can help, naturally feeling that the next set who have the engine may be credited with them if they do, whilst they leave other men to find out defects and get the blame for them. So serious have been the results of the "first-in, first-out" system on some American lines, that the running-shed expenses have increased 11 per cent. under it, whilst the mileage run by the engines between heavy repairs has decreased from 20 per cent. to 24 per cent. The method practised in England from the earliest days of railways, that of giving each driver and fireman an engine of their own, and having a certain proportion of men to take the places of others who may be off their regular turns through illness or injury, is found to be the only really satisfactory way of working.



TURNER'S EXTERNALLY FIRED MULTITUBULAR BOILER

Strange to say, even that venerable British institution, the six-wheeled tender, has been found to possess some merits, especially for express work, where the stoppages are short, and drivers having not too much time to examine their engines, can spare very little for a cumbrous affair with pivots and wearing surfaces right underneath. It is said that some American engineers are afraid of six-wheeled tenders on bad roads, but we can inform them that they very seldom get off the line unless the engine has done so first. In simplicity of construction and facility for inspection or repair, the English tender is far superior to any vehicle of the kind mounted on bogies, and we are not aware that it has been proved to require more pulling than the latter type. The friction of eight wheels, 30in. or 36in. in diameter, as compared with that of six 48in. or 54in. wheels, must quite neutralise any benefits derived from the somewhat more flexible action of the bogies of the American tender.

That single driving-wheels, upon lines sufficiently level for them, are the best for high speeds, is another tardy but recent discovery in America. As we write it is announced that the Philadelphia and Reading Company is so satisfied with the 7ft. single, No. 385, built by the Baldwin Works last year, that it has ordered another just like it. At their present rate of progress our transatlantic cousins will soon know a good deal about locomotives, possibly even to the extent of finding out that it is quite impossible to get 97 miles an hour out of a six-coupled engine.



DIAGRAMS FROM COMPOUND CONDENSING ENGINE

TURNER'S HORIZONTAL CONDENSING ENGINE AND MULTITUBULAR BOILER.

The annexed engravings illustrate a compound horizontal condensing engine and externally-fired multitubular boiler, made by Messrs. E. R. and F. Turner, Ipswich, and working at the battery of the Roodeport United Gold Mining Company, Witwatersrand, where they have been tested with the results we give below by Mr. C. T. Roberts, The engine has cylinders 14·5in. and 26in. diameter and 36in. stroke, and it is fitted with the Turner-Hartnell crank-shaft governor. It is of the girder type, and is fitted with a simple form of injection condenser. The diagrams below are from the engine, taken when the revolutions were 71 per minute, boiler pressure 116 lb., vacuum 19·5in., and barometer 24·2. The mean effective pressure shown in the high-pressure cylinder, 41·8 lb., and indicated horse-power 88·0. The mean pressure in the low-pressure cylinder is 10·4 lb., and the indicated power 70·0. The following figures are from the report mentioned:—Average indicated horse-power, 173·4; water used per horse-power per hour, including that condensed in jackets and lost by radiation between boiler and engine, 18·6 lb.; coal consumption per indicated horse-power per hour—Transvaal coal—3·47 lb.; equivalent consumption in Welsh coal, 2·12 lb.

The construction of the boiler will be gathered from the above engraving, a feature being the method of supporting it so that the brickwork of flues and furnace have none of its weight to carry, and both boiler and brickwork are freed from any of the stresses which arise from restriction of expansion and contraction movements which occur during heating and cooling. In the engraving a portion of the brickwork setting and side flue is broken away to show the method of suspension of the boiler and formation of the flue. The principal dimensions are:—Length, 16ft.; diameter, 6ft.; number of tubes, 64; diameter, 4in. The duration of the test was four hours. The boiler was supplying steam to the engine above described, which was driving seventy stamps, three pumps, two stone breakers, and two sorting trays. A Green's economiser is used for heating the feed-water. The usual rating for a boiler of this size is 100-horse power, *i.e.*, it should be capable of economically evaporating 3000 lb. of water per hour from 100 deg. to 100 lb. pressure.

The total heating surface is	1250 sq. ft.
Grate area	3·75 sq. ft.
Ratio of heating surface to grate area	33·3 to 1
Temperatures—	
External air	65·5 deg.
Boiler-house	84 deg.
Gases leaving boiler	374 deg.
Gases after economiser	236 deg.
Feed-water	70 deg.
Feed-water after economiser	203 deg.
Pressures—	
Barometer	24·2in.
Steam	112 lb.
Chimney draught	·4in. water
Air used per lb. coal	21·7 lb.
Analysis of coal—	
Carbon, ·603; moisture, ·038; ash, ·209	
Value in B.T.U., 9178	
Consumption of coal—	
Coal fired per hour	601·7 lb.
Coal per sq. ft. of grate per hour	16·02 lb.
Weight of clinker and ash produced per cent	30·6
Feed-water—	
Water fed to boiler per hour	3335 lb.
Water evaporated per lb. of coal	5·54 lb.
Water evaporated per lb. of combustible (actual)	7·01 lb.
Water evaporated per sq. ft. of grate per hour	88·8 lb.
Water evaporated per sq. ft. of heating surface	2·6 lb.
Moisture in steam	2·37 per cent.
Efficiency of boiler	61·3 per cent.
Efficiency of economiser	35·5 per cent.
Economy effected by economiser	11·6 per cent.
Efficiency of boiler and economiser combined	73·5 per cent.

Balance Sheet of Heat Units.

Calorific value of 1 lb. coal, T.U.	9178
	9178
Heat expended in evaporating the water, T.U.	5623
Heat utilised by economiser	736
Heat carried away by the products of combustion	1307
Heat lost by radiation and imperfect combustion	1512
	9178

Mr. Roberts concludes that, satisfactory as the results were, they would be slightly improved by using two boilers in place of one, and thus enabling the coal to be burnt more slowly.

WATER-TUBE BOILERS.*

By Mr. J. WATT, Associate.

SOME years ago the writer had the honour of reading a paper on the subject of water-tube boilers before the Liverpool Polytechnic Society, and, after enumerating the points which constituted a good water-tube boiler, deduced therefrom the following rules or laws which should be observed in designing a trustworthy steam generator. They were as follow:—(1) "The tubes should be arranged in a position to absorb the greatest amount of heat, by causing the flame to travel in an upward direction at right angles to their axis. (2) The tubes should be in a horizontal or inclined position, as the most efficient to emit heat. (3) The steam generated should have free and unobstructed escape to the steam receiver. (4) The circulation or supply of water to the tubes must be copious to prevent overheating. These are the theoretical, and form the essential, conditions of an efficient water-tube steam boiler. But, in addition to these, there is another not the less important which concerns the practical part or life of a boiler, viz., the facilities for inspection, cleaning, and repairing."

It is twenty-two years since the above was written, and, although old, it is quite as applicable to day as then, and, as far as the writer's experience goes, quite borne out by practice. There is, perhaps, no water-tube boiler made that will fully come up to all the requirements here laid down, but the nearer we can approach this standard, the more perfect and successful will be the boiler; and by applying this standard to any existing boiler, we are enabled to point out, not only its merits, but also its defects. It is not the writer's intention of going over the whole range of this subject of water-tube boilers, but to lay before you the result of a few experiments, which may elucidate and explain some of the many mysterious circumstances connected with this complex subject.

FIG. 1.

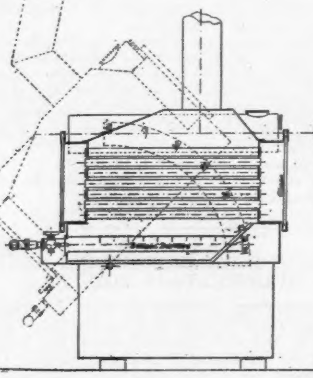


FIG. 2.

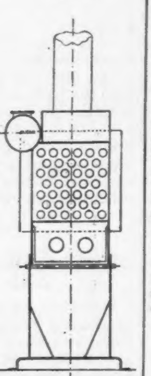

A water-tube boiler may be defined simply as an assemblage of tubes filled with water and placed over a fire. The ends of the tubes are fixed to two receivers, which combine the whole together. If the receivers be cylindrical where the tubes fit, then the tubes are more or less bent to suit; if flat, the tubes are generally straight. The advocates of bent tubes claim the bending as important in taking up or accommodating themselves to the expansion of the boiler when under steam. On the other hand, those who advocate the straight tubes find no difficulty arising from this point. Straight tubes offer the best advantages in respect of inspection, cleaning, and renewals. The experiments were made with a small model boiler—see Figs. 1 and 2—containing thirty-nine straight tubes, each ⅜in. diameter by 9in. long, containing 2·9 square feet of heating surface. The receivers to which the tubes were attached were flat, the end plates were of glass, so that the tubes could be seen right through, and the action going on inside could be distinctly observed. A steam receiver was also placed on the top, connecting the other two receivers. Heat was supplied by two Bunsen burners, consisting of two tubes with cross slots, the heating taking place being very much similar to that of an ordinary fire-grate furnace. The model was so constructed that it could be used or tried in a great number of different positions. The object of the first series of experiments was made with a view of finding out the relative value of heating surface when the tubes were angled from a horizontal position gradually to that of a vertical one, or through an angle of 90 deg. The experiments were conducted at atmospheric pressure, and commenced by first raising a given weight of water to the boiling point, and then ascertaining the amount evaporated after an interval of fifteen minutes.

After a few preliminary trials it was found that when the boiler was angled about 10 deg. from the horizontal, the evaporation was highest, viz., 8½ oz.; when the angle was increased to 15 deg., the evaporation was 8¼ oz.; 30 deg., 7½ oz.; 45 deg., 6½ oz.; 60 deg., 5¾ oz.; 75 deg., 5½ oz.; and 90 deg., 5 oz. Again, on reducing the angle to 5 deg., the evaporation was 8¼ oz., and when level 7½ oz. It may be here stated that, owing to the pressure of gas varying a little, very seldom the same results could exactly be arrived at; but by making several trials the above is a fair average. This is graphically represented in Fig. 3—top curve; the vertical ordinates representing the percentage of evaporation at the various angles at which the boiler was tried, beginning at the horizontal position and gradually rising to the vertical position. It was found when the boiler was angled 10 deg. it gave the best result; therefore, 10 deg. represents the maximum evaporation, or 100 per cent. In looking at this diagram, we find that in any water-tube boiler whose tubes are inclined, say, 10 deg., by merely increasing the angle to 30 deg., the amount of water evaporated is reduced from 100 to 85, or 15 per cent. less. If the angle be increased to 60 deg., the decrease will be 33 per cent. And at 90 deg., or the tubes vertical, the reduction is a little over 40 per cent. This compares very favourably with the old-fashioned rule employed in the ordinary steam boiler, of allowing two square feet of vertical heating surface to be of equal value to each one of horizontal.

FIG. 2A.

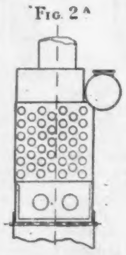

FIG. 3.

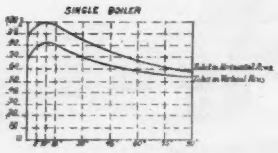
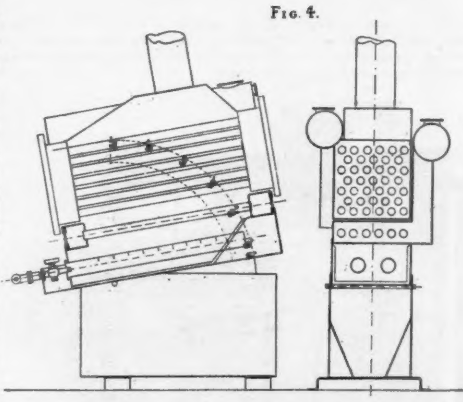


These experiments were conducted with the tubes placed in horizontal rows, so as to allow the products of combustion to travel in a zig-zag direction to the funnel. The next series were taken with the boiler turned on its sides, so as to form the tubes into vertical rows, and give the products of combustion a more direct course to the funnel—see Fig. 2A. The result is shown by the lower curve on Fig. 3. The highest percentage was 82 per cent. at 10 deg., and 53 per cent. at 90 deg., the best result showing a difference of 18 per cent. in favour of the former arrangement of tubes. Instructive as these tests may be, the next series will show still more striking results. In order to arrive at the duty performed by various tubes or rows of tubes, and more especially those nearest to the source of heat; if we take another boiler—or rather a part of a boiler representing that row of tubes which is nearest to the fire—and place the two together, as represented in Fig. 4, we have the means of arriving at the evaporation of each boiler separately. This small boiler consists of six tubes only, having a heating surface of ·44 square feet, compared with the larger one of 2·9 square feet, or a combined H.S. of 3·34 square feet.

FIG. 4.



The results of this arrangement are represented on diagram Fig. 5. The upper curve shows the combined evaporation of both boilers, and although there is an augmented H.S. of about 15 per cent., yet there is very little difference in the amount evaporated. The lower curve shows the evaporation of the original or larger boiler, and we now see that at its best it is reduced from 100 per cent. to 40 per cent. at 10 deg., and from 60 per cent. to 17 per cent. at 90 deg. On the other hand, the small boiler is represented by the middle curve, and its evaporation at its best is 60 per cent. at 10 deg., and 45 per cent. at 90 deg. The above results may be stated in other words, viz.:—That practically 60 per cent. of all the steam generated in any water-tube boiler with tubes at any angle is generated in the first or nearest row of tubes to the fire. The remaining 40 per cent. is left for the larger portion of the boiler to accomplish. By reversing the positions of the two boilers—by placing the smaller on the top of the larger one—we can arrive at the evaporation of the top row; but this was found to be so small as not to be taken notice of. The writer had not the means of testing the intermediate rows; but the following nearest table will not be very far off:—

FIG. 5.

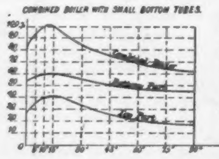


FIG. 7.

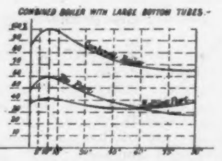
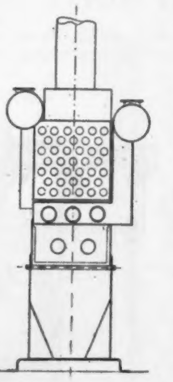


1st row nearest to the fire evaporated	60·0	p.c. of the total evaporation
2nd " " " "	24·0	" " " "
3rd " " " "	9·5	" " " "
4th " " " "	3·5	" " " "
5th " " " "	1·5	" " " "
6th " " " "	1·0	" " " "
7th " " "	0·5	" " " "
	100·0	

The importance of the above cannot be overlooked. Either the first row is doing too much or the back row too little; and the conclusion arrived at is that, practically, the first row is receiving the whole wear and tear of the boiler, therefore more liable to damage and renewals. This has proved itself in the case of copper tubes, which, although a better conductor of heat than either iron or steel, yet were unable to stand the severe work they had to perform. The danger from overheating and rupture is not only very unpleasant from a stokehold point of view, but the giving way at some critical moment demands our most important consideration; in short, it is the vital part of the water-tube boiler.

Seeing this difficulty some time ago, the writer devised some means by which the first row was relieved of this heavy duty, and more laid on those immediately behind. This is accomplished by substituting tubes of much larger diameter nearest to the fire than those which are more remote. The larger tubes contain more water, and present less heating surface for the space occupied than those of smaller diameter. The result is that the evaporation is less with the larger tubes but greater with the smaller. Fig. 6 represents the arrangement. For the six ⅜in. tubes we now adopt three ¾in. tubes in their place. The weight of water in the three tubes is double that in the six smaller ones, while the heating surface remains the same. The diagram representing the results of the trial is shown on Fig. 7, the top curve as before representing the results of the two boilers. Practically there is very little difference compared with the similar top curves of Figs. 3 and 5; if anything it is slightly in favour of Fig. 7. But when we come to compare the two lower curves with the similar curves in Fig. 5, we find that they have almost changed places. Taking the top or larger boiler, the evaporation at 10 deg. is nearly 60 per cent. of the total as compared with a little over 40 per cent. shown on the former trial, the curve dropping down at 90 deg. to 27 per cent. against 17 per cent. Taking the lower boiler, representing the three large tubes, the evaporation is reduced from 60 per cent. to a little over 40 per cent. at 10 deg. with the larger tubes, terminating at 38 per cent. at 90 deg. It will be observed that the two curves cross each other when the boiler is at an angle of about 55 deg., showing that the evaporation at this angle is about equal in each boiler. From this point on to 90 deg. the smaller boiler evaporates more than the larger; but, as the angle decreases below 55 deg., the larger boiler evaporates more than the smaller. We here see that the evaporation in the first row of tubes is very much reduced, there is less liability to overheating, and accidents are reduced to a minimum. The quantity of water evaporated by the first row of small tubes was at the rate of 5 lb. per square foot of heating surface per hour, and the velocity at the end of the tubes about 3·8ft. per second. The tubes were full of semi-steam and water, so that no light could be seen at the other end; evidently these tubes were evaporating their maximum quantity with efficiency. On the other hand, with the row of large bottom tubes, the rate of evaporation was about 3·5 lb. per square foot heating surface, and the velocity at the tube ends—steam only—about 2·9ft. per second. Up to an angle of about 60 deg. a light could be distinctly seen through these tubes, the steam occupying about one-third of the area on the top side, the water underneath presenting a clear solid mass. Above 60 deg. elevation the water and steam became more or less mixed up, so that a light could not be seen at the other end. From the apparently easy manner in which these tubes were doing their work, it was evident the maximum amount of evaporation had not been reached. There was a large reserve of solid water in the tube, and the steam appeared to pass freely away without taking any water along with it. Indeed, there could not be a strong water current, for on blocking up the bottom end of one tube to the extent of reducing its area to one fourth, there appeared to be no different result. It must be remembered that the above trials were made at a pressure of one atmosphere, where the relative volumes of steam and water are as 1640 to 1. For higher pressures a corresponding rate of combustion may be adopted.

FIG. 6.



The most vital parts in any water-tube boiler, and the most easily damaged by overheating, are those tubes in close proximity to the fire. To overcome this difficulty two courses are open: (*a*) by adopting small tubes and providing for a vigorous circulation; (*b*) by adopting larger tubes and a less active circulation. Adopting the former, there is a limit both in respect to the speed of the current and the quantity of steam in contact with the heating surfaces. According to Mr. Thornycroft's experiments, at a pressure of three atmospheres, the relative volume of steam and water passing through a number of 1½in. tubes was about 5·4 to 1, and at twelve atmospheres this would equal 1½ to 1, or three volumes of steam, at an average, in each tube, to two of water. A condition of things which presents to us two evils, one is the danger arising from the tube becoming much hotter than the temperature due to the pressure. As an instance of this, there is the failure of copper tubes in water-tube boilers to stand this excessive heat. The second evil is the slow corrosion taking place, owing to part of the steam in contact with the tube becoming decomposed at a high temperature, forming oxide of iron and hydrogen gas. Some years ago apparatuses for superheating steam were placed in uptakes; but even at this low temperature their life was three or four years at the most. By the improved arrangement of larger tubes to face the first and direct action of the fire, a larger body of more solid water is in actual contact with the heating surfaces. The liability to damage by over-heating is reduced to a minimum; the duty of the various tubes more evenly distributed, and the steam generated more freely disengaged.

In conclusion, there is one point which, during the time these experiments were being made, confirmed the writer's views more strongly of a grave defect in Belleville water-tube boilers for marine purposes, and, as this boiler is now being freely adopted by our Admiralty, his humble protest must be taken from a taxpayer's point of view. Those who are responsible for the position and arrangement of this boiler on board of a sea-going vessel have evidently not given the subject of an unsteady platform any consideration. Numerous tubes have given way at sea; not that it is the only boiler which suffers from defective tubes; but in all probability these same tubes would not have given way had the boiler not been tossed about in a sea way. In many instances these tubes have been replaced by thicker ones, and in some cases by Serve tubes, with little better results. Still the true cause of their failure is not discovered, therefore no effectual remedy applied, and thus the error is repeated.

The arrangement of all water-tube boilers, with horizontal or slightly inclined tubes on board ship, should be parallel with the line of keel. But it appears to be the rule, so far as this boiler in question is concerned, to place the same across the ship. Now, the inclination or angle of the Belleville boiler tubes is about 2 deg. or 3 deg. from the horizontal, and as, 10 deg., say, is not an uncommon angle for a ship to roll at sea, it follows that the tubes will become depressed or angle reversed to the extent of 7 deg. or 8 deg. A ship to roll from eight to ten rolls per minute is not uncommon, and therefore six or eight seconds would be the duration of one roll. Now, imagine the ship rolling, a heavy fire on the grate, and in this time these lower tubes generating, as we have seen, such a large volume of steam, which would immediately reverse the circulating current, fill the upper ends and be here imprisoned, only to be relieved by the next roll. The greater portion of the steam will now be transferred to the other end, to be again re-imprisoned, and so on till the ship gets into less turbulent waters. With reference to what the continued effect on these semi-dry tubes would be in a sea-way, or in the event of the ship having a list, the result is left for your better and impartial judgment.

---

* Read at the Thirty-seventh Session of the Institution of Naval Architects, March 26th, 1896.

RAILWAY MATTERS.

Mr. Piesse has been appointed Minister of Railways and Public Works of Western Australia.

The first sod of the Ahmedabad-Prantij Railway was cut by his Excellency the Governor of Bombay at Ahmedabad, on the 15th ult.

The railway companies concerned in the Royal Agricultural Society's showyard traffic at Leicester have agreed to reduce the rates for cartage to and from railway stations and the showyard to the following amounts:—General traffic, machinery and agricultural implements, 3s. 6d. per ton; machinery and agricultural implements hauled on their own wheels, 3s. per ton.

The London and North-Western Railway Company has commenced the work of tunnelling under Crewe Station. The present station will be left free for passenger traffic only, whilst goods traffic will be conducted through the tunnel, and goods sheds will be erected at Basford Wood. Several hundred men are engaged excavating, and the work, it is said, will occupy several years.

The Kington and Eardisley Railway Company has given notice that it does not intend to proceed any further with the deposited Bill for the present session. The scheme was regarded favourably from a passengers' point of view. It was to construct over twenty miles of railway to run from a junction with the New Radnor extension to a point between Llandrindad Wells and Newton, and thus form connection with the Mid-Wales and London and North-Western Railway.

The North-Eastern Railway Company has opened a new deck at West Hartlepool for the accommodation of the timber trade of the port, the work which cost between £30,000 and £40,000, being executed by Messrs. T. D. Ridley and Sons, of Middlesbrough. The work has been going on for two years, and includes a mole upwards of 800ft. long, at which six timber laden vessels can be discharged at a time. The railway company undertook the work mainly at the solicitation of the timber importers who found their trade crippled and curtailed by want of sufficient quay space.

The Prefect of the Seine was recently applied to for permission to put horseless carriages into current use in Paris, along with the public carriages of that city. The special form of motor involved is a petroleum motor. The Chief of Police reports to the Prefect that he sees no objection to granting the authority. He believes, however, that these petroleum carriages should be placed at the end of the cab stands, in order not to interfere with the free movement of the ordinary carriages in taking their places on the cab stands, and that the two kinds of vehicles should not be mixed in the line on one stand.

All the railway carriage and wagon companies, writes our Birmingham correspondent, have found a great improvement in trade since the beginning of the year, and are busy. We understand that the Oldbury Railway Carriage and Wagon Company have some large contracts for saloon carriages and wagons for the Cape Government Railways; and also wagons—four-wheeled and bogie—for the Western Australian Railways. They are also engaged on carriages for the South-Eastern Railway, Midland and South-Western Junction Railway, and the Glasgow District Subway, as well as upon hopper wagons for Spanish copper mines.

The success of electrically welded rails was recently discussed by Mr. Robert McCulloch in a paper before the Engineers' Club of St. Louis. Some 3¼ miles of double track in St. Louis had been connected up with electrically welded joints. Out of a total of 2203 joints thus treated, 3·27 per cent., or seventy-two, have parted. The fractures occurred in two successive cold snaps of last winter. Repairs were made by casting a mass of iron around the joint. The amount of opening at the fracture varied from 2in. to practically nothing. Strange to say, the heat of the following summer caused very little variation in the width of the openings.

Shortly after the Easter recess an important report on the purchase and leasing of tramways will, according to the *City Press*, be presented by the Highways Committee of the London County Council. It will be remembered that just before last Christmas the Council discussed the advisability of coming to some arrangement with the Tramway Companies with regard to the purchase of those portions of the lines which had been reconstructed under new Acts, and which did not in the opinion of the Companies become purchasable at the time that the term for the original lines expired. Since then negotiations have been in progress, and it is likely that the report, when presented to the Council, will be an agreeable surprise to the ratepayers, and one which will redound to the credit of those who took part in the negotiations on both sides.

Two locomotive boiler explosions were reported in the States during the week before last. The first took place on the Delaware, Lackawanna and Western Railroad, near Cassville, N.Y., on February 19th, killing the engineman and fireman. The train, comprising baggage and passenger cars, was running at its usual speed. The engine was torn to pieces, and the trucks left the track, the mass of broken and twisted iron toppling over into the ditch. The cars remained on the track, and no passengers were injured. The cause of the explosion is stated to have been low water. The second explosion was on February 20th, on a freight train on the Nashville, Chattanooga and St. Louis Railway, near Bridgeport, Ala. The engine was a Baldwin consolidation, and the explosion rent it into a thousand pieces, some of which were thrown hundreds of feet. The engineman and fireman were killed.

On his arrival at Coolgardie on Monday, by the first through train from Perth, the Governor of West Australia drove the last spike in the presence of a great concourse. At the luncheon afterwards, he said the ceremony was not only interesting to those actively engaged in it beneath the burning sun and on the sandy plain, but to thousands throughout the world who had millions invested in Coolgardie and the surrounding district. The welcome news of the opening of the line would be cabled to London, Paris, Vienna, St. Petersburg, and all the great commercial centres. The event, therefore, was not merely of local, but of national, of even world-wide, importance. From what he could hear, he felt convinced of the permanence of the goldfields. He therefore expected that other railways would shortly be undertaken, probably including one to place Coolgardie in direct communication with the eastern colonies.

The present week is the busiest week of the year, from the fast train point of view, with the Manchester, Sheffield, and Lincolnshire Railway Company. During the first three days they have the Lincoln races, and during the last three days the Liverpool races, including such important events as the Lincolnshire Handicap and the Grand National. On Wednesday evening, at the close of the Lincoln races, the racing world were transferred by the Manchester, Sheffield, and Lincolnshire trains from Lincoln to Liverpool, *viâ* Sheffield. All these fast and heavy trains were worked by the new class of engine Mr. Harry Pollitt, locomotive engineer, Gorton Works, recently got out as illustrated in the special double-page supplement in last week's Engineer. At Gorton there has just been turned out the first four of the sixty-six goods tender engines being built there. These are the only goods engines with Belpaire boilers, and this feature naturally makes them conspicuous. Mr. Pollitt has used them on goods and passenger tank engines for the last two years, working night and day with unbroken success, but it is a new feature entirely, even with the Manchester, Sheffield, and Lincolnshire, to have a Belpaire box on a goods tender engine.

NOTES AND MEMORANDA.

The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 19·2 per 1000 of their aggregate population, which is estimated at 10,860,971 persons in the middle of this year. The London rate was 18·8, or lower than the average of all the great towns.

In an old MS. book referring to "Steam Ploughing with Boydell's Engine, near Louth, July 31st, 1857," the following record has been found:—"Ploughed on Mr. J. Robson's land with Burrell's double-breasted ploughs 23 acres. Ploughed one acre in 73 minutes. Cost of labour and coals per day £1 12s."

A French process for preventing rust on steel and iron is said to produce a bluish coating, which does not crack or peel off, even if the metal be bent through an angle of 45 deg. The articles are subjected to a heat of 650 deg. Centigrade in a gas retort for twenty minutes, and then hydrogen is turned on for another three-quarters of an hour. This is followed by the introduction of a small amount of naphtha for a period of ten minutes; after which the hydrogen is again admitted for a quarter of an hour. The retorts are allowed to cool down to 400 deg. Centigrade, and the articles are removed.

A paper on "The Carbides of Yttrium and Thorium" was recently read before the Paris Academy of Sciences by MM. H. Moissan and Etard. Yttrium carbide, prepared in the electric furnace, is attacked readily by the halogens, with difficulty by acids. With water the carbide yields a mixture of acetylene—72 per cent.—methane, ethylene, and hydrogen, together with a small quantity of liquid hydrocarbons. Thorium carbide produced by a similar method forms a crystalline transparent mass, and gives a mixture of hydrocarbons on treatment with water of the same qualitative composition, *Nature* says, as that obtained from yttrium carbide.

The report of the committee, appointed in May of last year, to inquire into the causes of the explosion, and the precautions required to ensure the safety, of cylinders of compressed gases, states that the risks of explosion fall into two classes, viz.:—(1) risks due to negligence in the manufacture, annealing, and testing of the cylinders; (2) risks due to neglect of precautions in filling the cylinders. As the manufacture is carried on very extensively, and is likely to increase, the committee think that the risks would be reduced if there were some control of the trade of making cylinders by official inspection. They suggest that there should be a general inspection of all factories manufacturing compressed or liquefied gases. If an inspector were satisfied that the arrangements at any factory were adequate, and that the precautions laid down in this report were being taken, a certificate would be granted authorising such factories to test and mark cylinders. It is suggested that a first thorough inspection, and an occasional inspection subsequently, at intervals of about six months, would be sufficient as a ground for granting and renewing certificates.

The report of the Board of Engineers appointed to investigate the plans and cost of construction of the Nicaragua Canal for the United States Government says the most serious problems are those involved in the heavy rainfall and consequent discharges from the lake and streams, whose variations of surface and volume must be taken into account. The rainfall record at Greytown for three years shows a mean of 267in. A record at Rivas, on the west side, for fourteen years gives a mean of 65in. In addition to these there is trustworthy information of precipitation of 3in. in an hour, of 9in. in nine hours, and 35in. in eight days. A record of nearly 25ft. of water in a year on the Caribbean coast, diminished to 5½ft. between the lake and the Pacific, indicates the important results that must ensue with reference to matters of local drainage and engineering construction. In regard to the Ochoa dam, as proposed by the company, the report says this dam is to be a rock fill across a powerful river on sand foundation. A dam so constructed, the Commission says, has no precedent, and its erection in conflict with the unknown volume of the floods presents grave difficulties. The official estimate by the company is 66,466,880 dols.; by the Commission it is 133,472,803 dols.

Thorite is a bi-hydrated silicate of thorium, lime, iron, manganese, uranium, &c., containing about 58 per cent. of thorine, or oxide of thorium; and orangite is a variety of the same mineral, still richer and rarer, a sesqui-hydrate, which contains 75 per cent. of thorium. These, the principal ores of thorium, and a few others, are special to Norway, being chiefly found in veins of pegmatite on the south-east coast between Arendal and Laurwik, although only from two to three tons were produced last year. These minerals are causing great interest on account of the important part they play in gas burners of the Auer and Welsbach type. Although probably North America will be able to send away large quantities of thorine, extracted from the monazites of that country, Norway is at present almost the only source of supplying these rare minerals. On account of their extraordinary luminous capacity when in an incandescent state, thorium ores obtain fancy prices, very pure orangite realising nearly 500f.—£20—and thorite on an average 100f.—£4—per kilog.—2·2 lb. On account of the great demand for these ores, the old felspathic tips are being picked over; and prospectors cover the region, hammer in hand, seeking for thorite in the pegmatites or their immediate neighbourhood. As the Government engineer had classed thorium among metals subjected to the domanial *régime*, reports of discoveries were numerous in the office of the engineer-in-chief, who issued several thousand provisional concessions—*mutingsbreve*—extending over an area equal in size to a small English county. Competent authorities, however, protested the assimilation of thorium to metals occurring in regular lodes, which are subject to the domanial *régime*, so that the concessionnaires, to make themselves secure, entered into agreements with the surface owners. Norwegian savants are now ranged on two sides, for and against thorite being regarded as a crown mineral; and numerous petitions have been sent in to the Chamber on the subject.

According to provisional returns published by the German official Gazette, *Deutscher Reichs-und Staats-Anzeiger*, last year's total production of coal—*Steinkohle*—was 72,605,341 tons, against 70,644,069 tons in 1894, with 270,701, against 267,424 hands; and of the above quantities the Dortmund district alone produced 41,145,745 tons last year, against 40,613,073 tons in 1894, with 154,699, against 152,638 hands. This district contains no lignite—*Braunkohle*—which, however, is contributed by the four remaining mine districts, that also produce true coal, viz., Breslau, Halle, Clausthal, and Bonn, which put out together 20,292,034 tons of lignite last year, against 17,762,572 tons in 1894, with 30,044, against 28,657 hands. The quantity of coal sold or consumed last year amounted to 70,512,916 tons, showing an increase of 1,982,353 tons, or 2·89 per cent. over the figure of 1894; while the production has increased by 2·78 per cent. and the seats of working by ten, so as to attain the number of 265. Though the number of pits producing lignite has diminished by 16, viz., from 384 to 369, the total production given above shows an increase of 14·84 per cent. over the figures of 1894, while the number of hands employed has also increased. Germany's exports of mineral fuel last year amounted to 12,873,354 tons—against 12,203,994 tons in 1894—made up of coal 10,360,838 tons, coke 2,293,328 tons, briquettes 200,374 tons, and lignite 18,814 tons, of which 24,275 tons of coal went to Great Britain and 43,637 tons of coke to Australia; while her imports last year of mineral fuel were 12,819,990 tons—against 12,149,723 tons in 1894—made up of 5,117,356 tons of coal, 461,778 tons of coke, 59,806 tons of briquettes, and 7,181,050 tons of lignite, of which 4,013,067 tons—comprising 3,972,664 tons of coal, 32,801 tons of coke, and 76,021 tons of briquettes—were sent to Great Britain. Thus Germany's exports and imports of mineral fuel last year about balance one another; the respective figures being 669,405 and 670,267 tons.

MISCELLANEA.

The sale is announced, on the 8th prox., of the plant and machinery of the Cone Paper Mill, Gloucestershire, by Messrs. Fuller, Horsey, Son, and Cassell.

The Royal Agricultural Society's trials of the Potato Planters which may be entered in competition for the Society's prizes in Class I. will commence at 9 a.m. on Tuesday, April 21st, 1896, at the farm of Mr. T. Lander, Knighton, near Leicester.

Owing to the continual washing away of the Sheppey Cliffs, the Admiralty have abandoned the coastguard station at East End-lane, Minster, about four miles from Sheerness, and have established a new station in the adjoining parish of Eastchurch.

The Lachine Rapids Hydraulic and Land Company, of Montreal, Canada, have placed an order with Messrs. Nell for sixty-six 54in. cylinder gate Victor turbines, together with all the gearing, shafting, &c., for giving the power to the electric generators. The power will be transmitted electrically into the city for street railway and lighting purposes. This, we believe, is the largest contract for turbines ever placed.

The attention of intending exhibitors at the Royal Agricultural Society's Leicester Meeting is directed to the fact that the last day on which applications for space at ordinary rates can be received is Wednesday, April 1st. All entries received at 13, Hanover-square, from Thursday, April 2nd, to Wednesday, April 8th, must be accompanied by fees at double rates, in accordance with published regulations. After April 8th, no entry can be accepted under any circumstances whatever.

The great tank of the Hessarghatta waterworks is practically completed, and the water stands about 29ft. deep, not much below the waste weir. This artificial lake has an area of about four miles square. There is a very slight leakage below the bund, but this is nothing to speak of. The approach to the left waste weir which is being cut is nearing completion. The channel has been completed up to the pumping station and even beyond. The pumping plant includes three triple-expansion pumping engines of 60-horse power each.

The celebrated works, long known as the Mersey Forge, are, it will be seen from our advertisement columns, to be let or sold. The works are amongst those of most historic interest in England, through their connection with the heavy forge work of the great steamships of from a quarter to half a century ago. In them have been carried out some of the most difficult and well executed work required for the machinery of the ships that live most in our memories, and in later years a great deal of the heavy land engine shafts have been made in them. The forge contains no less than eleven double-acting steam hammers up to 12 tons, and the machine shops contain a great quantity of machinery, principally of the heaviest kind.

The Secretary of State for Foreign Affairs has received from her Majesty's Consul at Lorenzo Marquez information to the effect that the Improvements Commission of that port will, up to the end of April next, receive plans and designs for a screw-pile lighthouse for the Cockburn Bank and for a tug-boat for the pilot service. The range of the light must be ten miles, and the lighthouse must contain accommodation for the keepers. The tug-boat must be of the compound system, 100ft. in length, 8ft. draught at stern, 500 indicated horse-power, and not less than ten miles an hour speed. The boat must accommodate captain, engineers, crew of eight, and two lifeboats. Further particulars can be obtained of the Commercial Department, Foreign-office, S.W., between the hours of 11 and 6.

In consequence of the increasingly onerous duties of the Public Works Department of the Corporation of Birmingham, a re-arrangement is proposed to the city surveyor's office in order to relieve Mr. W. S. Till, the city surveyor, of some of his at present too onerous duties. He receives at present £1000 a year, with an addition of £400 a year from the Drainage Board. It is proposed that Mr. Till should give up the work of the Drainage Board, except in a consultative capacity, and that he shall receive from the Council a stipend of £1600 a year as city surveyor, instead of the £1000 a year now allotted to him. It is further suggested that a deputy or assistant colleague shall be appointed at a salary of £800 a year, £400 of this amount to be paid by the Corporation to its assistant surveyor, and £400 by the Drainage Board to its engineer.

A Select Committee of the House of Commons presided over by Sir James Kitson, passed a Bill which confirms a provisional order granted by the Board of Trade to the Charing Cross and Strand Electricity Supply Corporation, authorising them to light with electricity the area of the Strand District Board of Works. The Bill has been opposed by the Metropolitan Electric Supply Company, which already supplies the Strand district, but it was put forward in evidence that, while the Metropolitan Electric Light Company uses the high-tension alternating current, the Charing Cross Company would supply low-tension direct current, which has advantages for those who require electricity for motive power and other purposes. This Bill has now received the sanction of both Houses, having passed the House of Lords before the dissolution.

The installation of the Hermite electrical sanitation process at the Victoria Military Hospital at Netley has now been working since the beginning of the year, and a visit of inspection was made a few days ago by the War-office authorities, who expressed themselves thoroughly satisfied, both with the effect on the main sewer and the effluent, and also with the remarkable improvement in the atmosphere of the various wards. The ward masters are also unanimous in their approval. The French War and Naval Departments have officially approved the system, and are considering to which of their stations it shall be first applied. The Brazilian Government have given instructions for the Marine State Hospital at Rio to be fitted with the Hermite process on the same lines as the Victoria Hospital, Netley. As to the success of the demonstrations of the Hermite process at Rio last year, it may be of interest to state that in that part of the city where the working of the plant has been continued, not a single case of yellow fever has occurred, though it is a most unsanitary spot and in previous years has suffered severely. Other parts of the city have suffered as usual from the periodical visitations of this scourge.

The following are the Royal Institution lecture arrangements after Easter:—Professor James Sully, of University College, London, three lectures on "Child-Study and Education;" Mr. C. Vernon Boys, three lectures on "Ripples in Air and on Water;" Professor T. G. Bonney, two lectures on the "Building and Sculpture of Western Europe" (the Tyndall Lectures); Professor Dewar, three lectures on "Recent Chemical Progress;" Mr. W. Gowland, three lectures on the "Art of Working Metals in Japan;" Dr. Robert Munro, two lectures on "Lake Dwellings;" Professor W. B. Richmond, R.A., three lectures on "The Vault of the Sixtine Chapel;" Mr. F. Corder, Curator of the Royal Academy of Music, three lectures on "Three Emotional Composers—Berlioz, Wagner, Liszt" (with musical illustrations); Mr. E. A. Wallis Budge, of the British Museum, two lectures on "The Moral and Religious Literature of Ancient Egypt." The Friday Evening Meetings will be resumed on April 17th, when a discourse will be given by Mr. G. Lippmann on "Colour Photography;" succeeding discourses will probably be given by Professor G. V. Poore, Colonel H. Watkin, C.B., Professor Silvanus P. Thompson, Professor J. A. Ewing, Professor J. A. Fleming, and other gentlemen.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

W. D. F.—*See notice on page* 323.
R. H.—*Consult our advertising columns.*
W. C. (Newcastle-on-Tyne.) *No prize is offered for a wheel or for any parts as separate or apart from a complete self-propelled carriage.*
J. W.—*We have not published any account of an engine worked by ammonia gas, and we do not know of such an engine.*
E. P.—*It is impossible to answer your question without further information concerning the battery. Any of the large electrical apparatus makers in Manchester will provide you with what you require, or supply you with new dry cells, which will probably be as cheap.*

PIN-MAKING MACHINERY.

(*To the Editor of The Engineer.*)

SIR,—I should regard it as a favour if any reader would put me into communication with a manufacturer of pin-making machinery.

Newcastle-on-Tyne, March 24th. C. C.

EXTRACTING WATER FROM MILK.

(*To the Editor of The Engineer.*)

SIR,—Could you tell me where I could purchase a small vacuum still suitable for extracting water from milk? B. J.

Liverpool, March 21st.

MUSTARD MACHINERY.

(*To the Editor of The Engineer.*)

SIR,—Would you kindly give in your next issue of THE ENGINEER the address of a firm from whom I can order a mustard seed decorticator.

Dublin, March 21st. R. D. C.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. *£0 14s. 6d.*
Yearly (including two double numbers) .. .. *£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. *£0 18s. 0d.*
Yearly .. .. *£1 16s. 0d.*
THICK PAPER COPIES—
Half-yearly .. .. *£1 0s. 3d.*
Yearly .. .. *£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, March 31st, at 8 p.m. Paper: "The Tampico Harbour Works," by D. E. L. Corthell, M.A., M. Inst. C.E.

GEOLOGISTS' ASSOCIATION.—Saturday, March 28th. Excursion to Galley Hill, near Northfleet, and Swanscomb Hill. Leave Cannon-street (S.E.R.) at 2.15 p.m. for Northfleet, arrive at 3.5 p.m. Thursday, April 2nd. Excursion to Swanage, Corfe Castle, and Kimeridge. Leave Waterloo by the 4.55 p.m. train. Excursion secretary, E. P. Ridley, F.G.S., 6, Paget-road, Ipswich.

DEATHS.

On the 20th inst., at No. 17, Holland Park-gardens, W., JABEZ CHURCH, C.E., M. Inst. C.E., of No. 55, Parliament-street, Westminster. Interment at Paddington Cemetery, Wednesday, 25th inst., at 3 o'clock.

THE ENGINEER.

MARCH 27, 1896.

THAMES FLOODS.

THE intervention of the Board of Trade has been solicited, with a view to the prevention or mitigation of the floods occasioned by the overflowing of the Upper Thames. An influential deputation has waited upon Mr. Ritchie for this purpose, and the Queen herself has addressed a communication to the President of the Board of Trade expressing her anxiety that something should be done to prevent the recurrence of these disastrous inundations, of which a notable example occurred in November, 1894. In addition, there was produced before Mr. Ritchie, by the introducer of the deputation, a letter in which Prince Christian as High Steward of the Borough of Windsor, addressed the Mayor of that town, expressing an "earnest hope" that means might be devised to remedy the evil complained of. The support of the Queen and that of Prince Christian being thus given to the appeal of a deputation itself comprised of influential representatives, it might be expected that the desired change would soon come to pass. But in the first place Mr. Ritchie explained that there was very little power at his disposal for accomplishing the purpose in view; and in the next place, the Conservators of the Thames on whose action all would depend, disclaimed the idea of being anything more than a navigation authority, pleading that they had no power to expend any money for the direct prevention of floods. If, in carrying out their proper functions, they could mitigate the severity of the floods, the Conservators were professedly quite prepared to render such service, and they were in the habit of asserting that they had already done so. Under these conditions it was obvious that the deputation had no very brilliant prospect before them. They pointed to the recommendations of a Select Committee of the House of Commons, which in 1877 was appointed to inquire into the Thames Conservancy Acts, and to report what amendments, if any, were required in order to deal more effectually with the injuries effected by floods. The Committee having carried out their inquiry, made several recommendations, and the deputation which waited upon Mr. Ritchie the other day argued that if these had been acted upon much injury would have been avoided. They now asked Mr. Ritchie, if he were able, to prevail upon the Conservators to carry out the plans which the Select Committee of nineteen years ago had thought advisable. If he lacked power for this purpose, it was asked that he would institute an inquiry into the reasons why the recommendations were not acted upon, and into the desirability of making some fresh arrangements for the control of the non-tidal portion of the Thames. The deputation wished it to be understood that they did not ask for any great drainage schemes, but they would be thankful for every inch taken off from the height of a flood.

The case was thus put in a very modest and practical form. What was the representative of the Government to say to it? Here was the Queen overshadowing all, pleading the sorrows and sufferings of the poor, as well as the effect of the floods on the general health of the district, and the fact that Eton College had to be closed for a time during the flood of 1894. The Head Master of Eton echoed this plea, and gave a graphic description of what was the result of a big flood in the Thames Valley. Mr. Ritchie was in full sympathy with the deputation, and felt the force of the royal appeal. He would make representations to the Conservators, and try the utmost of his persuasive powers in that quarter. He would try to get a member on the Board who should be independent of the navigating interest. He would give careful consideration as to whether there should be another inquiry into the question of the floods, and as to whether it was desirable to set up another drainage authority. He was prepared to admit that the Conservators were right when they said they were not a flood authority, though he was of opinion that they could do much to reduce the magnitude of the floods, by the manner in which they carried out their special functions. On the whole, we cannot gather much hope from the present state of affairs. There is one recommendation made by the Select Committee which lies out of the range of the Conservators, and for the lapse of which they are in no degree responsible. It is that for the purpose of drainage, and for the prevention of floods below Long Wittenham, the proper course would be for riparian owners and occupiers to unite and obtain powers to establish an arterial drainage authority, the work for whom, it is thought, might be conveniently carried out by the Conservators. This kind of dual control seems open to objection, as likely to result in friction and cross purposes. But the principle at the root of it is that of rates, and it is tolerably certain that if anything effectual is to be done with regard to these floods, there must be a rating power somewhere to raise the necessary funds. There has been plenty of talking, there have been sundry meetings, and there has been a sufficiency of resolutions. But nothing practical can come of it all, unless money is provided, and thus far it is the money that is wanting.

Good authorities seem to agree in the conclusion that Thames floods cannot be wholly prevented. All we can hope for is to see them mitigated. It is a problem of inches. Every inch will cost something, and a good many inches will demand a round sum. The Select Committee stated that, in order to prevent floods from submerging lands and dwellings throughout the Thames Valley, works of enormous cost and magnitude would be required. But the Conservators say that works might be carried out at a moderate cost which would undoubtedly mitigate the inconvenience and suffering caused by the overflow of the river on the adjacent lands and property, both by lessening the extent of a flood and shortening its duration. A report from Mr. Charles J. More, the Engineer of the Conservators, specifies these works, but states that they are "flood works;" and the Conservators go on to say they are "advised" that they have "no power to expend their funds thereon." Perhaps it might be urged that although the navigation could do without the flood works, yet the flood works would make it all the better for the navigation. It is not entirely clear where the line is to be drawn between one class of works and the other. Floods are often obstructive to the navigation. To get rid of them entirely is doubtless impracticable, but it must be perfectly possible to keep them within narrower limits than those to which they now extend. Flood works on a large scale are fearfully expensive. The Engineer to the Conservators states that in 1882 he reported on the works necessary to be done to relieve the lands between Staines and Teddington from the injurious effects of floods. He found that to keep even a moderate flood within the ordinary channel of the river would cost in that district alone the sum of £85,000. In 1878 Sir John Hawkshaw reported on the relief work necessary between Cricklade and Long Wittenham, and estimated the cost at upwards of £130,000, exclusive of engineering and legal expenses. This scheme, also, was only intended to deal with ordinary floods.

But while these grand schemes for controlling the river are too costly for serious consideration, it is shown that there are lesser works which are fairly within compass as a burden on the rates. If a really effective plan for reducing the level of the more serious floods demands a systematic enlargement of the sectional area of the river, by widening and deepening the channel, it is certain that no reasonable sum will pay for it. But a moderate outlay will suffice for what is described as the dredging away of local shoals in the river, the clearing out of side streams and backwaters, and the removal of many obstructions which have been deliberately placed, or allowed by neglect to grow up, at spots where provision was originally made for the free passage of flood water. Unfortunately, to deal with these matters is simply to carry out a palliative policy, and it might be urged that even some of this work properly belongs to the Conservators, though they think otherwise, or, as they say, are "advised" to that effect. The vastness of the complete problem is well shown by Mr. C. J. More. Taking his account of the matter, we might almost look upon the Thames as a natural failure. He considers the chief cause of the inundations to consist in "the insufficiency of the ordinary channel of the river to carry off an excessive rainfall." In proof of this he states that the amount of water poured into the river above Teddington, throughout its drainage area of 3800 square miles, occasionally exceeds four or five times the quantity which can be carried within its banks. Still, even this does not preclude doing what can be done. It does not appear that there is much value in the proposed telegraphic and telephonic communication between the several locks. Mill rights have to be respected, and the lock-keepers cannot begin to run the water off until it has risen above a certain level. That point being reached, as shown by a fixed mark, the lock-keeper proceeds to raise the weir sluices, and he cannot legally do so at an earlier stage. It is asserted as a matter of fact that, long before a flood has attained a level which threatens serious consequences, all the tackle at the weirs is drawn. As a general result, there seems little prospect of any marked improvement in regard to the floods, unless the Conservators are endowed with rating powers for the purpose, or unless an actual drainage authority is created with powers of that description. It is an unfortunate fact that when, in 1870, the Conservators brought in a Bill to afford them rating powers, the opposition offered both by landowners and towns was such that the attempt proved a failure. It is thought that the inhabitants of the riparian districts would be wiser in the present generation. Perhaps they would yield the point, if they saw they would thereby obtain deliverance from the calamitous floods by which they now so frequently suffer. Taking a broader view of the subject, it certainly seems far from creditable for a river like the

Thames to be so exempt from control as to create a flood by which Eton College had to be closed, and the Queen narrowly escaped being driven from Windsor Castle, while in the dwellings of many of her subjects there was neither fuel, artificial light, nor water fit to drink, gas-works and waterworks being in several places alike overwhelmed.

AMERICAN LOCOMOTIVE PERFORMANCE.

Our indefatigable American correspondent has succeeded in obtaining for us a section of the line between Erie and Buffalo Creek. This will be found on page 313. Over the 86 miles of road it is claimed, as our readers will remember, that on October 24th, 1895, the fastest run on record was made, the total time being 70 minutes 46 seconds. The average speed was 72·91 miles per hour. An examination of these sections serves to strengthen our statement that the performance sets at defiance all our preconceived ideas concerning the capabilities of locomotive engines. All that we have written on the subject we hasten to withdraw. Our calculations of work were based on the assumption that the line was either level or that the maximum speeds were in all cases attained on falling grades. This it seems was not the case. The speed up the hills was not only far in excess of anything ever touched in this country, but gradually augmented instead of falling off. Thus, in one case, the train starting at the foot of an incline, five miles long, of 1 in 333 at 67·12 miles an hour, had attained at the summit a velocity of 81·44 miles an hour. If we had not official testimony to the truth of this statement we should not believe it. Yet this, it will be seen, is only one instance of acceleration on rising grades. An engine which, with 134 tons behind it, can run up an incline of 1 in 333, five miles long, at an average speed of 74 miles an hour deserves all the attention it can receive. When, furthermore, it is remembered that it would be regarded in this country as a big goods engine, we may well stop to ask whether all our existing notions on the subject of running express trains are not wrong. Are we not justified in concluding that a small wheel is better for such work than a large one, and that the use of coupling rods is a distinct advantage instead of being a defect? On these points we shall leave our readers to draw their own conclusions, and proceed to explain a little in detail what the whole story means.

The train consisted of three cars, two of which weighed 41·3 English tons each, and the third 52 tons. The total weight behind the tender was 134 tons, with the ten-wheeled six-coupled engine, with which alone we have to do; the total weight of the engine, tender, and train at starting was 225 tons. As, however, water and coal were used pretty freely, we deduct five tons, and take the average weight, including passengers, who were few, at 220 tons. It has been estimated at the very high speeds attained the average resistance was only 15 lb. per ton. It is, of course, difficult to credit this, especially when we remember that the engine has ten wheels, and that the drivers are only 5ft. 6in. diameter, and coupled. However, at 15 lb. per ton we have a total resistance of 220 × 15 = 3300 lb. The resistance due to gravity was $\frac{492,800}{333} = 1480$ lb., and $3300 + 1480 = 4780$ lb. as the total smallest possible resistance up an incline of 1 in 333. We shall, to avoid complication, leave out of consideration the work of acceleration, and content ourselves with treating the performance as though the speed was, as we have said, 74 miles an hour, or 6512ft. per minute. To overcome a resistance of 4780 lb. at this speed demands 944-horse power, omitting fractions, which is much in excess of the figures we have arrived at in previous articles, which were, of course, based on different data. The tractive power of the engine was 116 lb. per pound of cylinder pressure, and the average effective pressure must therefore have been about 40·5 lb.; and considering the enormous piston speed attained, and the great difficulty met with under the circumstances in getting the steam out of the cylinders, the total pressure must have been very large, yet the coal consumption shows that the rate per horse was under 3 lb. But, of course, it must not be forgotten that the engine was not always working up to the power we have given. It is, however, very difficult to believe that the economic rate of evaporation could have been so high as is stated.

In order to keep criticism within reasonable limits of length we have dealt with only a few miles out of the whole length. Our readers can, and no doubt will, make calculations and draw deductions for themselves for the remaining portions of the run up hill and down dale. It does not affect the fact as a whole that we have selected the climbing of one hill only, but it will be seen that much the same work was done very shortly after this final run began. All the figures are before our readers, and they can draw their own conclusions. Take the story how we may for the rest it will be seen that as regards this particular five miles of climb we have a most astonishing and unprecedented performance, even if we take the resistance at the enormous speeds stated to have been reached at only 15 lb. per ton. It puts some stretch on our credulity, however, to believe that the resistance of the cars could have been as little as this; but we confess we cannot believe it at all as regards the engine. To avoid the chance of being misunderstood once more by our United States contemporaries, it is necessary to explain here that we are not now referring to internal engine friction, but to the resistance of the locomotive regarded as a vehicle. It is well known that coupling even two pairs of wheels augments resistance considerably; and six coupled engines with small wheels are very unfavourably placed as compared with engines with one pair of large drivers only. It seems to us to be incredible that an engine and train weighing 220 tons could be hauled up an incline five miles long at a continually accelerated speed, averaging 74 miles an hour, by a weight of 4780 lb., or little over 2 tons, pulling at a rope passed over a pulley at the summit of the incline. This is really the way to look at the question of train resistance; it clears our ideas at once. But, on the other hand, if we assume that the resistance was much greater than 15 lb. per ton, we are compelled to believe that the performance of the locomotive was truly marvellous. At a velocity of 6512ft. per minute, each 100 lb. of resistance represents about 20-horse power. If the resistance of the train were augmented by 5 lb. per ton, or 1100 lb., that would represent 220-horse power; but it is very difficult to reconcile any greater horse-power than that we have stated with the consumption of coal per mile.

It is, of course, out of the question to doubt the accuracy of the figures placed in so much detail before us by our correspondent. But we ask ourselves whether, after all, Mr. Stroudley was not right when he said that no one in this country knew how fast a locomotive with a light train could run, because no one had ever tried. He told us that on one occasion he had attained 80 miles an hour with the Grosvenor, as recorded by the speed indicator in the cab. The engine could have run faster, but no one in the cab wanted a higher speed. "Eighty miles an hour was quite fast enough for us." We do not hesitate to say that there are very few men in this country who would risk their necks by attempting to run a six-coupled goods engine at 90 miles an hour. It requires no calculation to see that every moving portion of the engine must been taxed pretty near the ultimate limit. Few of us would care to stand on a foot-plate, with side rods making nearly 500 revolutions per minute. But the experiment has been made, and no one has been a bit the worse, and we may consider what is the lesson taught. To us it seems to be simply that on which we have often insisted. The boiler is the measure of the capabilities of any locomotive. Within limits, cylinder capacity is quite a secondary consideration; but when this is conceded we have a vista of changes opened up before us. If speeds of 90 miles an hour can be got out of goods engines, what may not such single engines as those on the Great Western, Great Northern, and Midland, be able to accomplish if only we give them 1600ft. or 1700ft. of heating surface instead of 1200ft. or 1300ft.? Always provided, of course, that the augmented surface does not mean an extra foot or two of length in the tubes, which adds only little to the power of a boiler, although it promotes economy.

BOILERS AT ELECTRIC LIGHT STATIONS.

There is a cause for everything, if not a reason. It is not always easy to see what the cause may be, or to be satisfied with the reason. But the fact remains. In electricity manufactories or electric light stations, whichever they may be called, it is noteworthy that steam is generated on a system different from that which has for half a century at least satisfied millowners, and indeed manufacturers of almost all known commodities. For ordinary manufacturing purposes the Lancashire or the Cornish boiler is used almost to the exclusion of all other types. The former is no doubt an excellent example of the survival of the fittest, and its all but universal adoption is the result of a careful calculation based on commercial principles. From the first, however, the Lancashire boiler has been almost absent from electric light installations. It is only recently that it begins to be used in a tentative fashion by electric light engineers. In not only the United States, but this country as well, we find that boilers of the water-tube or locomotive type are nearly always employed to drive electrical machinery. There must be some reason for this. We do not think that it has ever been stated; but it does not seem to be far to seek, and when found it is instructive.

When electric light stations were first designed in this country the designers were in almost every case electricians, not mechanical engineers; or at least not mechanical engineers possessing any considerable commercial knowledge of the working of steam machinery. These gentlemen knew from books that high-pressure steam was more economical than low-pressure steam, in the sense, at least, that a smaller weight of the former than of the latter would give a horse-power, so it was determined that high-pressure steam must be used. But the Lancashire boiler was not deemed suitable for pressures over 100 lb., so recourse was had to water-tube boilers; and to locomotive type boilers because it was a familiar fact that on our railways pressures of 150 lb. and more were regularly carried. It is no disparagement of the water-tube boiler to say that the results of its adoption have not been uniformly satisfactory. It is, for one thing, peculiarly exigent in its demands for good water, and in the second it is very expensive to keep clean, and if not kept clean the tubes split and leak. The locomotive boiler, again, is a very admirable steam generator, but it, too, has its peculiarities. It is the full consciousness of these things that has induced millowners to resist all temptation to use any other than the double-flued or Lancashire boiler, which has been recently so proportioned that it will carry any pressure asked for. Indeed, it should be almost self-evident that if a marine boiler 15ft. or 16ft. in diameter can carry a pressure of 160 lb., there ought to be no difficulty in making a Lancashire boiler of half the diameter equally strong. The mistake committed by the electrical engineers has been in assuming that the boiler which made steam most readily, and was most economical in the consumption of coal, must be the best. It is just the species of error into which the non-commercial engineer is likely to fall. The truth is that coal represents but one item in the cost of making steam, and it is not invariably the most important item. The price to be paid for water is not infrequently very large; and even high-priced water may not suit either water-tube or locomotive boilers. Then there is the question of wear and tear, the quality of the steam produced, and many other matters which must all be considered before it is possible to say what is the best type of boiler to put down; and all this, be it noticed, has nothing whatever to do with the qualities of the boiler regarded from the theoretical point of view.

To make our meaning quite clear, let us suppose that a sum of £500 is available for the purchase and erection of a boiler. We may obtain with this a Lancashire boiler which will work well and give satisfaction for ten years, with very moderate repairs, and be nearly as good and serviceable at the end of that time as it was at the beginning; or we may get a locomotive boiler which will need heavy repairs before half that period has elapsed, and will be good for very little at the end of the term. Or a water-tube boiler, which will last for half a century, simply because it has new tubes put in, a few at a time, all the year round, every year of its life. All three may be of equal evaporative efficiency, but even if they were not, the millowner would keep to the Lancashire boiler, not only because it would, in the long run, be much the cheaper of the three, but because it would always be ready when wanted. It would seldom, if ever, be laid off for repairs. No doubt it may be urged, and urged with truth, that both the water-tube and locomotive boilers are excellent steam generators. This does not affect the question in any way. All the experience available goes to show that over a series of years the Lancashire boiler will be found less costly in up-keep, and more trustworthy than any other type of land boiler in the market; and that this truth is gradually coming home to electrical engineers is demonstrated by the circumstance that recourse is now being had to the Lancashire boiler in very important installations, to an extent, indeed, not dreamed of a few years ago—that at St. Pancras, for example, which we illustrate this week. It must be understood that in writing as we do, we are simply bringing before our readers certain considerations often overlooked, and endeavouring to find a cause, if not a reason, for the remarkable departure from normal practice which marked the advent of the electric light in this country. It can scarcely fail to strike any thoughtful man as remarkable that types of boilers scarcely known in Great Britain should have been used to the exclusion of all other types for supplying steam to electric light engines. Outside of railway shops no locomotive type boilers could be found driving stationary engines of more than a comparatively few horse-power. In factories they are practically unknown. The water-tube boiler fought for its life in Great Britain. All over the kingdom, in spinning and weaving mills, pumping stations, factories of all kinds, many rolling mills of the largest size, nothing was used but the Lancashire boiler. But with the new light all this was changed, and we had not only the electrical experiment, but the steam generating experiment as well, and it is not remarkable that the results were not always quite satisfactory.

It would not be fair, however, to attribute the adoption of the locomotive type or the water-tube boiler either to caprice or theoretical knowledge alone. No doubt installations were often constructed under circumstances that rendered it next to impossible to use anything but the water-tube boiler. There are places in the Andes where no part of a steam engine or boiler must weigh more than 200 lb. Everything has to be carried on mule back. There are places in great cities into which it is equally impossible to onvey any large structure. For such places the sectional boiler is simply invaluable. But this scarcely suffices to explain the favour which the locomotive type of boiler enjoys. It is not because only such a boiler can be forced, and other reasons must be found for its adoption. That it requires no brickwork, and is an excellent steam maker, are no doubt points very much indeed in its favour; but, when all this has been said and admitted, we have still to face the fact that for places where large demands are made for steam, day after day, nothing is so popular as the Lancashire boiler, or its modifications.

Those who can read the signs of the times know that the production of electricity on a small scale in numerous establishments will have to give way to its manufacture wholesale, on a great scale. That which has become possible at Beckton with gas may become equally possible with electricity. The question will then force itself on engineers, What is the best method of manufacturing steam? It is not wise to prophecy until after the event. Yet we are rash enough to say that probably the Lancashire boiler will be used in conjunction with mechanical stokers, the smallest possible amount of manual labour being employed. In settling this question it must not be forgotten that the demand for power becomes more and more uniform the larger the installation, and, consequently, the wider the district served. "The peak" does not occur, for instance, in all existing metropolitan installations at the same hour. This consideration will have an important influence on those who have to select the type of boiler to be used. Furthermore, the heat storage system introduced by Mr. Druitt Halpin may modify conditions of service very considerably. In saying this we do not wish, as we have said before, to be understood as finding fault with any particular type of boiler. Our object is to record what may be termed the drift of public opinion. It does not follow that we regard the water-tube boiler as inferior to the Lancashire if we state as a fact that millowners prefer the latter, and that electrical engineers in taking to the former have departed from precedent. The doubt and hesitation which exist are fairly well exemplified on a small scale at Islington, where Mr. Gay has put down both Lancashire and water-tube boilers almost side by side. It must, too, be borne in mind that nearly all the electric light stations in this country are comparatively young, and few opportunities have yet been afforded for testing the actual life of a boiler. Our purpose will have been served if we have succeeded in directing the attention of our readers interested in the manufacture of electricity to the fact that a considerable departure from normal manufacturing practice has marked the progress of the electrical engineer, and that many more things than the production of steam have to be thought of when ordering a boiler.

◆

COMMON SENSE IN WORK AND WAGES.

One feature of the present revival of trade in iron and steel manufacture has not received the attention it deserves. Time was when the very slightest indication of an upward trend in business was sufficient to cause the workers to agitàte for increased wages. The effect was invariably disastrous. If the employers had accepted the contracts on the basis of the existing wages arrangement, they were compelled to carry them out at a loss unless they had been successful in getting the customer to accept what is known as the strike clause. This could not always be done, as in the case of urgent work the contracting firm were obliged to have what they wanted under any circumstances. During the last quarter of a century in the Midland district an enormous amount of work was lost and jeopardised through this rash policy of rushing for an advance the moment the men knew their masters were busy, or likely to be busy. Sometimes the effect was felt in another way. The very mention of a strike or a probable strike in any particular district had the result of causing the customer to go elsewhere. He could not take any risks, and although the manufacturer might tell him that the difficulty would be tided over and the work delivered, yet the belligerent attitude of the unions concerned frequently counterbalanced the employers' assurances. In this way work was lost in many instances—work which in some departments never returned. Our artisans seem to be getting wiser. Although in regard to the coal trade they still vote *en bloc* for whatever their leaders tell them, and are quite content to go on working short time a week at a high rate of wages, the result, however, being less wage at the week-end, it is inspiriting to notice that this imprudent policy finds no favour outside the coalfield. Disputes, more or less serious, have interfered with coal getting and are still interfering, but in the great industries of iron and steel, so far as Central England is concerned, there is practically peace all along the line. The men are beginning to see, taught by a long period of depression, that England, having no longer a monopoly of the world's manufactures, must compete keenly for what is left, and lose not a point in the conflict. It is becoming increasingly evident with them that their masters' interest is their interest, and that in proportion as they can join hands with him in putting finished goods upon the market at prices which will meet their rivals' efforts, precisely in that proportion will they have work with wages to take home during the twelve months. The issue of this sensible course of conduct is clear. The employers are able to take advantage of the prosperity which is now steadily coming towards them. The workmen have faith that, if it continues, and if the value of business rises as well as the volume of it, that they will get their fair share of the flood. In one or two of the lighter industries the manufacturers have already quietly given back to their men the percentages which the men conceded when business was bad. A generous recognition of this sort tells more in the working field than any number of speeches from the glibbest orator. It is to be hoped that this pleasant feature in the iron and steel trades of 1896 may extend and become general, for whatever may be done in the way of scientific development and perfect appliances, the great point, after all, is to have a perfectly harmonious understanding between the workers of England and those who provide them with work. It is, in effect, the pacific alliance of capital and labour that will bring about the industrial regeneration of England quite as much as the most ingenious of machinery or the ablest of management.

THE ELECTRIC LIGHT IN THE PROVINCES.

ELECTRICITY as an illuminating agency is making satisfactory progress in Sheffield. The annual meeting of the shareholders of the Sheffield Electric Light and Power Company, Limited, was held on Monday, when a dividend of 5 per cent. was declared. The Chairman, Alderman George Franklin, in the course of a most interesting speech, narrated the steady growth of the company's business. Just as railway companies worked out their calculations on the basis of train mileage, so, he said, electric light companies calculated their progress by the number of eight-candle power lamps required, and the units of electricity sold. In 1892, there were 7734 lamps wired; in 1893, 8419; in 1894, 15,672; and in 1895, 25,552. The returns in respect of units sold had been equally satisfactory. In 1892, the number of units sold was 91,524; in 1893, 131,752; in 1894, 192,220; and in 1895, 302,965. During the year ending December 31st, 1895, the number of customers had increased from 170 to 249. New customers are still coming in, and no customer supplied with the light had abandoned it. The cost of production is engaging the attention of the directors. As the load increases, the cost, of course, ought to decrease. In 1893 the cost of production and distribution was equal to 5·14d. per unit; in 1894, it was 3·80d.; and last year it was 3·55d. per unit. The cost price, therefore, is a farthing less now than in the previous year. At the present time the company has 25 miles of pipes laid in the streets of Sheffield, representing something like 8½ miles of street frontage. Alderman Franklin, referring to the remarks of Sir Frederick Mappin, chairman of the gas company, said that the shareholders in electric light could have no better testimony to the security of their investment than in Sir Frederick's statement that "the electric light was with them, it was going to stay, and going to increase as gas had done." That was what the Electric Light Company had been telling the public for some years, and it was pleasant to find the gas company realising the fact. Sir Frederick Mappin had told his shareholders that electricity had been with them for some years and was quite unable to stop the increasing demand for gas. Alderman Franklin utilised this statement by telling his shareholders that although gas had been with them for eighty years, it was quite unable to stop the increasing demand for electric light. At the same time, if he were a holder of gas stock he should not be in the least alarmed, for that company had plenty of scope in the two-light meters, and in supplying gas to gas engines, grilling stoves, and other work of that kind. It was certainly a remarkable testimony to the favour with which the new light is being received that in not a single case where it has been put has it been taken out; and that, despite the bright and clear weather experienced this winter, and the absence of fogs, the supply of electricity has increased by 33 per cent. over the corresponding period of last year. The shares of the company are already quoted at a considerable premium, and a further issue now being made is restricted to the present proprietors, who are readily subscribing for them at a considerable premium.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Fleet Engineer Elijah Tricker to the Victory, additional, for the Mercury, to date March 21st. Acting Engineer Henry W. Heyes to the Wallaroo, to date December 23rd, 1895.

LITERATURE.

Attack and Defence. By CAPTAIN MAUDE, late R.E. London: Keliher and Co., 33, King William-street.

THE author in his preface tells us that he writes under the conviction that the friction of increasing trade competition must in time draw us into war, and that war will involve such injury to our ocean-borne trade as will entail suffering such as cannot fall on Russia or even France. He urges that in view of such a contingency England should be prepared to take the offensive, and not merely defend her own shores and commerce.

The first section is on field fortifications and intrenched camps, and covers ground that has been dealt with in similar works. He gives new reasons, however, for the success that has attended the use of irregular rather than permanent fortifications, and his reasoning appears to be good. Naturally the rapid construction of works argues an amount of energy and power in the force undertaking this defence that has not necessarily or generally been found in the troops defending the regular defence of fortresses. One remarkable opinion comes out in this section, and still more in that following it, namely, the evolution of modern drill-books—namely, the writer's conviction that the fire of infantry armed with breech-loading rifles is no more formidable than that of past generations. The writer says, "In Frederick's days the line stood three deep, one man to the pace, and fired six volleys a minute, or twenty-five bullets per yard of front, quite as many, in fact, as a line in single rank can get off to-day." We question this statement altogether, but admit the writer's point that the fire of a line is ruined by a "screen" of skirmishers in front, and go with him in much that he says as to the confidence imparted to men by advancing in an unbroken line. Anything that gives a sense of support should be encouraged. The fact is that in danger, when men's nerves become severely strained, the main difference between old and young troops is that the former instinctively trust to their discipline and habit of keeping together; the latter having not acquired this instinct, are tempted to trust to their legs to get away. There is much that is very interesting in this section, such as Moltke's simile of fording a river, illustrating the task of carrying a position. The author considers that no troops of the present day will bear the strain of heavy loss that was borne successfully by good troops in past generations. Space would not allow us to deal here with the attack or defence, infantry and cavalry attack, and Imperial insurance. We would commend the work to our readers as original and valuable. It is evidently based on much study of the most modern writings and facts. If there is a fault it is that so many issues with different bearings are brought before the reader that the conclusions are sometimes less distinct than could be wished. If this, however, is a fault, it is one on the right side.

Elementary Treatise on Mensuration. By B. T. MOORE, M.A. Second edition. London: George Bell and Sons. 1896.

Elementary Mensuration. By R. H. STEVENS, M.A. London: Macmillan and Co. 1895. 3s. 6d.

MR. MOORE claims that his treatise differs essentially from the usual existing treatises on Mensuration, inasmuch as all the rules and formulas employed in it are strictly demonstrated. Some of these demonstrations are very laboured, because the author wrote at a time when calculus-dodging was in vogue; but the modern technical student is no longer frightened by differentiation and integration. The answers to the examples and problems are not given. This will raise an outcry in the scholastic world; but, on the other hand, the author is doing well by compelling the student to examine his results carefully, and to test them himself by independent considerations, exactly as he would have to do in the real application of mensuration where the answers are not given. Mr. Stevens' book is more of a schoolboy's treatise. Here the answers are always given, however easy the question. The boy turns up the answer, and if his own result is 12, or 144, or 1728 times too great or too small, he knows he has forgotten to turn feet into inches, so he makes the requisite change and feels quite satisfied with himself. But what would his employer say if he brought him such preposterous answers to a real commercial question? The collection of arithmetical results in treatises on mensuration removes all sense of responsibility in the student; on the other hand, the absence of the answers makes the working tenfold more difficult. With this difference, both treatises are well adapted for their special purposes in being provided with abundant and well-chosen examples of every character, as required in surveying, gauging, taking out quantities in earthwork, and in shipbuilding.

SHORT NOTICES.

The Law relating to Factories and Workshops, including Laundries and Docks. Part I. A Practical Guide to the Law and its Administration, by May E. Abraham. Part II. The Acts with Notes, containing the Factory and Workshop Acts, 1878 to 1895; the Shop Hours Acts, 1892 to 1895, &c. With Explanatory Notes by Arthur Llewellyn Davies, of the Inner Temple, Barrister-at-Law; with an Appendix, containing a full list of Special Rules made for dangerous employments, and a complete Index to both parts. London: Eyre and Spottiswoode. 1896. Price 5s.—The incompleteness of the knowledge possessed by the owners of factories and workshops of the law that relates to their property and the operations conducted by them is ample reason for the publication of a book which forms a guide, not only for the use of those practising in this branch of the law, but for those who have to abide by the somewhat numerous Acts concerning it. Our readers are mostly concerned with those parts of these enactments which relate to factories in which machinery of any kind is employed. A very useful feature of this book is the ample reference to cases which have been settled under the several Acts, and which form precedents. We do not find, however, any reference to one or two of the cases in which the judgment had been adverse to the vexatious interference of some of the double-diligent inspectors of factories who have insisted on apparatus and precautions, which have not only been costly additions to machinery, but which have been absolute waste of money, because the machines have been unworkable with these absurd additions. Only recently, for instance, we have observed the uselessness and impracticability of some of these requirements imagined to be necessary by factory inspectors in connection with wood-working machinery. In one case the owners of hand-planing or surfacing machines were requested to fix guards above the cutter spindle. The guards were accordingly ordered, made, paid for, and put on the machines; then the workmen wanted to use the machines, and to enable them to do this the guards were taken off, and will have to remain off so long as the machines are used. Absurd cases of this kind are only too numerous, and it is only because factory owners find it less expensive to pay for these absolutely useless accessories than to waste their time and money in resisting the requirements of the inspectors that the latter are complied with. The knowledge of the several Acts, and of the cases which have been determined under them that can be obtained from this book, will be of great value to the factory owners, and the book will be at least of equal value to those who have to advise on factory and workshop inspection questions.

The Naval Pocket-book. By W. Laird Clowes With plans. Corrected to January 1st, 1896. Addenda to February 1st, 1896. London: Tower Publishing Co., Ltd. 1896. Price 5s. net.—The labour involved in the preparation of this apparently little book must have been very great. It is printed on extremely thin tough paper, and contains no less than 850 pages, besides a considerable number of advertisements, which are, to say the least, superfluous. It may be regarded as not only a concentrated essence of Brassey's "Naval Annual," but as much more. It contains the principal particulars of every warship under the sun, and of many craft which can only be called warships by an extreme display of courtesy. It is illustrated by neat little sketches. In it we find particulars of all the dry docks in the world, knot tables worked out for high speeds, of from 20 to 40 knots inclusive, an almanac and ready reckoner, and a multiplicity of miscellaneous matter. It is really a wonderful little book, just one of those which makes the possessor wonder how he has managed to live so long without it.

Engineering Estimates and Cost Accounts. By Francis G. Burton. Manchester: The Technical Publishing Co., Ltd. 1896. Price 3s. net.—The importance of systematic cost accounts and their value as means of making estimates has been increasingly recognised in the past dozen years, and many firms now spend a good deal of money to secure these advantages, and save the money which would otherwise be wasted. The little book before us will meet the requirements of many who wish to enter upon a proper system of keeping of cost accounts, and as the examples are of a thoroughly practical kind, they increase the value of a book which must teach almost entirely by example. The book is one in a field little occupied, and is one that may be commended.

Electrical Engineering as a Profession. How to enter it, and guide to the Engineering Profession. Official edition. By A. D. Loutham, A. Inst. E.E. With thirty-three plates. London: Loutham and Co. 1896.—This book contains little or no original matter. It is none the less useful. It is simply a guide to the technical schools and colleges in which education can be obtained. It is in this respect very complete and fully illustrated. It is calculated to serve a useful purpose as a book of reference.

THE HORSELESS CARRIAGE BILL.

WE give below the full text of this Bill, which was introduced in the House of Lords on Tuesday last. It will be seen that it is proposed to remove all restrictive enactments from a mechanically-propelled carriage, provided it be under two tons in weight, unloaded, be not employed in traction, and do not discharge smoke or visible vapour. Such a carriage, as might be expected, is to be subject to general regulations applicable to traffic on highways, and Section 26 of the Highways and Locomotives Act, 1878, is to apply. That section confers upon county authorities power to make bye-laws for prohibiting the use in any vehicle, whether drawn by horses or not, of wheels of unsuitable width, or having projecting studs or bars of a pattern forbidden by such regulations, and also for prohibiting the locking of a wheel in descending a hill, unless a shoe be used. We may possibly hear something more about the provisions as to wheels when the Bill gets into Committee. We have always strongly urged the importance of placing the power to make regulations for the use of these carriages in the hands of a central authority, a principle which, except as to the county bye-laws regulating wheels, is, we are glad to see, recognised by the Bill, and the Local Government Board is to be the central authority.

(1) The enactments mentioned in the schedule to this Act, and any other enactment restricting the use of locomotives on highways and contained in any public, general, or local and personal Act in force at the passing of this Act, shall not apply to any vehicle propelled by mechanical power, if it is under two tons in weight unladen, and is not used for the purpose of drawing any other vehicle, and is so constructed that no smoke or visible vapour is emitted therefrom, and vehicles so exempted are in this Act referred to as light locomotives.

Provided as follows:—

(*a*) Nothing in this section shall affect any power for the general regulation of traffic on highways, and a light locomotive is hereby declared to be a carriage within the meaning of the enactments relating to highways;

(*b*) Section 26 of the Highways and Locomotives (Amendment) Act, 1878, and the enactments relating to hackney carriages and stage carriages respectively, shall apply to light locomotives as if they were drawn by animal power, and the said Section 26, as so applied, shall extend to London; and

(*c*) So much of Section 6 of the Locomotives Amendment (Scotland) Act, 1878, and of Section 6 of the Public Health (Ireland) Amendment Act, 1879, as gives power to regulate the use of locomotives shall apply to light locomotives.

(2) The keeping and use of petroleum or of any other inflammable liquid or fuel for the purpose of light locomotives shall be subject to regulations made by a Secretary of State, and regulations so made shall have effect notwithstanding anything in the Petroleum Acts, 1871 to 1881, and breach of any such regulation may, on summary conviction, be punished by a fine not exceeding £2.

(3) If any person negligently drives a light locomotive, or suffers it to be without due control, he shall be liable on summary conviction to a fine not exceeding £10.

(4) The Local Government Board may make regulations with respect to the use of light locomotives on highways, and a breach of any such regulations may be thereby made punishable by a fine not exceeding £10, recoverable on summary conviction.

(5) This Act may be cited as the Locomotives on Highways Act 1896.

SCHEDULE.

Enactments which are not to apply to light locomotives.—The Locomotives Act, 1861 (24 and 25 Vict. c. 70); Section 41 of the Thames Embankment Act, 1862 (25 and 26 Vict. c. 93); the Locomotives Act, 1865 (28 and 29 Vict. c. 83); the Locomotives Amendment (Scotland) Act, 1878 (41 and 42 Vict. c. 58); the Highways and Locomotives (Amendment) Act, 1878 (41 and 42 Vict. c. 77) so much of Section 6 of the Public Health (Ireland) Amendment Act, 1879 (42 and 43 Vict. c. 57), as relates to the hours during which locomotives are not to pass over roads or highways.

SALVAGE APPLIANCES.*

By Mr. J. G. KINGHORN, Member.

THE object of this paper is to draw the attention of the members of the Institution and nautical world to improved appliances for dealing with salvage operations, and supplying a means of grappling with the lifting and floating of stranded and sunken vessels, which, with the present inefficient plant, is in many instances impossible. The Thames Conservancy possess the best lifting camels in existence, and all vessels sunk in their waters are lifted by these camels, and even their plant was, I am informed, taxed to nearly its utmost in lifting the s.s. Durham some months ago. This steamer was estimated to weigh 1400 tons in water. The whole efficiency of the plant of the Thames Conservancy is derived from the rising of the tide, and would therefore be next to useless where there was no rise or fall of water. I will now proceed to describe the patent appliances and the mode of working. To overcome the want of adequate tidal range on some parts of our own and continental coasts, and in the Mediterranean, where there is nearly a total absence of rising water, the winch—Figs. 11, 12, and 13—has been devised, for which the following advantages are claimed:—It will grip a steel wire rope of large size at any given point; it will not injure the rope. It will heave any weight the rope can stand, slowly and steadily; will pay out rapidly, and register the weight borne by the rope on a suitable indicator gauge. It has a revolution counter, and the indications of the weights and revolutions are electrically reproduced by suitable instruments at a common centre, say a bridge-house, on any one of the camels, thus enabling the salvage engineer to have full control of the lifting power at his command, and a perfect knowledge of the strain on each and all of the wire ropes.

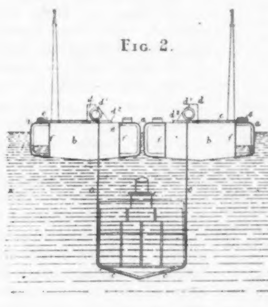
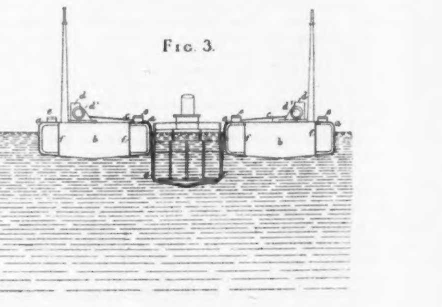
FIG. 2.



SECTION SHEWING VESSEL BEING LIFTED WITH WIRE ROPES OVER SIDES OF CAMELS

FIG. 3.



Now, referring to the drawings, the winch consists as follows:—On the base-plate *a* are two lower frames *b*, and two upper frames *b* 1. These frames support the ends *c* 1 of the hollow winding barrel *c*, on one end of which is a reel *c* 2 by which the unused portion of the rope is carried. The barrel *c* is worked by worm wheels *d* fixed on such barrel, and worms *e* engaging with and driving them; these worms being worked by worm wheels *f* on the shafts *e* 1, driven by worms *d* mounted on the shaft *g* 1, said shaft being rotated by a worm wheel *h* thereon, driven by a worm *i* supported in one of the flanges *b* 1, and driven by the bevel wheels *j* from the shaft *k*; this shaft being revolved by suitable power. When starting, in the lifting action of the winch, little or none of the rope will be on the barrel; while the part connected to the body to be moved would be tight, the remainder being on the reel *c* 2. The rope is passed to the reel *c* 2 from the barrel by way of a hole *c* 3 of gradual curvature, and over two grooved internal guides *c* 4 of suitable curvatures—see Fig. 4—by which, when tension comes upon the ropes, friction is created, and assistance to the holding afforded. Between the guide *c* and the reel *c* 2 there is a wire rope-gripping device *i* of a suitable kind, by which the actual holding and making fast of the rope is effected. From here the rope passes over and is wound loosely on the reel *c* 2, this being the unused portion of the rope. The lead of the rope from the barrel *c* to the reel is nowhere bent or turned at such an angle as to injure the rope; that is, the turns being easy and gentle, the rope cannot possibly be damaged by the gripping in the machine. It will be seen that, as the barrel revolves, the unused portion of the rope revolves with it.

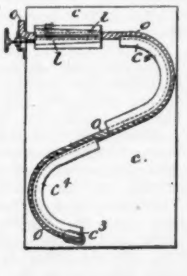
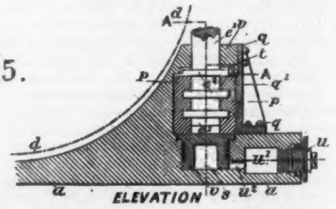
FIG. 14.



HYDRAULIC THRUST BEARING

FIG. 15.



VIEW OF INTERIOR BARREL OF THE WINCH OPENED OUT FLAT

The main driving worms *e* have their shafts *e* 1 vertically mounted, and the lower ends provided with rings *e* 2, fitting in corresponding thrust block grooves in the part *b* 3 of the frames *b*. These blocks take all the strain which comes upon the worm shaft *e* 1. A modification of these supports is illustrated in Figs. 5 and 6; in these the shafts *e* are supported hydraulically, and the pressure on them indicated by an indicator. In the construction shown, the collars *e* 2 work in and are carried on a block *p*, made in halves, and prevented from rotating by a key *q* 1 on the retaining bracket *q*; and the lower end of the shaft *e* 1 and block *p* rest upon a piston *r* working in a cylinder *s* in the bed-plate *a* of the winch. The cylinders *s* are connected together. The shaft *e* is mainly kept in position vertically by the cap *v*, only a small amount of movement is allowed to the shaft *e* 1. The small amount of movement of the piston is governed by the space *t* between the upper ring *e* 2 and the metal above it. The shaft *e* 1 is raised or lowered by a screwed plug *u*, which screws in and out of the cylinder *u* 1, which is connected to the cylinder *s* by a passage *u* 2, and is filled with oil. The pressure on the shaft and piston, and so on the lifting ropes, is indicated by a suitable pressure gauge on the cylinders *s* or *u* 1, showing the weight in tons carried by the winch. By these means the pressure and strain on the two sides and shafts of a winch can be ascertained and regulated, and when several winches are used together for raising a single body of great weight, as when raising a ship, the strain on the different machines acting upon it can be seen at once by means of gauges electrically connected with the bridge-house; also gauges from the gearing on the winches would have electrical connection to gauges in the bridge-house, indicating the number of revolutions performed by each machine, thus enabling the salvage engineer in charge to have complete control of the whole lifting by the machines. The gear between the worms *e* and the motive power is not restricted to that shown, but may be varied according to circumstances; nor is the invention—although the construction shown is a convenient one, and may be used with advantage—restricted to the particular form or arrangement of parts given in these drawings.

I will now proceed to describe the camel. With reference to the drawings, Fig. 1 is a plan; Fig. 2 is a cross-section of the camel or pontoon, and of the ship to be raised; Fig. 3 is a cross-section showing the position of the pontoons for raising a ship not completely submerged, and small submerged vessels can be lifted in deep water in the same manner; Fig. 4 is a plan of a pontoon to a larger scale; and Figs. 5 and 6 are longitudinal sections, and Fig. 7

---

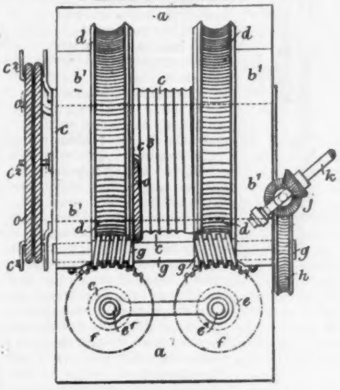
* Read at the Thirty-seventh Session of the Institution of Naval Architects, March 26th, 1896.

a cross-section of pontoon at the lines A A, B B, C C, respectively, in Fig. 4; Fig. 8 is a sectional elevation of the bollards and sluice valves; Fig. 9 is a plan of the sluice valves, and Fig. 10 a cross-section of sluice or section valves and conduit controlled thereby, connected with pumps for emptying and filling the different compartments of the pontoon. On either side of the ship to be raised we employ pontoons *a*, in most cases four, arranged as indicated in Fig. 1. According to this invention, the pontoons are provided with transverse wells *b*, running through two-thirds of the beam of the vessel, by which construction the ropes *c*, by which the vessels are lifted, can be taken up vertically from the ship to and through the pontoons, and a direct pull or strain is put upon the pontoons; and no matter what the width of the sunken ship be, the same set of pontoons can be used, and in all cases the raising ropes can be arranged truly vertically, so as to get a direct pull. And, moreover, with this direct pull the adjacent sides of the pontoons on the opposite side of the wreck do not press or bump against one another, the position of the ropes being so arranged that a sufficient distance between the pontoons is always maintained, which is very desirable. In connection with these wells, and the lifting ropes, winches—as before described—are employed, by which the apparatus is capable of raising wrecks where practically no tide exists. The type of winch used for this purpose is one whereon the ends of the ropes are not carried and held on the winding barrel; but in each case the end is held on a separate reel or barrel, which moves with the winding barrel. This method of stowing and coiling the rope is employed because only one set of coils of the rope can be coiled on the winding drum *d* 1 of the winch, it being impossible to have the coils one upon another for the purpose such as described, where the weights to be raised are enormous, as coils one upon another will damage the rope, and might render it useless for further raising purposes after one use. In the case of the ship being, say, about 2000 tons, and the four pontoons shown be used, each winch and wire rope at each side will carry 100 tons. When the ship is raised by the winches alone, they haul on the rope at both ends equally.

As regards the use of wire ropes, about 10in. or 11in. in circumference, as at present made, is considered the maximum size that can be handled by men under such conditions as wreck-raising; and therefore, practically the limit of weight which can be lifted is in this sense governed by this fact; nevertheless, the weight which may be lifted will vary accordingly as more or less ropes are placed under a ship, and the pontoons are made larger or smaller. When the ropes *c* do not pass directly through the centre of the wells *b*, the water tanks of the pontoons on the side on which the lesser strain comes are partly filled with water to keep the pontoons on an even level.

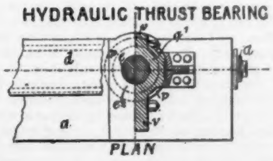
PLAN OF WINCH

FIG. 13



HYDRAULIC THRUST BEARING

FIG. 16.



When lifting ships which are not completely or deeply submerged by means of winches, the pontoons are placed as in Fig. 3, and the winches are placed on the off-side of the pontoon, to counterbalance the weight which comes upon the near side, and, if this is not sufficient, the outside compartments of the pontoons are partially filled with water. The bollards—see Figs. 4, 8, and 9—consist of large hollow steel cylinders *e*—4ft. in diameter—angle plates *e* 1 riveted to the deck and to *e*, and brackets *e* 2 riveted to the deck and to *e* and *e* 1; and they are arranged in pairs as usual, one being on each side of the bulkheads *h*. At the edge of the pontoons over which the ropes would be passed, in cases as shown in Fig. 3, suitable rollers are provided to ease the movement of the rope over the bend. The position of the winding barrel *d* 1 of the winches *d*—see winch in Fig. 4—is directly over the wells *b*, *d* 2 are bed-plated on the winches. The winches are moved as desired over the wells B, and suitable provision is made to secure them in any required position, so that the lifting ropes from them are vertical and the adjacent sides of the pontoons will not touch in the lifting operations.

Regarding the pontoons, they have a longitudinal bulkhead *f* at either side and transverse bulkheads *h* running between the ends of the wells and vessel's sides, forming the side chambers into a number of compartments, and strength is given the vessel where the lifting ropes go over the side, when lifting, as in Fig. 3. These compartments are filled and emptied as required for balancing and manipulating in the raising operations by pumps *k*—Fig. 4—through hollow box kelsons *i*, running through the vessel, and valves *j* in the kelson in each compartment. The pump discharge pipes *k* 2 and inlet pipes *k* 1 are both taken overboard on deck. The chambers between the bulkheads *f* and wells *b*, except those at the bow and stern, are used as engine, pump and boiler rooms, and men's quarters, or other purposes; while those at the ends can be filled or emptied to raise or lower either end of the vessel. The floor at the bow of the pontoons is curved up as shown, and the bow chambers are empty, and the *k* stern ones partly filled with water or salvage gear when being towed. Each valve *j* is opened and closed by a rotatable rod *j* 2, the actuating wheel of which is disposed within the hollow bollard *e*. The valve seat *j* 1 is on the bottom of the kelson *i*, and a trunk *j* 4 extends from it to empty compartments as far as required. In the cover *j* 6 over the valves *j* is a stuffing-box *j* 5. A valve *j* is provided at each end of the compartments to obtain full flow of water, and to pump the compartments dry if the pontoons are tilted.

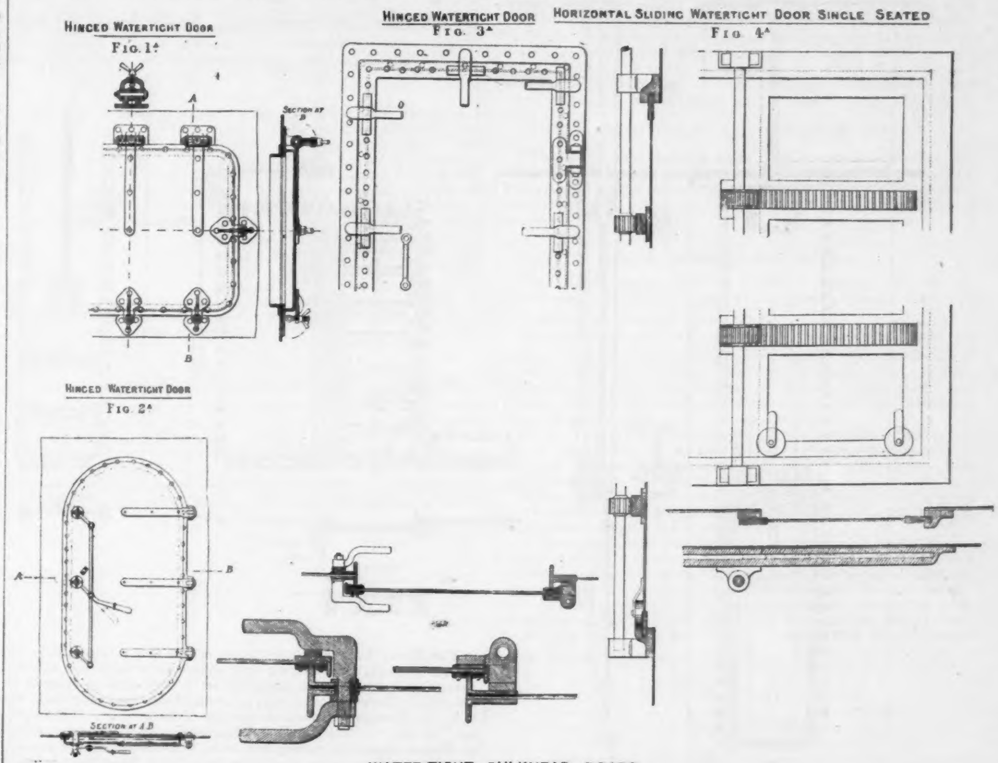
In conclusion, the proposed working of these inventions may be briefly described as follows:—The wire ropes are swept under the hull of the sunken vessel in the ordinary way, by small steamers, or by divers, the ends secured to the masts, if above water, or marked by buoys, until a sufficient number have been passed under the vessel. The camels would then be towed out and arranged in pairs, to the number required, according to the length or weight of the vessel. The end of the wire hawser would be passed on the winches, which have been placed, according to the beam of the sunken vessel, either up through the transverse wells, if a direct vertical pull is necessary, or over the rollers at the sides if otherwise, and, having been hove tight, are then secured in the compressors and the spare wire coiled on the carriers. The winches are then set in motion—the engineer in charge, having his gauges before him, regulates the speed of each winch and the weight it carries—and slowly lift the sunken vessel from the bottom until the winding reels are full. The amount of rope capacity in the winch described being about thirteen fathoms, this being the limit necessary to correspond to the width of the wells, and to ensure against any waste of force, owing to the ropes getting too much out of the perpendicular. In cases where the depths exceed thirteen fathoms, the camels with their burthen would be towed away to a place where the vessel could be safely beached, or if the distance to be towed presented serious difficulties, other ropes could be passed under the vessel and made fast to the bollards on the camels to take the weight, while the lifting ropes were regulated for a fresh heave, and so on until the sunken craft was hove close under, or up between the camels.

WATER-TIGHT DOORS.*

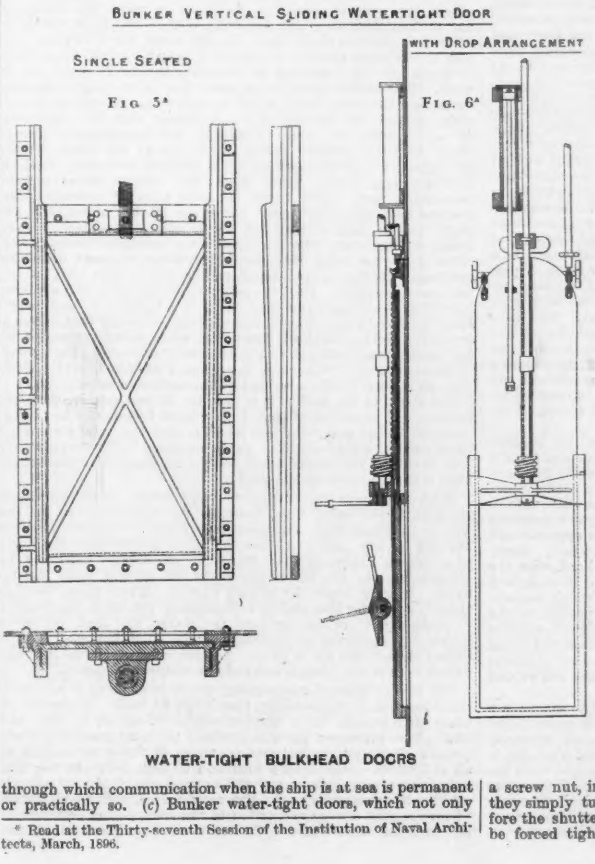
By Colonel N. SOLIANI, Director of Naval Construction, Royal Italian Navy, Member.

WATER-TIGHT doors may be divided into three classes:—(*a*) Water-tight doors, at or below water-line, which, in a sea-way, can be kept always completely shut, or if needed open it is only occasionally and for a short time, after which the doors can be restored to their shut up position. Water-tight doors well above water-line. (*b*) Water-tight doors below water-line, between compartments, such as the engines and boiler-room compartments, through which communication when the ship is at sea is permanent or practically so. (*c*) Bunker water-tight doors, which not only are to be kept open in a sea-way, but are also liable to be jammed by coal when closing.

Hinged water-tight doors.—Water-tight doors under head (*a*) do not require to close quickly, and therefore are usually made hinged, in which form a good, simple, light, and efficient water-tight door can be obtained. Figs. 1, 2, 3 show how these doors are generally made. The hinged door has all round its edge screw or lever latches to keep the door when shut well tight against the seat frame. For bunkers above protective decks screw latches are preferred, all independent and worked only from one side, as in Fig. 1. The seat frame is generally fitted with india-rubber or tuck packing, but when absolute tightness is not necessary, as is the case with coal bunker bulkheads above protective decks, or with doors well high above water-line, the packing can be dispensed with, the seat being then a simple solid frame of rectangular section, as shown in Fig. 2. These solid frames, while efficient, are economical, as they dispense with the packing, which is expensive and subject to rapid deterioration. Various packings, other than india-rubber or tuck packings, such as cotton packing in a natural condition, or well greased leather, &c., have been tried; but, so far, none of them have yet been found to combine durability, efficiency, and cheapness in the desired degree. Doors in passages through bulkheads have lever latches, workable from both sides, as in Figs. 2 and 3. These latches, when the doors are well above water-line—as passage doors on main decks—may be fitted only along the edge opposite to the hinges, and connected all to one handle, in which way they can be worked together at one time—Fig. 2. Latchless doors have also been resorted to. In this case they are double, viz., they have two shutters working opposite one to the other on the two sides of the bulkhead, so that whichever side is flooded there is always one of the two shutters pressed to close by the pressure of the water itself. Suitable springs cause both shutters to close when released after having been opened. These doors are said to be handy and efficient.



WATER-TIGHT BULKHEAD DOORS



WATER-TIGHT BULKHEAD DOORS

Sliding water-tight doors.—Water-tight doors under head (*b*) require efficiency and quickness combined. Therefore, they are usually made of the sliding form, and workable both from the door itself and from the decks above. Fig. 4 shows an ordinary horizontal sliding door, as usually fitted on board ships. The lower side of the door frames of sliding doors, when grooved to form a guide to the shutter, is liable to get chocked with dirt, and to prevent this the guide is usually covered with a lid, which opens automatically when the door is closed. To avoid the necessity of this cover, the lower side has generally no guide. If we turn a horizontal sliding door 90 deg. on its plan, we have a vertical sliding door needing no alteration for its working. However, with vertical sliding, the gear, instead of a rack and pinion, is generally a fixed vertical screw shaft working in a nut attached to the door—Fig. 5. With this arrangement the movement of the door is slow both when opening and closing. Such slowness is not convenient, especially when closing, which operation, in time of emergency, ought to be as quick as possible. To secure this result various devices have been resorted to, a usual one being an excentric or some similar apparatus by which the nut is thrown out of gear when the door is to be shut. Then the shutter falls down quickly by its own weight—Fig. 6. This implies, of course, that the door is closing when the shutter is lowered, as is generally the case.

The disengaging gear, as above described, is open to two objections:—(1) When released it leaves the door free to fall suddenly, and gives no means of checking or regulating the descent; therefore it is dangerous, as the door may be released just at the moment a person is passing through. (2) When the shutter is down it is sometimes not easy to put the nut in gear again to force the shutter well against the seat frame. To avoid these defects, in lieu of the nut a brake is fitted to the door, as in Fig. 6, or two worm wheels with locking brake are fitted, embracing the screw shaft—Fig. 7. These wheels are locked fast when the shutter is raised, but can be made loose at any convenient degree when the shutter is lowered. When locked they act like a screw nut, in which a screw shaft is revolving. When loose, they simply turn freely and glide along the screw shaft. Therefore the shutter can be regulated at will on its descent, and can be forced tight against the seat, when down, by simply tightening the locking brake when the screw shaft can be used to force the shutter.

---

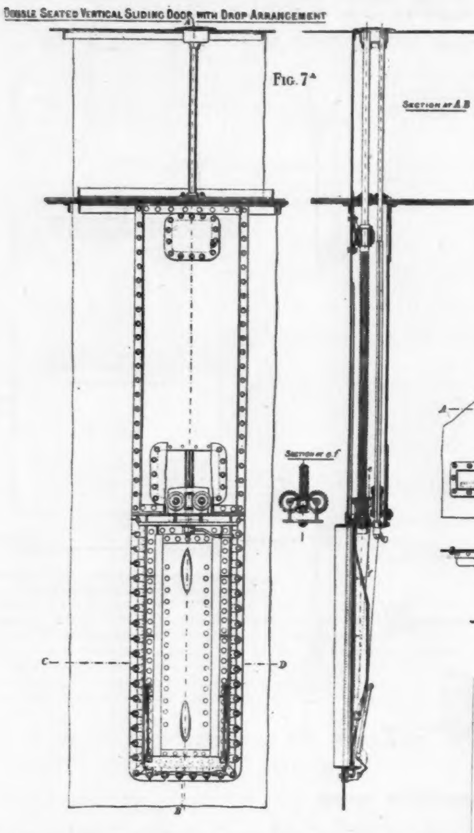
* Read at the Thirty-seventh Session of the Institution of Naval Architects, March, 1896.

The tightening brake can be locked both from below and from above deck, as convenient. The gear, whether rack and pinion or screw shaft and screw nut, is usually worked by hand; but now that electric power is generally available on board ships, the said manœuvre can easily be made by a small electric motor fitted to the hand shaft of each door, as shown in dotted lines on Fig. 8. This arrangement, which has already been fitted on board ships of the U.S. Navy, has two advantages. (1) The door can be opened and shut instantly by the person who wants to pass through, simply by making and reversing an electric contact. (2) The closing of all doors that might happen to be open in time of emergency can be effected by a single person—by the officer in command on the bridge. The electric arrangement does not impair the efficiency of the hand gear—which is needed all the same, should the electric current fail—as, when the electric current is interrupted, the electric motor offers but little friction, which can easily be overcome by the hand gear itself.

Possibly the same advantages might be secured in a more reliable and efficient way by using hydraulic instead of electric power. A simple, small, hydraulic cylinder, with reversing valve fitted to each sliding door, and connected to a pipe carrying the compressed water, would be all that is necessary. The force for working a water-tight door being comparatively small, a small quantity of water at a very moderate pressure, such as is available on the feed pipes of the boilers of the ship, would be sufficient for the purpose. And, as in a sea-way the feed pumps are always at work, the feed water pressure for working the water-tight door would be always available and ready.

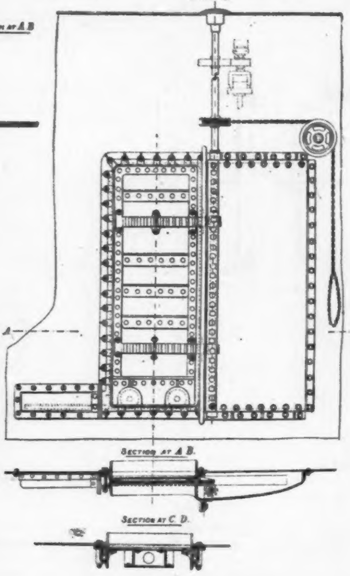
DOUBLE SEATED VERTICAL SLIDING DOOR WITH DROP ARRANGEMENT

FIG. 7A

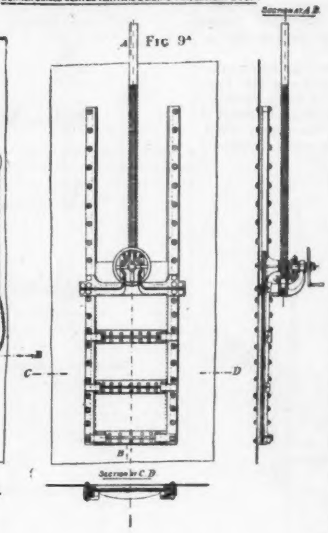


DOUBLE SEATED HORIZONTAL SLIDING WATERTIGHT DOOR

FIG. 8A



BUNKER SINGLE SEATED VERTICAL SLIDING WATERTIGHT DOOR.



The advantages above enumerated are, in my opinion, worth consideration. In fact, why are water-tight doors objectionable? Principally because they are kept open. And why are they kept open? Simply because the operation of opening and closing them is tedious and slow and fatiguing. Reverse this condition, give the man who wants to pass quickly through a door the means of opening it rapidly by simply pulling a small lever, let the lever, as soon as it is released, go back automatically and close the door after the man has passed, and then, I think, you will see the sliding water-tight doors fulfilling their important function of allowing a free communication between the main compartments of a ship, without impairing the safety of the ship. This refers to passage water-tight doors. For bunker doors, which are necessarily kept open at sea, the difficulty would also be overcome by the hydraulic arrangement, as by handling a simple main valve the officer in command would be able to close, in a few seconds, all water-tight doors that might be open at the time. A difficulty would still exist, to a certain extent, on board warships, where the bunker holes on protective decks are kept shut. In these ships the coal trimmers, on closing the doors, would be practically shut in the bunkers with no possibility of escape; a condition not very pleasant. And it is this fear of being so imprisoned that has prevented the success of all schemes for suddenly closing bunker doors, as the coal trimmers, to avoid such an awful fate, contrive means for jamming the doors to prevent them being shut. Therefore, should any arrangement for closing suddenly the bunker doors be resorted to, it ought to be completed by giving proper means of escape to the coal trimmers.

The sliding shutters of water-tight doors, whether for bunkers or for passage through compartments, when shut are usually forced and kept tight against the seat of the door by means of inclined guides or wedges. This arrangement is open to objections, as the wedges are needless when the pressure of the water acts to keep the shutter self-tight against the seat, and they are generally inefficient when the water pressure acting on the opposite side tends to force out and detach the shutter from the seat. Moreover, the guide wedges, to be efficient, must press hard, with the result that the door is then hard to open. To avoid these defects double-seat water-tight doors may be resorted to, which are self-tight, whichever of the two sides of the door is pressed by the water. Figs. 7 and 8 show two double-seat water-tight doors, one vertical and one horizontal sliding, as fitted on board the Royal Italian cruiser Elba. Figs. 10, 11, and 12 show the same principle carried out for bunker water-tight doors, of which more will be said hereafter.

Bunker water-tight doors.—Bunker water-tight doors are generally vertical sliding, single-seated, screw-shaft geared, and close as usual, downwards—Fig. 9. These doors are generally acknowledged to be defective, on account of the coal that lies on their threshold when open and which opposes an obstacle when the shutter is lowered to shut. Moreover, the pressure of the water inside the flooded bunker tends to open the door, which therefore is scarcely water-tight, specially at the bottom, where there are no wedges or guides to keep the shutter well pressed against it. Both objections would, in my opinion, disappear if the door be made double-seated and close upwards, as then it will always be self-tight, whichever side of the bulkhead is flooded; and the coal that might lie on the threshold would fall down by itself in the stokehold or in the bunker when the shutter is being raised.

The author showed a working model of such a door. As will be seen, the door is double-seated and closes upwards, the shutter, when the door is opened, being lodged in a box at the bottom, and filling with its upper edge the threshold groove. Nay, this upper edge forms the bottom of a frame cast solid with the shutter, and which fills the grooves of the door all round, and keeps them clear.

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

THE HAMPSON LIQUID OXYGEN PROCESS.

SIR,—On Saturday Dr. Hampson, at Brin's Oxygen Works, Westminster, gave a demonstration of his process. He produced liquid oxygen without the aid of any cooling material whatever, save some water from the street main; and liquid air, with the assistance of a small quantity of powdered ice and salt. He delivered, I am informed, a little lecture explaining his process. Ostensibly the process is the same as Dr. Linde's, which has been fully described in THE ENGINEER. As to the name of the first inventor, it is not for me to speak. Indeed, my sole object in writing now is, with your permission, to call attention to a very curious episode in Saturday's proceedings. I refer to a remarkable argument made use of by Dr. Hampson to prove the novelty of the process. "Here you see," he said, "a very simple and inexpensive little apparatus, doing all that an apparatus costing hundreds, if not thousands, of pounds can effect. Many men of science have been labouring for years at the liquefaction of gases. If they had invented any such process as mine, is it not certain that they would have used it? Professor Dewar and the continental scientists knew nothing of this process of mine, or assuredly they would have used it." This is a very powerful, indeed conclusive argument. The point to which I wish to direct attention is that no doubt Professor Dewar and others were quite familiar with the facts on which Dr. Hampson has worked, but they did not believe that the facts could be utilised to produce liquid gas. In one word, the Hampson process or the Linde process, whichever it may be called, apparently is opposed to the teachings of thermodynamics. It ought not to work. The more carefully a man has been taught thermodynamics, the more likely is he to regard the process as impossible; and at this moment it is not certain that Dr. Hampson, to say nothing of those present at his experiments, understood why the process works. It is one of the great defects of dogmatic science teaching that it stops progress. Certain laws are laid down. From these the teacher draws certain deductions, and backs them up with piles of formulæ. He teaches that these deductions cover the whole ground, and his pupils believe him, and do not try to advance further. A man comes on the scene who possesses some scientific training, but either it has not been dogmatic, or he refuses to accept dogmatic teaching. He has an open mind, and he quietly does what he was told was impossible. Then the professor comes along and explains how it has been done, and that there is nothing new, and so on. Here we have a man who is not a professor doing that which a number of the best trained men in the world never attempted to do, because they believed that it was really opposed to the laws of thermodynamics. What was the ground of this belief? With your permission I will endeavour to answer it very briefly.

The object of the process is to produce intense cold by the compression and expansion of air. I must insist first on one fact being accepted before going further, which is that the total amount of energy in any given weight of gas is measured by its temperature, and, of course, its specific heat; but for my purpose at present we have nothing to do with specific heat.

If we compress a gas we raise its temperature. If by any means the heat is prevented from accumulating, the energy in the gas will be the same after compression as before. The usual way of drawing off the heat is to allow the air to pass through the tubes of a surface condenser; the whole of the energy expended in compressing the air will re-appear in the cooling water, but no more. It is necessary to be very explicit on this point, because there is a popular idea that in refrigerating machines the heat is "squeezed out" of the air into the water, and that the air is cooled in consequence. Nothing of the kind happens. As a matter-of-fact the air is rather warmer after it leaves the condenser than it was when it entered the compression pump.

The whole object of compressing the air is to bring it into such relations with its surroundings that it can do work. There are so many foot-pounds in a hundredweight of air at 62 deg. and atmosphere pressure; there is precisely the same number of foot-pounds of energy, no less and no more, in the same weight of air at 2000 lb. on the square inch and 62 deg. Fah. In the first case, it was impossible to get the energy out of the air without altering its environment. In the second case, without alteration of environment a large proportion of the energy can be got out of it, converted into work, and the result will be a great fall in temperature; but there can be no fall in temperature unless there is a loss of energy, and there can be no loss of energy unless heat is abstracted or external work is done.

Now, in the Hampson apparatus air is compressed and expanded, and a very small amount of reflection will show that no energy can escape from the apparatus. We have seen that none of the intrinsic energy of the air is carried off by the cold water. It is obvious that no heat can escape from the apparatus. It is most carefully felted and protected to prevent external heat from getting in. It is clear that no external work of any kind is done. Under these circumstances it is self-evident that no energy can get out of the apparatus, and that no cooling can take place. All this is perfectly sound thermodynamics. There is no flaw anywhere. No wonder, then, that neither Professor Dewar, nor Mr. Oselewsky, nor anyone else steeped in thermodynamic lore could originate such an apparatus, an apparatus all wrong from first to last.

But Schröefer showed last year that an apparatus from which there was no perceptible mode of escape for energy could work, and to explain how we are told that it is all due to what is known as the Joule effect. Joule found that when air is allowed to expand slowly and steadily through a small orifice it is slightly cooled, when hydrogen is so treated it is slightly heated. Scientists availed themselves of this fact, or assumed fact—for the experimental investigation is extremely delicate, and very open to error—and said that this is the reason the Linde process works. As a matter of fact, however, the Joule effect is quite unnecessary, while its amount is so insignificant that months, if not years, would be expended in making a quart of liquid oxygen by its aid.

The true theory of the Hampson process is very curious. In point of fact there is no loss of energy or heat from the apparatus at all as a whole, but there is brought about a peculiar distribution of energy within it. To make this clear let us suppose that we have a tube 10ft. long filled with air at 62 deg. The intrinsic energy of the tube and its contents is, say, 500 foot-pounds. Now we can fancy a means provided by which the temperature of the air at one end of the tube will be 500 deg. Fah., and at the other end zero, the intrinsic energy of the whole remaining unaltered. This is what Dr. Hampson and Dr. Linde do. They take a given weight of air at, say, 1500 lb. on the square inch, and they alter the distribution of energy in it. We have the oxygen at a high temperature in the compressing pump, and we have it at −180 deg. say, in the glass receiver, in which the liquid oxygen is collected, but at any given minute during the working of the process the total energy, the total heat in the apparatus, is the same as at any other minute. There is no change of energy until we stop the machine, and take out the beaker of liquid gas.

The cooling is produced not by Joule's effect at all, but by the expansion of the compressed gas in a way so well understood that it needs no explanation. The gas on expanding does work, and is cooled, but all the heat is restored again. In Clark-Maxwell's words, "The sum of the intrinsic energy and the product of the volume and the pressure, remain the same after passing through the orifice, provided no heat is lost or gained from external sources."

In the Hampson apparatus the temperature is lost in one part of it and restored in another, and the continual flow of the cooled gas to the hot pump evidently powerfully tends to prevent the transmission of heat from the hot end of the apparatus to the cold end. It is clear now, I hope, that Mr. Hampson may take any given weight of oxygen and convert a portion of it into a liquid, and yet never abstract any heat at all from the apparatus. All that he does is to localise cold in one place and heat in another. No heat whatever is taken out of the gas as a whole. Indeed, it may be shown that as we go on liquefying portions of the gas, the remainder may become hotter and hotter by the accumulation in it of the heat given up by the portion liquefied. It may be that this rise in temperature would under certain conditions be carried off by the cooling water, but such conditions never occur in practice; the weight of liquid present at any one time being comparatively small as compared with the weight of air, because the process is continuous.

We see here that, arguing on a thermodynamic basis, it is, first, impossible for any energy or heat to escape from the apparatus; secondly, if no heat escapes then no cooling can be produced; thirdly, therefore, an apparatus from which no heat escapes will not produce liquid gas; fourthly, it would be waste of time to attempt to produce liquid gas in this way. Such, no doubt, was the reasoning of any well-grounded dogmatic man of science. Dr. Hampson says in effect: "All this is perfectly true. But its truth is nothing to the purpose. It is possible to make a machine in which by 'regenerative' or 'degenerative' action I can localise all the heat at one end of a tube and all the cold at the other end, and I can make the cold end cold enough to give me liquid oxygen."

The process must not be confounded with that of the Giffard or other refrigerating machines, because in them the air to be cooled does external work, and so there is a direct loss of energy from the apparatus. The principle is apparently the same; it is actually quite different.

Finally, I have only to direct attention to the fact that the thermodynamic laws are not affected in any way; only Professor Dewar and others limited their application, and so missed inventing an exceedingly beautiful process. ZERO.

Westminster, March 23rd.

TRIPLE CYLINDER LOCOMOTIVES.

SIR,—In your leader of the 13th inst. you place before your readers suggestions for a new type of engine to cope with the anticipated and ever increasing heavy traffic of the future, which deserve very careful consideration. It has always been apparent to me that for working fast trains, the speed and weight of which are constantly being augmented, an engine of either the Webb type, or one constructed on similar lines, will have to be employed. It will, I think, be generally conceded that the cylinder capacity of simple locomotives will soon reach its limit—if, indeed, this is not already the case—and for this reason, if for no other, the adoption of the three-cylinder plan will be almost imperative. Following the same reasoning, it is not too much to say that compounding will also become expedient, since it will be practically impossible to have a boiler sufficiently large to supply live steam to three cylinders. Taking, therefore, the locomotive of the future to be of the compound type, and the conditions of working in every way suitable, there seems no valid reason why, even at the present time, such engines should not be used on all lines where heavy loads and long runs are the principal factors to be considered. In other words, there is no reason why there should not be compound locomotives for the heavy express work, just as there are goods engines for goods trains and tank locomotives for slow and intermittent traffic. Seeing that the Webb compounds are equal to taking loads of 300 tons and over without assistance at an average speed of fifty miles an hour, it is difficult to see in what manner these engines have been as unsuccessful as is popularly supposed.

Much has been said at various times as to the additional first cost of a three-cylinder compound and the extra expense of up-keep, but when by the use of such powerful locomotives double engine running is reduced to a minimum, it is surely more economical and satisfactory to use three sets of motion than to employ a pilot, whereby there is the wear and tear of four sets of motion and two boilers. Double fuel consumption and the wages of the extra men must also be taken into account. The cost of running is in every way increased; it is wholly unsatisfactory, and often dangerous. While one engine is inadequate, it generally happens that the pilot and train engine are together more than sufficient for the work to be done.

The great feature of the engine you sketch, as with Mr. Webb's compounds, is the elimination of coupling-rods, not only because a larger fire-box can be got in, but because an exceedingly powerful locomotive, adapted to all the requirements of a coupled engine combined with the advantages of a single, is secured. The success obtained with the Webb type so far has clearly proved to my mind the superiority of the three-cylinder over the two-cylinder plan of compounding. It is, therefore, perfectly reasonable to assume that engines on much the same lines will in the future be found to be the most powerful and, in proportion to the extra work done, the most economical. If so, judging by what has already been done by the Webb engines, the prejudice and apathy which at present seem to stand in the way of a fuller development of the compound principle should be removed. F. W. BREWER.

London, N., March 21st.

SIR,—A compound locomotive designed by M. Jules Morandiere, having three cylinders—one inside the frames and two outside—the inside cylinder being high-pressure and the outside low-pressure, the high and low-pressure cylinders being arranged to drive independent axles, was illustrated in your contemporary, *Engineering*, in the year 1866, that is, thirty years ago. Your correspondent, Mr. Smith, calls it his system; so it would be interesting to learn where his system was previously described.

I quite agree with your contributor as to this being the rational system of constructing a compound locomotive, but would at the same time point out that the simple engine has not been developed completely in regard to its economical capabilities. On the Paris and Orleans Railway are seventeen locomotives fitted with Corliss valves, one at each cover of the cylinder, the two upper valves being for admission and the lower ones for exhaust. The admission valves are worked in a semi-independent manner by the same link motion as works the exhaust valves, the result being that, compared with similar engines fitted with the ordinary slide valve, a saving of 15 per cent. in fuel is obtained, which is quite as much as compounding at present gives. If this construction of cylinder was used for the high-pressure of a compound, I have no doubt that another 10 per cent. would be obtained, while at the same time the engine would be enabled to deal with any range of loads or speeds required—a feature at present impossible. I might add that no complicated trip gears or accessories of that nature are used on the engines I mention. J. DUNLOP.

206, Gorton-lane, Gorton, Manchester,
March 23rd.

SIR,—I have perused your able article in your issue of March 13th, on "Triple Cylinder Locomotives," with the greatest interest, and it has once more brought an idea to my mind which first struck me on reading Mr. Rous-Marten's description of his ride on the foot-plate of Mr. Webb's Greater Britain, which appeared in THE ENGINEER of August 25th, 1893. I was particularly impressed by his remarks on the fine steaming qualities of the long boiler, with its combustion chamber. It appeared to me then that for express engines of the most powerful type this long boiler was the right thing, and I am still of that opinion so long as a combustion chamber is used, as it seems to stand to reason that fuller use of the products of combustion is made with a boiler like Mr. Webb's than is possible with the ordinary short boiler.

Now, if a three-cylinder compound locomotive were built on the lines you laid down, with the long fire-grate and bogie, I would suggest the long boiler also.

There is a large waste space in front of the smoke-box on all bogie engines, and why should it not be utilised? I would bring the smoke-box forward to the same position with regard to the buffer beam that it occupies on an engine with only one pair of leading wheels, and lengthen the boiler barrel proportionately. The high-pressure cylinder would remain in the position you suggest, over the centre of bogie as usual, and the alteration would only mean that it would be outside the smoke-box casing as well as the two outside low-pressure cylinders—which would be so in any case—and that all three cylinders were somewhat further from the smoke-box than usual. There are some objections to this, I am well aware, but none that would seriously trouble locomotive designers; and on the other hand, any necessity for a boiler of undue diameter would be removed. I think by embodying such a boiler in the engine you sketch out, we should arrive at something very near the ideal of a powerful express locomotive.

Springfield, Coventry, March 18th. H. W. STANER.

ENGINE POWER IN PADDLE STEAMERS.

SIR,—The old and new Flushing-Queenborough boats have, it is true, been engined at the same works, but there exists a wide difference between the systems of the paddle-wheels which have been adopted for the two. The excellent old boats have, as shown in the following table, compared to the power, large wheels, while the new boats have small wheels.

	Old boats.	New boats.
D, eff. diameter of wheels	20ft.	18ft. 6in.
Number of floats	10	9
Length of floats	12ft.	12ft. 9in.
Breadth of floats	4ft. 2in.	4ft. 10½in.
A, area of one float	50 square feet	62·34 square feet
I.H.P. (actual)	3543	9000
I.H.P. (intended)	—	7000
$\frac{\text{I.H.P.}}{\text{D.A.}}$	0·282	0·165 and 0·128

Small as the relation $\frac{\text{I.H.P.}}{\text{D.A}}$ is in the new boats, it was originally even still smaller. The result was as might have been expected; at her first trial the first new vessel was unable to keep the stipulated speed, although the engines ran away with the small wheels, actually exhausting all the steam which the boilers could supply. Doubt about the boiler capacity arose; fortunately the propeller question was also examined into; at first it was thought that the enormous slip which had been observed was due to the wheels working in a hollow of the deep wave which the hull raised at great speed. But instantaneous photographs of the vessel under way did not confirm this idea.

Enlargement of the wheels, as far as practicable, was then resorted to; by successive additions the floats were increased up to their present size, the largest which the paddle-boxes would allow to pass. This makeshift was so far successful, that the boats were at length accepted, and are in service, giving much satisfaction in a nautical way. With wheels more in accordance than the actual ones, with the practice followed in the older boats, the same good results could, however, have been obtained with much less slip, *i.e.*, much less power and much less consumption of coal. J. M.

March 24th.

PERMANENT WAY.

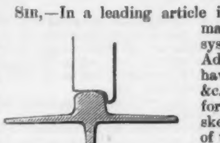
SIR,—In your editorial of 20th inst., the gist of the recent discussion is very properly summed up in the question, "What is the road of least resistance?" and, in effect, you answer it by indicating that the road of least resistance is—*cæteris paribus*—the road with the stiffest rails. That, however, is qualified by saying that "an absolutely rigid road would be intolerable to passengers."

I venture to think that if a road could be constructed absolutely rigid, and also absolutely even and uniform, it would be not only tolerable but perfect. Of course, neither condition is possible in practice. Unevenness causes shocks between the wheel tires and the rails, and the resulting vibrations have to be absorbed by some suitable material as near their origin as possible. The Mansell wheel seems admirably adapted for the purpose as far as rolling stock is concerned, and the evil of these vibrations is incomparably greater to the rolling stock than to the track. As regards the track, evenness and uniformity are of the first importance, and it is a pity that the advantages possessed by the longitudinal system in this way are over-balanced by other considerations. However, with a cross-sleepered road and high speeds, there is scarcely any appreciable shock as the wheels pass successive chairs, providing a sufficiently rigid rail is used, and the line properly ballasted and packed.

Every one who has seriously considered the subject must be of your opinion that too little attention is given to ballast. With bad ballast it is impossible to preserve a good and reliable track, however much labour may be expended upon it. You, Sir, have placed monetary advantages at a lower level than I should have assigned for them, but, in any case, I believe it would pay to lead good ballast long distances rather than employ local rubbish. What is called the "elasticity" of the road, as well as its stability, depends mainly on the ballast; and perhaps I may ask you at some future time to allow me to express in your columns my ideas in this connection.

As you have remarked, the subject is one of permanent interest, and it will remain so until some concerted effort is made by both scientific and practical men to solve it. There have been opportunities for observing and recording the behaviour of permanent way under all sorts of conditions in this country, but, as far as I know, they have not been pursued in any systematic way. Probably your columns afford the best medium for exchanging the data of experience and the deductions of science, and I hope that is this behalf THE ENGINEER may do more in the future than the Board of Trade has done in the past. JAMES WHITESTONE.

113, Queen Victoria-street, E.C., March 24th.

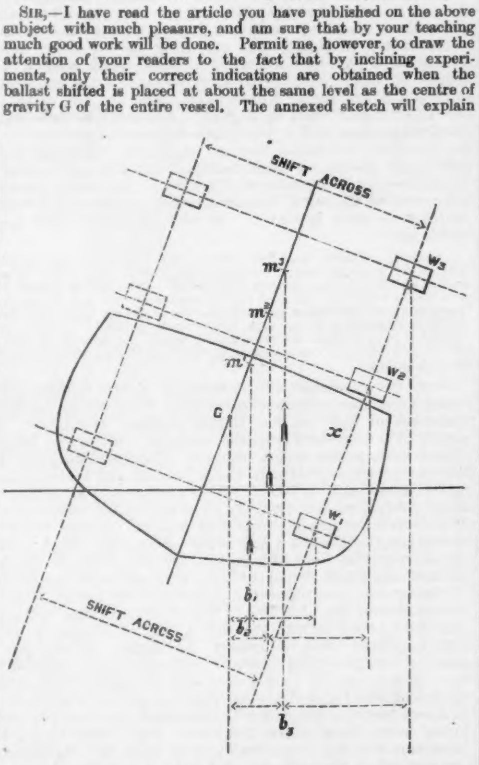


SIR,—In a leading article in to-day's ENGINEER reference is made to W. Bridges Adams and his system of permanent way. Mr. Adams at different times appears to have introduced various types of rails, &c. In 1853 he patented a girder rail for use without sleepers; I enclose a sketch of this rail in section. Width of tread, 2¼in.; total depth from top of rail to bottom of keel, 8in.; horizontal bearing surface on ballast, 14in. It will be interesting to know if a railway were ever laid out with this rail, and if so, the results of the experiment. Perhaps some of your readers can give particulars. G. A. SEKON.

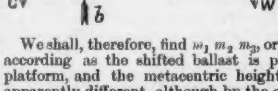
March 20th.

NAVAL ARCHITECTURE—NO. IV., STABILITY (INCLINING).

SIR,—I have read the article you have published on the above subject with much pleasure, and am sure that by your teaching much good work will be done. Permit me, however, to draw the attention of your readers to the fact that by inclining experiments, only their correct indications are obtained when the ballast shifted is placed at about the same level as the centre of gravity G of the entire vessel. The annexed sketch will explain



the point I allude to. W_1 W_2 and W_3 shall be three different positions of the ballast trimmed to one side, in three experiments. The shift across shall be in all three cases alike. G is the centre of gravity of the ship minus the shifted ballast W. b_1 b_2 b_3 will be three different centres of buoyancy, because in each case we have a simple balance, with the weight of ship b at one end and the ballast W_1 at the other.



We shall, therefore, find m_1 m_2 m_3, or three different metacentres, according as the shifted ballast is placed on a higher or lower platform, and the metacentric heights G m_1 G m_2 G m_3 will be apparently different, although by the common formula it ought to be the same, because the level of the ballast is not taken into account. The greater the height of the ballast the greater will be the heel. The correct position for the ballast would be at X. In the case of small craft such as torpedo boats, destroyers, and single-decked vessels generally, the ballast is always placed far too high up in inclining them, and consequently the G m obtained is apparently less than it really is. In large vessels having several decks it would generally be possible to place the ballast at about the level of the centre of gravity G, and thus obtain correct angles of heel. F. W. C.

March 23rd.

RAILWAY AXLE BEARINGS.

SIR,—I regret that I am unable to answer all the queries addressed to you by your correspondent "Headstock," in your issue of the 13th inst., but I will try to do the best I can in that direction. But permit me here to premise by saying that for many years you have known me as a somewhat persistent advocate, from an economic point of view, if nothing else, for working to obtain the maximum amount of efficiency in all bearings of rolling stock, and hence my special interest. Of necessity the inital step to this end belongs to the brass foundry.

In the selection—if selection I may call it—of a vehicle used in forming a passenger train, I am confined to one, namely, a travelling post-office, this being the only vehicle, so far as I know, that runs a specified mileage day by day. This van runs, out and home again, every day from Aberystwith to Shrewsbury, and so covers 163 miles per day. In October, 1894, I supplied this van with a set of brasses—six—which, when fitted on journals, weighed 62 lb. 11 oz., and when returned to works October, 1895, for general repairs, I found the weight to be 57 lb. 8 oz., the total loss being 5 lb. 3 oz.

Miles run in 362 days, at 163 per day .. .. = 59,606
Total loss for 1000 train miles .. .. = 1·40 oz.
" " " 25,000 " " .. .. = 35·16 "
Total single bearing 25,000 train miles .. .. .. = 5·86 "

The above is no special case of results, but is practically that of three successive sets of brasses. The lubricant is not oil, but just the ordinary yellow grease. In oil the wear would have been considerably less. I trust this information may be of interest to your correspondent "Headstock" and others of your readers.

FOUNDRYMAN.

Oswestry, March 20th.

ROCHESTER BRIDGE.

SIR,—Referring to description of above in your current number, I believe I am right in stating that this very interesting example of cast iron bridges was actually designed by Rowland Mason Ordish for Sir W. Cubitt. I have heard the late Mr. Ordish mention that the wrought iron swing portion was never once used since the date of the opening of the bridge for traffic. In being attributed to another than the actual designer, this bridge shares the fate of most of Mr. Ordish's important works, which, by-the-bye, includes St. Pancras Station roof, the Albert Hall roof, the Holborn Viaduct bridge, &c.—all designed by commission from other engineers, whose names are now incorrectly attached to them. J. W. LEIGH.

17, Barton-street, West Kensington, W., March 24th.

[We publish Mr. Leigh's letter, but we must add that Mr. Ordish's position in these matters was quite well understood by himself, and he was not acting in them as principal any more than many others who receive instructions from the engineer-in-chief of an undertaking.—ED. E.]

W. H. HARRISON FUND APPEAL.

SIR,—After thirty years of scientific writing, Mr. W. H. Harrison's health and strength have completely broken down, and he lies stricken with brain paralysis.

The readers of THE ENGINEER are doubtless familiar with his work. New scientific matter of special interest; lectures delivered at the Royal Institution; reports of meetings of the British Association for the Advancement of Science; descriptions and details of engineering works and plant employed in new industries, were his special forte.

He achieved much success as an experimental photographer. To him is the credit due for the discovery of the gelatine emulsion dry plate and the employment of an alkaline pyro developer. This discovery he gave freely to the public in 1868.

Briefly, during thirty years Mr. Harrison has steadily worked on photographic and kindred scientific matters, but never tried to make pecuniary gain out of his work.

A testimonial fund has been started, and it is hoped that a sufficient sum will be obtained to tide him over his illness and be a solatium in recognition of his services in the cause of scientific progress. It is with much confidence that Mr. Andrew Pringle and myself appeal to all his scientific friends to assist in this most deserving case, and I will gladly receive and acknowledge contributions. FREDERICK H. VARLEY.

82, Newington Green-road, Highbury, London, N.

JABEZ CHURCH.

IT is with great regret that we have to announce the death of Mr. Jabez Church, M.I.C.E., which took place at his residence, 17, Holland Park-gardens, Kensington, on the morning of March 20th, 1896. The cause of death was congestion of the lungs and heart disease.

Mr. Church was born at Chelmsford in 1845, and was educated privately. After finishing his education, he was articled to his father, Mr. Jabez Church, of Great George-street, Westminster, who was also the son of a well-known engineer bearing the same name. Upon the completion of his term of pupilage in 1869, the deceased gentleman was admitted into partnership with his father, and practised as a consulting engineer in conjunction with him until the death of the latter in 1875. He then continued the practice on his own account, and during his too short career, was engineer to, or professionally engaged for, a very large number of gas and water undertakings, far larger perhaps than any of his professional brethren practising in the same branches of engineering.

Mr. Church had a very wide practice in Essex. Amongst other works in that county which he had either designed and constructed, or to which he was consulting engineer, were the Braintree gas works, the Barking gas works, the Brentwood gas works, the Chelmsford gas works, the Enfield gas works, the Epping gas works, the Harwich gas works, the Ilford gas works, the Saffron Walden gas works, the Witham water and drainage works, and the Thetford water works. Besides these he was engaged for the Barnet gas and water works, the Colney Hatch gas works, the Cromer gas works, the Dublin Consumers' Gas Company, the Horley gas works, the Woking gas works, and the Godalming water works. Mr. Church was also the consulting engineer for no fewer than twelve water works, all of which he designed and erected. Chief amongst these are the Henley-on-Thames water works, the Great Marlow water works, the Clacton-on-Sea water works, the Barton-on-Humber water works, the Braintree water works, the Halstead water works, the Goring water works, and the Mid-Sussex water works. He also designed the Gainsborough water works, which are now in course of construction.

Mr. Church was elected an Associate of the Institution of Civil Engineers on May 23rd, 1871, and was transferred to the class of Member on November 27th, 1877, at which time he had already designed and carried out many works of importance, and was engineer to no fewer than fifty corporations and companies. The deceased gentleman was a Past-president of the Society of Engineers, having been elected to that office two years in succession, namely, in 1882-3, his father having enjoyed that distinction ten years previously, namely, in 1872-3. He was also a Fellow of the Geological Society, and a Member of the Meteorological Society.

Mr. Church's practice will be carried on by Mr. Percy Griffith, A.M.I.C.E. and M.I.M.E., who has been professionally associated with the deceased gentleman for the last eight years, and has been in partnership with him since 1892.

TRACTION ENGINES ON ROADS.

A select committee of the House of Commons sat for the first time on Monday, the 23rd inst., in Committee-room No. 13, with a view to taking evidence relating to the laws controlling the use of traction engines on common roads. The Committee was made up of the following members:—Mr. H. Hobhouse, Chairman; Captain Bagot, Mr. Bill, Mr. Griffith-Boscawen, Mr. Vaughan Davies, Mr. Seale-Hayne, Mr. Hermon-Hodge, Sir W. Houldsworth, Colonel Kenyon-Slaney, Sir J. Kinloch, Mr. Luttrell, Mr. Tulley, and Colonel Warde.

The first evidence taken was that of Mr. Rotton, the legal adviser to the Local Government Board, who detailed the laws in existence relating to the subject. The witness cited three Acts of Parliament as controlling broadly the working of traction engines or road locomotives. These are as follows:—The Locomotive Act, 1861, which applies to Great Britain; the Locomotives Act of 1865; and the Highways and Locomotives (Amendment) Act of 1878; the two former being construed together as one Act. The portion of the Act of 1861 referring to the tolls levied upon road locomotives and vehicles drawn by them was considered as being out of the bounds of the inquiry, owing to the practical abolition of tolls on turnpike roads. We may, however, briefly recapitulate the salient points of the sections of these Acts which were given in evidence and still hold good in the regulation of the use of locomotives on roads. In Section 4—1861 Act—it is set forth that it shall not be lawful for any wagon, wain, or cart or other carriage drawn or propelled by locomotive or other engine not having cylindrical wheels to carry any greater weight than is permitted in such vehicles by the General Turnpike Act; and it shall not be lawful for such vehicles having cylindrical wheels to carry over or above the weight of the vehicle any greater weight than 1½ tons for each pair of wheels unless the fellies, tires, or shoes are 4in. or more in breadth; nor to carry a greater weight than two tons for each pair of wheels unless the fellies, tires, or shoes are 6in. or more in breadth. To carry three tons the fellies, tires, or wheels have to be not less than 8in. in breadth. The section further specifies that for every single wheel one-half of that allowed for a pair of wheels must not be exceeded, but in no case must a pair of wheels carry more than four tons, nor one wheel more than one-half of this weight. Should springs be provided on each axle the Act permits an additional sixth of the above-mentioned weights upon each pair of wheels.

Section 5 of the 1861 Act relates to the power of the Secretary of State to prohibit the use of locomotives destructive to highways or dangerous to the public, any person using such locomotive contrary to any order published in the *London Gazette* "shall for every such offence, on summary conviction thereof before two justices, forfeit any sum not exceeding ten pounds." Section 6 sets forth that it shall not be lawful to drive a locomotive over any suspension bridge nor over any bridge on which a conspicuous notice has been placed by the authority of the surveyor or persons liable to the repair of the bridge that the bridge is insufficient to carry weights beyond the ordinary traffic of the district, without previously obtaining the consent of such authority. Should this permission be refused, on the application of either party, the question of insufficiency may be referred to one of her Majesty's principal Secretaries of State, whose certificate of sufficiency gives the owner of the locomotive the right to take the same over the bridge. Section 7 implies that any damage done by locomotives or carriages propelled by the same to turnpike or other roads carried over any stream, watercourse, navigable river, canal, or railway, by means of a bridge, shall be made good by the owner or owners of the locomotive, who shall also compensate any person for obstruction, interruption, or delay, caused by the said damage. Section 9 specifies that no "locomotive, wagon, or carriage," shall be used on the turnpike or other roads "except there be at least two persons to drive or conduct such locomotive. and if more than two such wagons or carriages be attached to such locomotive, one person to take charge of such wagons and carriages." Between the hours of one hour after sunset and one hour before sunrise two efficient lights are to be carried on either side of the front of the locomotive.

The Act of 1865 is described as "An Act for further regulating the use of locomotives on turnpike and other roads for agricultural and other purposes," and repeals the sections 5 and 9 of the 1861 Act." It enacts that every locomotive propelled by steam or any other than animal power on any turnpike road or public highway shall be worked according to the following rules and regulations:—

> "Firstly, at least three persons shall be employed to drive or conduct such locomotive, and if more than two wagons or carriages be attached thereto, an additional person shall be employed, who shall take charge of such wagons or carriages.
>
> "Secondly, one of such persons, while any locomotive is in motion, shall precede such locomotive on foot by not less than sixty yards, and shall carry a red flag constantly displayed, and shall warn the riders and drivers of horses of the approach of such locomotives, and shall signal the driver thereof when it shall be necessary to stop, and shall assist horses, and carriages drawn by horses, passing the same.
>
> "Thirdly, the drivers of such locomotives shall give as much space as possible for the passing of other traffic.
>
> "Fourthly, the whistle of such locomotive shall not be sounded for any purpose whatever; nor shall the cylinder taps be opened within sight of any person riding, driving, leading, or in charge of a horse upon the road; nor shall the steam be allowed to attain a pressure such as to exceed the limit fixed by the safety valve, so that no steam shall blow off when the locomotive is upon the road.
>
> "Fifthly, every such locomotive shall be instantly stopped, on the person preceding the same, or any other person with a horse, or carriage drawn by a horse, putting up his hand as a signal to require such locomotive to be stopped.
>
> "Sixthly, any person in charge of any such locomotive shall provide two efficient lights to be affixed conspicuously, one at each side on the front of the same, between the hours of one hour after sunset and one hour before sunrise."

The second of the just-mentioned regulations was afterwards repealed, as will be hereafter mentioned, while the sixth is practically embraced in Section 9 of the 1861 Act. The penalty for the non-compliance with any of the above regulations is not to exceed £10.

The fourth section fixes the maximum limit of speed of locomotives at four miles per hour along any turnpike road or public highway, and at two miles an hour "through any city, town, or village," any person acting contrary to these instructions shall be liable to the forfeiture of a sum not exceeding £10. Two important sections of the Act relating to the size and weight of locomotives, and the power of local authorities to make orders as to hours, &c., during which locomotives may pass through cities, &c., have been repealed by the 1878 Act, particulars of which we are now about to give.

The Highways and Locomotives (Amendment) Act, 1878, is divided into three parts, and does not apply to Scotland and Ireland. Part I. refers to highway law, and contains one section—23—of particular interest to owners of traction engines. This section—devoted to "extraordinary traffic" enacts that:—

> "Where by a certificate of their surveyor it appears to the authority which is liable or has undertaken to repair any highway, whether a main road or not, that, having regard to the average expense of repairing highways in the neighbourhood, extraordinary expenses have been incurred by such authority in repairing such highway by reason of the damage caused by excessive weight passing along the same, or extraordinary traffic thereon, such authority may recover in a summary manner from any person by whose order such weight or traffic has been conducted the amount of such expenses as may be proved to the satisfaction of the court having cognisance of the case to have been incurred by such authority by reason of the damage arising from such weight or traffic as aforesaid."

In connection with this section it should be pointed out that the term "excessive weight" is extremely vague, and, although pressed for its definition, Mr. Rotton, in his evidence, declined to give a legal decision, but thought that no owner of a locomotive used on a road under ordinary conditions would be liable for employing excessive weight. It will, of course, be apparent that "extraordinary traffic" may be attributed to other means of locomotion than traction engines. Mr. Rotton cited several cases of litigation involving these terms, and considered the decisions arrived at as being far from unanimous.

Part II. of the 1878 Act is devoted to the Amendment of the Locomotive Acts of 1861 and 1865, of which Section 3 of 1861, and Section 5 of 1865, are repealed so far as relates to England. According to this amendment it shall not be lawful to use on any turnpike road or highway a locomotive constructed otherwise than in accordance with the following provisions:—

> "1. A locomotive not drawing any carriage, and not exceeding in weight three tons, shall have the tires of the wheels thereof not less than 3in. in width, with an additional inch for every ton or fraction of a ton above the first three tons; and
>
> "2. A locomotive drawing any wagon or carriage shall have the tires of the driving wheels thereof not less than 2in. in width for every ton in weight of the locomotive, unless the diameter of such wheels shall exceed 5ft., when the width of the tires may be reduced in the same proportion as the diameter of the wheels is increased, but in such case the width of such tires shall not be less than 14in.; and
>
> "3. A locomotive shall not exceed 9ft. in width or fourteen tons in weight, except as hereinafter provided; and
>
> "4. The driving wheels of a locomotive shall be cylindrical and smooth soled, or shod with diagonal cross-bars of not less than 3in. in width nor more than ¾in. in thickness, extending the full breadth of the tire, and the space intervening between each such cross-bar shall not exceed 3in."

The paragraph commencing "secondly" of Section 3 of the 1865 Act, above alluded to, is repealed by this Act, and now reads as follows:—"Secondly, one of such persons, while the locomotive is in motion, shall precede by at least 20 yards the locomotive on foot, and shall, in case of need, assist horses, and carriages drawn by horses, passing the same." Section 30 of the 1878 Act provides that all steam locomotives shall be constructed to consume their own smoke under a penalty not exceeding £5 for every day during which such locomotive is used on any road. Section 31 defines the authorities which have power to make bye-laws as to the hours during which locomotives are not to pass over the turnpike roads or highways, the hours being in all cases consecutive, and no more than eight out of the twenty-four, and for regulating the use of locomotives upon any highway or preventing such use upon any and every bridge where it would be attended with danger to the public, a fine, not exceeding £5, being the penalty upon any person acting contrary to such bye-laws. Section 32 of the 1878 Act enacts that—

> "A county authority may from time to time make, alter, and repeal byelaws for granting annual licences to locomotives used within their county, and the fee—not exceeding ten pounds—to be paid in respect of each licence; and the owner of any locomotive for which a licence is required under any byelaw so made who uses or permits the same to be used in contravention of any such byelaw shall be liable to a fine not exceeding forty shillings for every day on which the same is so used, all fees received under this section being carried to and applied as part of the county rate.

Upon the conclusion of the evidence of Mr. Rotton, the chairman of the committee called upon Mr. Chittenden, the chairman of the Traction Engine Owners' Association, a society of one hundred members, including owners and users of road locomotives, to give evidence. This gentleman stated that there were at present in use in England and Wales about 8000 of these engines, 700 of which were employed in Kent alone. As representative of the above-mentioned association, Mr. Chittenden complained that traction engine owners should have to take out a licence for each county; that, with the exception of Kent and Sussex, the authorities of which granted rebates of 50 per cent. on all licences taken out in adjoining counties, other county authorities insisted upon the maximum fee of £10. In the opinion of the witness one fee should suffice for the whole of England. He also suggested that a greater uniformity in the bye-laws of neighbouring counties should exist respecting the close hours—if such hours were necessary—and that the reduction of the restricted hours should only take place in towns having a population of 10,000 and upwards, the said hours being those when the street traffic was heaviest. With regard to the maximum limits of speed, Mr. Chittenden recommends that these should be raised to five or six miles an hour in country districts and three miles in larger towns. Besides advocating the raising of the limit of maximum weight of traction engines from 14 tons to 20 tons and the exemption of steam rollers from licences, the witness considers that the present law, confining the wheels of road locomotives to one pattern, might advantageously be altered to allow local authorities to sanction the use of other approved forms. Speaking generally, Mr. Chittenden desires to see the road locomotive put on the same footing as ordinary road vehicles.

Upon the conclusion of Mr. Chittenden's evidence, the Committee adjourned until yesterday (Thursday).

THE MERSEY ESTUARY.

The report of the acting conservator of the Mersey, Sir G. H. Richards, K.C.B., F.R.S., for 1895 has been published fully a month earlier than last year, and very much earlier than has been the case in former years. This is a decided improvement, and as the effect of the Manchester Ship Canal upon the *regime* of the estuary will be raised before the Committees of both Houses of Parliament during the current session, Admiral Richards' report will be heard of frequently.

The annual reports are more than usually interesting owing to the dredging operations on the bar, and also to the completion of the Manchester Ship Canal, which in some ways modifies the conditions of the estuary to a greater or less extent.

On the bar the work of dredging has been continued. The new 3000-ton sand pump dredger G. B. Crow, similar to the Brancker, was delivered last autumn, and commenced work at the Queen's Channel towards the end of November, from which it removed upwards of 220,000 tons. The Brancker was employed on the bar during a portion of each month o the year, and worked there in all 3127 hours; during this time 2,570,700 tons were removed.

The smaller dredgers have been taken from the neighbourhood of the bar since the first month of the year. The total amount of material removed from the bar is stated to be 2,606,000 tons. In addition to this, the Brancker has removed nearly 2,000,000 tons from the easterly side of Taylor's bank, which lies to the north and west of the Queen's Channel.

The material consists of sand with a large proportion o silt, and the pumps not being so efficient as formerly, when there was less admixture of silt, the Dock Board decided to fit a tender with new apparatus, consisting of pumps and an arrangement of pipes to be lowered to the bed of the channel. By forcing jets of water through these pipes at high pressure the silt is disturbed and carried by the ebb tide into deep water. The average time of working each tide is about four hours, and although it is difficult to estimate the amount of material removed by this means, there is no doubt that the general effect is good. The result of the dredging operations during 1895 is regarded by the conservator as very satisfactory. The minimum depth on the bar at dead low water of spring tides is 22ft., and this occurs only in a few spots on the outside line of the area operated upon. The maximum depth is 29ft., the mean 25ft. In mid-channel and for a width of 500ft. a depth of 24ft. can be carried at low water of spring tides. Since the commencement of operations in September, 1890, 11,742,000 tons have been dredged at the bar, and the plant now in the possession of the Mersey Dock Board appears adequate to maintain and still further improve the navigation.

In addition to the dredging at the mouth of the estuary, 146,000 tons have been removed by the Brancker and 772,000 tons by other dredgers in the neighbourhood of the landing stage, at which Atlantic steamers now arrive and depart, to the great convenience of the passengers. When the work was commenced the depth opposite the stage was in places only 8ft. at low water spring tides; now there is nowhere less than 26ft., and it is intended to persevere until a depth of at least 30ft. is obtained. During the last half of 1895, 172 transatlantic and other large steamers have used the stage. The London and North-Western Railway now run trains through from Euston to the landing stage without stopping in three and a-half hours, and passengers can proceed at once on board ship.

The gales during 1895 were neither so numerous or so intense as in 1894; until December there was an extraordinary absence of very high velocities, but that month was a stormy one. Throughout the year, as in the previous year, the gales were nearly all from the west, two only coming from the south-west, and one from the north-west.

The report shows in an appendix the increased difficulty which is found in the disposal of refuse. Not only are dredgings to the extent of 2,500,000 tons sent to sea, but we find upwards of 700,000 tons of heavy material got rid of in this manner. The dredgings from the estate of the Mersey Dock and Harbour Board amount to upwards of 1,500,000 tons from the Manchester Ship Canal—including the Bridgwater Canal—570,000 tons, Garston Docks contribute 100,000 tons, while the city of Liverpool sent 150,000 tons, and Salford, which lies sixty or seventy miles away from the place of deposit, sent 42,000 tons last year.

Under the head of "Manchester Ship Canal," we observe that dredging operations have been carried on for deepening the approach to the canal entrance at Eastham, but the result of this work is not recorded. It appears also that timber dolphins have been constructed on either side of the channel below Eastham for the convenience of vessels entering the canal. The report also refers to the condition of the Mersey between Runcorn and Warrington, which was especially noticed in the report for 1894, and states that there has been a still further drop in the height of high water at Warrington to the extent of 1ft. 7in., which added to 1ft. 1in. previously noted, shows a deficiency of 2ft. 8in. This is a very remarkable change, and must call for the serious attention of all authorities interested in the navigation of the river; no doubt the question will be threshed out by the Committees on the Ship Canal Bill, and if it is proved that the works of the Ship Canal have caused the deterioration of the estuary, the Canal Company will, it may be supposed, be called upon to make some alterations. It is stated by some engineers that the only real cause of any such damage would probably be undue abstraction of fresh water from the old bed of the river at Warrington, a great portion of which has been allowed to pass into the lower reaches of the Ship Canal through the sluices at Latchford. The report states that a weir on the old river has been removed, that a cutting has been widened, and other works have been done which will allow from 18,000,000 to 20,000,000 cubic yards of water to flow through and along the old river course past Warrington in twenty-four hours; whereas, until recently, since November, 1893, less than one half of this quantity flowed along the course. The channel is still insufficient for dealing with big floods from the uplands. These works are a step in the right direction, but may be found insufficient if the figures quoted above are correct. It is, however, possible to increase the scouring power, as we pointed out last year, by impounding high tides, and allowing the water to escape by means of sluices at the upper end of the estuary.

The Bill promoted by the Ship Canal Company seeks power to close the tidal openings. Nothing is said about raising the normal level of water in the Ship Canal, which now stands at 14ft. 2in. above Old Dock sill at Liverpool, but if the Bill passes in the present form it will enable the Canal Company to do this. We do not know whether they have power to construct large sluices at Walton. If that were done, our recommendations, which now appear to be partially, would then be completely adopted, and we have no doubt that the result to the estuary would be most beneficial.

The traffic in and out of Liverpool was greater than ever, 44,856 vessels passed in and out, a daily average of 123 vessels. There were 1928 more than the previous year, and the Custom House tonnage returns are:—Inwards, 9,061,648 tons; outwards, 9,406,180 tons, a total of 18,467,808 tons, an increase, as compared with 1894, of no less than 752,945 tons.

The Cardiff Exhibition of 1896 promises to be one of the largest, if not the largest, ever held in Wales. All important features of its industries are to be well represented.

OWARD AND TAITE'S RAILWAY CARRIAGE WARMING APPARATUS.

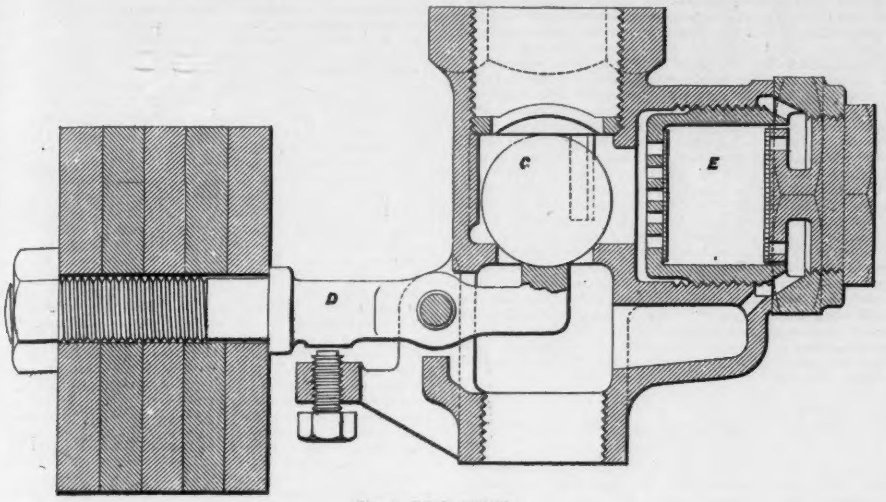


Fig. 1—DRIP VALVE

POSSIBLY the greatest difficulty which engineers have to combat to secure the effective working of railway carriage warming apparatus in which steam is employed as the heat-giving medium, is the accumulation of condensation water in, and the consequent freezing up of the pipes. With the object of obviating this and other defects, Messrs. Taite and Carlton, of Queen Victoria-street, E.C., are introducing a system which in some important details differs from others in use at present. In this apparatus live steam from the locomotive boiler, reduced to a suitable pressure by means of a sensitive reducing valve, is employed. At the reduced pressure of, say, 40 lb., it is conducted throughout the whole length of the train by means of a continuous train pipe, the connection between the vehicles being made by flexible hose and couplings in the usual manner, with the exception that the engine and tender are coupled up by means of flexible metallic couplings having ball-and-socket joints. From the main pipe underneath each coach the steam passes through branch pipes laid in transverse heating chambers in the floor of each compartment, the said branch pipes being connected at their other ends to a drain pipe placed in a lower plane than, but running parallel with, the main supply pipe. Both the supply and the drain pipes are given a certain amount of fall at about the middle of their lengths, and are fitted at their lowest points with drip valves, so that the water of condensation may find a continual outlet from the system without the escape of steam, which would be objectionable to passengers. The hose couplings have also provided in them valves for the same purpose. In the floor of the compartment, and above the heating chambers, which are open to the atmosphere below, gratings are placed. These may be opened or closed at the will of the passengers concerned by operating with the foot a hit-and-miss arrangement, so that the incoming supply of warmed air may be regulated without necessitating the adjustment of any valve. It is claimed by the makers that by bringing in the warm air through the floor in this manner the warmth is distributed more evenly than in other systems, and that the feet of the passengers, where the cold is most acutely felt, derive a corresponding benefit.

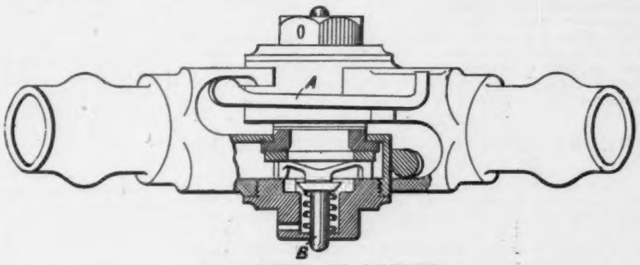

Fig. 2—DETAIL OF COUPLING

The hose pipe couplings between the coaches are very similar in construction to those employed with the Westinghouse brake, but are so designed that they cannot inadvertently be coupled up with the latter. Fig. 2 shows a pair of these couplings in plan, the drip valve for getting rid of the condensation water being shown in section. It will be seen that, instead of the engaging parts A being rigid, as in the case of the brake coupling, they are made of spring steel, and encircle the end of the coupling. This arrangement is rendered necessary owing to the steam-tight joint being made by non-elastic material. The drip valve in the coupling will be readily understood from the illustration. It consists of a conically seated disc with a projecting stem round which is coiled a helical spring, so that when steam pressure is in the pipes the valve is closed against the resistance of the spring, but when the pressure is released the valve opens automatically, and allows the escape of water. It will be noticed that the stem of the valve projects slightly through the coupling. This arrangement enables the removal of any particles of dust or corrosion, which may accumulate on the seating, to be removed by tapping the end of the stem. In order to prevent scalding by the escape of steam when uncoupling vehicles without shutting off the supply of steam to the apparatus throughout the train, cocks having by-passages are affixed on the pipe at the end of each coach. These are normally open to allow of a flow of steam through the apparatus, but when closed the by-pass is opened, enabling the steam accumulated in the hose pipes only to escape.

The principal drip valves, of which a sectional illustration is given in Fig. 1, are applicable to any system in which one line of main steam pipes is employed. The valve consists of a metal ball C—held off its seat by a weighted arm D, when the steam is shut off and the principal condensation is going on—but which the pressure of steam closes automatically. Any leakage which takes place while the apparatus is under steam must be through the device E, consisting of a metal cylinder screwed into the body of the valve and filled with asbestos fibre, which is compressed to the desired extent by means of a nut, and through which the water percolates, finally escaping through the passage shown. It should be stated that an essential feature in this system of steam heating is the provision of a small pet cock at the extreme rear of the train, whereby a jet of steam is continually allowed to escape, thereby ensuring its circulation through the pipes.

The system, we are informed, as a whole, has not so far been adopted in this country, but the drip valves have been applied with satisfaction to other systems at work. The apparatus—so far as can be judged from the inspection of a full-size model under steam—appears to possess the necessary qualifications for successful working.

THE NEW DESTROYERS FOR THE ARGENTINE NAVY.

IN our issue of March 13th, in the column of "Miscellanea," we noted as under construction by Messrs. Yarrow and Co., of Poplar, for the Argentine Government, a number—four—of torpedo boat destroyers of what has come to be known as the Sokol type, which our readers will remember as the name of a vessel of the destroyer class built by Messrs. Yarrow for the Imperial Russian Government.

Although the vessels now in hand at Messrs. Yarrow's shipyard for the Argentine Navy are of the same general type as the Sokol, they differ from her so much in many of her essential features that a somewhat detailed description is necessary to enable those interested in such vessels to form a proper conception of them.

The dimensions of the new destroyers are:—Length over all, 190ft.—the same as the Sokol—and breadth, 19ft. 6in., or 1ft. more than that vessel. The shape of the hull above the water-line is considerably modified, there being no "tumbling home" of the sides, and consequently the deck is the full width of the vessel and very roomy. An important alteration has been made—by special desire of the Argentine Naval Commission—in the shape of the fore parts of these boats. This consists in giving the bows a considerable flare, so as to throw off the seas when going against them, and keeping the decks drier. It is also of importance when firing the 14-pounder gun on the conning tower forward, as spray interferes with taking a correct aim.

The leading feature in the construction of the hull in these vessels is that both the sides and deck for the entire length of the machinery and boiler space are armoured. The first vessel of the "destroyer" type armoured in this manner was built by Messrs. Yarrow for the Japanese Government some seven years ago, and during the late war between Japan and China, this protection was found by experience to be of the greatest value. This vessel—named the Kotaka—led two important torpedo attacks during the recent war, and came out of them comparatively uninjured, while other similar boats which were not armoured in the same way, were in many instances completely destroyed.

Of necessity the armour adds considerably to the weight of the vessel, and reduces its speed, when the same propulsive power is employed as without it; but the Argentine authorities are of opinion that it is worth sacrificing something in speed for the sake of protection. There is, however, other gain accruing from the use of armour, for it not only protects the machinery and vessel, but gives greater confidence and energy to the engine-room staff, owing to the protection afforded them by it. In a head seaway its extra weight is certainly rather an advantage than otherwise. In addition to the protection afforded by the armour-plating, the boilers of the vessel are entirely surrounded by coal bunkers, which are unusually capacious, as they will hold about 80 tons of coal.

The subdivision of the hull by water-tight bulkheads in the new vessel is very complete, and there is a total absence of those dangerous ingenuities—especially in small vessels—called water-tight doors, which are a delusion and a snare.

The whole of the fore part of the hull, under deck in the new vessels, is devoted to the accommodation of the crew, the executive and warrant officers being comfortably berthed abaft the engine-room. Here we must draw attention to the fact that in these vessels the commanding officer's cabin, as well as the officers' mess-room, is next to the engine-room, where the motion of the vessel is least felt. In British torpedo-boat destroyers, the commanding officer is accommodated quite aft in the vessel, where sound sleep when off duty is well-nigh impossible, and where he is most out of the way of those who may have to consult him. It is also noticeable that the galley and kitchen in the Argentine boats are in close proximity to the pantry, a point of some importance for the comfort of officers in bad weather.

The propelling machinery of the new vessels consists of two sets of inverted cylinder triple-expansion engines of Messrs. Yarrow's usual construction, but many of their details have been modified in directions shown to be desirable by the most recent experience. The balancing of machinery has been made the subject of very careful and extensive study by the builders of these vessels, as the question of vibration has become a matter of first consideration in lightly built vessels which have high-speed propelling engines.

The boilers of the new destroyers are six in number, of the Yarrow water-tube type, and capable of easily supplying sufficient steam for about 4000 indicated horse-power. Forced draught is provided for by two fans, which are placed horizontally, and rotated by small engines which are laid upon the floor of the stokeholds.

The armament of the vessels comprises:—One 18in. torpedo tube built into the stem for bow-fire; two 18in. swivel torpedo tubes aft for discharge on either side; one 14-pounder quick-firing gun on the conning tower forward; three 6-pounder quick-firing guns on deck aft, and two Maxim automatic machine guns, one on either side just above the conning tower.

The vessels have the usual steam steering gear, electric light machinery, distilling apparatus, &c. &c. Their guaranteed speed, carrying a load of 35 tons, is 26 knots, but when the extra weight of armour and fuller model is considered, this is undoubtedly a fine result.

THE U.S. RAM KATAHDIN.

THE Katahdin is the latest addition to the United States Navy, and although as regards speed she has failed to come up to the contract requirements, yet her efficiency as a ram is but slightly impaired. She needs no heavy armanent, for she is her own weapon. Her destructive power is indicated by the following figures:—At an ordinary cruising draught of 15ft. and steaming at 16 knots speed she will strike a blow of over 24,700 foot-tons, a force capable of sinking any vessel that now floats. At 15 knots speed the blow would be about 21,700 foot-tons, and at 10 knots 9660 foot-tons.

The Katahdin's greatest *forte* lies in her strength as a body and the excellence of her model for manœuvring and offensive and defensive powers. The stem or ram proper is formed by a 14-ton casting, and massive girders and longitudinals converge to it from deck, keel, and sides, well stiffened by breasthooks and intercostal frames and beams, so as to make all parts of the ship take the effect of the blow and ensure no local weakness. The keel of the vessel is elliptical, and it is remarkable to see how rapidly she can turn and how quickly she answers her rudder, and this feature is absolutely necessary in a vessel intended for efficient harbour service. The bow and stern lines are remarkably full and hard, and there is no deadwood or cutwater whatever. A sharp knuckle formed where the side and deck armour meet, about 8in. under water, runs from the centre of the stem the whole length of the ship, and this will tend to rip out the side of a vessel struck. There are no important projections above deck with the exception of the conning tower, which weighs 45 tons and is 18in. thick, and the smoke pipe and ventilators, which at the base have 6in. inclined armour for about 3ft. high. The deck is convex and completely armoured, and there are two strakes of side armour below water from 3in. to 6in. thick. Four 6-pound rapid-fire guns are carried, two forward and two aft, in small barbettes as a protection against light torpedo craft.

The dimensions of the vessel are well known, but it may be well to state here that she is 251ft. long over all, 43ft. 5in. extreme beam, and 15ft. mean draught; displacement 2183 tons. The engines are twin-screw horizontal triple expansion, with cylinders 25in., 36in., and 56in. diameter by 36in. stroke, designed for 4800 horse-power at 150 revolutions. There are two double-ended and one single-ended Scotch boilers, with 12,160 square feet of heating surface and 354 square feet of grate surface.

On December 10th, 1894, the Katahdin made her first preliminary trial trip over a measured mile course off Southport, Me. The propellers had a diameter of 10ft. 6in., 15ft. 2in. pitch, and 30 square feet blade area. Her bottom was somewhat foul, and the engines not working satisfactorily, a speed of but 14·4 knots was attained with 2440 indicated horse-power, the slip being 27·4 per cent. The vessel was then taken to the Charleston navy yard and docked. New wheels of 10ft. 10in. diameter, 14ft. 4in. pitch, and 38·5 square feet blade area were fitted, and late in March, 1895, the second speed trial was made. A speed of 15·71 knots was attained, with 4124 indicated horse-power, and the slip was reduced to about 22 per cent. During April and May similar full power trials were made, the maximum speed obtained being 16·06 knots, with 5749 indicated horse-power and 27 per cent. slip, the power on this run being no less than 20 per cent. in excess of contract requirement, and yet the speed was one knot less. On May 31st a progressive trial from 8 knots upwards was decided upon, but after reaching a speed of 13 knots the bed plate of the after or starboard engine broke, and the vessel returned to Bath under one engine. It was not until August 17th that the progressive trial could be concluded, the maximum indicated horse-power developed being 5059, which gave a speed of 15·86 knots and 25 per cent. slip. In the meantime a large cofferdam 40ft. long and 50ft. wide had been built by the Bath Ironworks, and when the Katahdin had completed her progressive trials with wheels No. 2, the stern was placed in the cofferdam, and wheels of 12ft. diameter, 14ft. pitch, and 36 square feet blade area were fitted. On August 31st a progressive trial was made with these wheels, and they showed considerable improvement over their predecessors. These screws had an inclined element aft of 15in. in 56in., and were designed by the United States Bureau of Steam Engineering, from data received from the previous trials. The maximum speed was 16·07 knots, with 4900 indicated horse-power and a slip of but 16·7 per cent. The Bath Ironworks, having worked out all the vessel's performances on a theoretical basis, then submitted them to the Navy Department, and the latter officials decided that all that could be done had already been done, and that the only course left was to run the vessel on her official trial, and get all they could out of her.

This the builders decided to do, as they had already spent 40,000 dols. in experimenting with her. She was accordingly taken to the Charleston navy yard and again docked. It was then discovered that one of the wheels had sprung somewhat, and the tips of the blades had been bent very badly by striking against the side of the ship. New wheels were therefore hurriedly cast, similar to the previous ones, but only 11ft. 10in. diameter, and, after having these fitted, she left Boston, and steamed to Long Island Sound for her official speed trial. This trial took place in very unfavourable weather on October 31st, the result being that but 16·11 knots mean speed was attained with about 5300 indicated horse-power, or over 10 per cent. more than the contract specified.

It is undoubtedly the model of the Katahdin that is faulty, but Mr. William A. Fairburn of the Bath Ironworks, who has made all the calculations and curves of the vessel's performances during her speed tests, is confident that the speed could be increased from one-half to three-fourths of a knot per hour by moving the propellers much farther astern. A couple of struts and a new length of shafting would be necessary, but the total cost of the change would not exceed 5000 dols. The fact of having the propellers so far astern would certainly prove a slight detriment to the efficiency of the ship for harbour service, but this could be overcome to a great extent by building propeller guards that would project so far from the sides of the vessel as to completely protect the wheels. This is done on most torpedo craft, and it should be remembered that the propellers as now located on the Katahdin project beyond the side of the ship and are unprotected. It is said that chief engineer Melville of the Bureau of Steam Engineering has proposed to the Secretary of the Navy that the wheels be moved aft, and if this proposition is approved it will be interesting to watch the result of this trial.

The Katahdin has made over fifty runs over the measured mile during her preliminary speed trials. For low speed up to about 13 knots the model is admirably adapted, and at 13 knots the Admiralty displacement coefficient of performance is 260. This good performance at low and medium speed is undoubtedly due to the small wetted surface of the vessel. At 15 knots the performance coefficient has dropped to 165, and at 16 knots it is but 135. All the propellers fitted have brought out about the same final results, and as slip was decreased so were revolutions and to a certain extent indicated horse-power, and as regards the prime object—speed—the first wheels fitted were almost as satisfactory as the last ones. It is also a well-known fact that the change in the wheels made just before the vessel went out on her official trial was not by any means beneficial to her.—*Marine Review.*

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Steel arch bridge.—Work is now in progress on the foundations for the great steel arch bridge over the Niagara River gorge, just below Niagara Falls, which is to replace the present suspension bridge on the same site. This is the bridge nearest to the Falls, below it being the cantilever bridge of the Michigan Central Railroad and the double-deck suspension bridge for the Grand Trunk Railway and a roadway. The new bridge will have two arched trusses of 840ft. span, with a rise of 150ft., the trusses being 26ft. deep and spaced 30ft. apart at the centre and 68½ft. apart at the abutments. The crown of the arch will be about 170ft. above the water. Deck truss spans of about 200ft. will extend from the bridge proper to the cliffs. The floor will be 46ft. wide. In the middle will be a space 22ft. 9in. wide for a double-track electric railway; on each side will be an 8ft roadway; and outside these again will be sidewalks 3ft. 9in. wide. Work will be carried out from each end, the unfinished portions being sustained by anchorages, as the use of false works is impossible. The present bridge will be kept open for traffic during the construction and until the completion of the new bridge. About 4,000,000 tons of steel will be required. On the New York side the foundations are carried down to solid sandstone rock, but on the Canadian side they rest upon a compact mass of gravel and boulders, and are carried back to the solid vertical rock of the cliffs to receive the horizontal thrust. The foundations consist of four masses of concrete, one for each end of each arch, with a facing of limestone masonry, the pressures being 220 lb. per square inch on the masonry and 101 lb. per square inch on the concrete, or 35 lb. vertical pressure per square inch on the base of the foundation. The largest metal arch bridges now in existence are as follows:—

	Feet span.	Feet rise.
Luis Bridge, Oporto, Portugal	566	146
Gonalit Bridge, France	542	170
Pia Maria Bridge, Portugal	525	121
Eads Bridge, St. Louis, U.S.A.	520	47
Washington Bridge, New York, U.S.A.	510	91¾
Paderno, Italy	492	123
Park Bridge, Rochester, U.S.A.	428	67

Railway water supply.—Owing to the injurious effects of the water supplied to its locomotives, necessitating renewing all the tubes of 200 locomotives every year, the Long Island Railroad has now established a central source of water supply, and pumps the water through a pipe line to its principal terminal, a distance of ten miles. The supply is taken from several wells 24in. diameter, and 38ft. deep, driven into a water-bearing formation which yields a very pure soft water. The wells are lined with perforated vitrified clay pipe, and in each well is a 4in. suction pipe; the upper end is connected to a horizontal suction main, extending to the 16in. suction main at the pumping station. The pumping plant consists of two Worthington horizontal triple-expansion engines, with a total capacity of 4,000,000 gallons per twenty-four hours, and return tubular boilers carrying 125 lb. steam pressure. From the pumping station the supply main is laid along the railway, and consists of 8½ miles of 12in., and one mile of 10in. pipe, all cast iron, except that 10in. wrought iron pipes and bends are used for a submarine crossing of Dutch Kills Creek. Shut-off gate valves are placed at intervals of ¾ mile to admit of inspection and repair. This main supplies a stand-pipe or water tower, 20ft. diameter, and 90ft. high, four railway stations, about ten signal cabins, and the terminal station, freight yards, shops, engine tanks, &c., as well as the boilers of the large ferry boats carrying passengers and wagons across the East River from Long Island City to New York. The engine tenders take water from tanks or water columns in the yards, and not direct from the main. Fire hydrants of 4in., 6in., 8in., and 12in. diameter, are placed at short intervals, and gate-valves and air cocks are also provided. Water is supplied for some large manufacturing plants.

The Nicaragua Canal report.—The board of engineers appointed by the United States Government to report on the feasibility and cost of constructing the proposed Nicaragua Ship Canal has made its report, and estimates the cost at £26,000,000. The most serious problems affecting the design and construction of the canal at the present time are those involved in the heavy rainfall and consequent discharges from the lake and streams, whose variations of surface and volume must be taken into account. The rainfall record at Greytown for a period of three years shows a mean of 267in. A record at Rivas, on the west side, for fourteen years gives a mean of 65in. In addition to these there is reliable information of precipitations of 3in. in an hour, of 9in. in nine hours, and 35in. in eight days. A record of nearly 25ft. of water in a year on the Caribbean coast diminished to 5½ft. between the Lake Nicaragua and the Pacific, needs no comment to indicate the important results that must ensue with reference to matters of local drainage and engineering construction. As to the climate of Nicaragua, it is the continued moderate temperature, in conjunction with the high humidity, that so seriously reduces the value of physical labour in the tropics. There has never been any yellow fever at Greytown, except when imported. The heavy rainfall will increase largely the cost of excavating the deep mud at several embankment sites, in excavations, building embankments, &c. The natives are not likely to prove useful in the severe and steady work of canal construction. Jamaican negroes, such as have been employed on the Panama Railway, are docile, and, from a tropical point of view, industrious and fairly effective. They will undoubtedly form the labour supply for the canal. Wages are only about half as much as in the United States, but the efficiency of the labourers is proportionately much less. As a matter of fact, the Jamaica negro is constitutionally opposed to hard work, wherein lies one reason of his health and longevity. Machinery will be used largely, but will be of little value after the completion of the canal, and little, if any, will be worth removal. Its entire cost would, therefore, be charged to the canal construction, making the plant charge higher than usual. There are now no shops or facilities of any kind on or near the canal line, and they will have to be supplied as adjuncts of the work. Skilled labour will have to be imported. Fuel will cost more than double its cost in the United States. Freight on materials and supplies will increase their cost greatly, particularly if sent to interior points. The entrance to the Atlantic harbour at Greytown, as proposed by the company, is too near the angle of the coast line, and the entrance to the canal should be moved eastward about a mile and a-half. The harbour throughout should be dredged to 30ft. below water, and its depth increased to six fathoms. The Ochoa dam, as proposed by the company, is to be a rock-fill across a powerful river, on a sand foundation. A dam so constructed, the Commission says, has no precedent, and its erection in conflict with the unknown volume of the floods presents grave difficulties. In regard to the western division, from the lake to Brito—the Pacific entrance—the information with reference to the site proposed for the La Flor dam indicates that its construction is impracticable, and the Commission suggests an alternative low-level route, which offers no special difficulties in construction. As to the terminus at Brito, the Commission suggests the desirability of moving it southward from the location proposed by the company. The report, closes with the following general conclusion:—"The official estimate by the company of £13,000,000 is insufficient for the work. In several important cases the quantities must be greatly increased, and in numerous cases the unit prices do not make proper allowance for the difference in cost of work between the United States and Nicaragua. The provisional estimate by the Board is £26,000,000. It should be understood that the existing data are inadequate as a basis for estimating the cost of many of the structures; some portions of the work may cost more, others less, but in the judgment of the Board the entire project can be executed for about the total amount of its estimate. For obtaining the necessary data for the formation of a canal project, eighteen months' time, covering two dry seasons, and an expenditure of 350,000 dols., will be required." The Panama Canal suffered from the total absence of preliminary study and investigation, but the Nicaragua Canal is in no sort of danger of this kind, as the most careful and complete surveys, borings, investigations of conditions, &c., have been made.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, March 16th.

THE New York bankers are trying their best to prevent the beginning of another gold outflow to Europe until after the Presidential nominations. They know a large gold exportation will arouse the people against monometallism. The iron trade has been dull for a week, but active buying may set in at any time. Prices have receded slightly. Pig iron production has also fallen a fraction, and the report is a few more furnaces will blow out this month. Steel makers who usually secure large contracts in March for summer delivery have not yet entered the usual amount of business. Rail manufacturers have not booked half the contemplated business for February and March, but they anticipate compensating activity in April, particularly in girders for electric lines. Billets have weakened close to cost, and large consumers refused this week to place orders. Lake ore miners cannot quite satisfy buyers at large that they can prevent a break in prices. Structural steel makers have run across a large amount of probable business. Bridge iron makers are not very busy, but all railroad companies contemplate more or less bridge building during summer and autumn. Manufacturers then anticipate a busy time. There is less disposition to look far ahead, the excuse being that with such enormous open-hearth capacity, as well as Bessemer capacity, there is no need of taking a thought for the morrow. A further decline in pig iron production is probable, as stocks have increased 250,000 tons in four months.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

GOOD attendance on 'Change. The demand for steam coal remains very moderate, and the shipments for the past week were under the average. House coal shipments are affected by the warmer weather, but prices remain without change. Tin-plates show no improvement in demand, and prices are weaker. The iron and steel works are well employed.

Coal: Best steam, 8s. 3d. to 8s 6d.; seconds, 8s.; house coal, best, 10s. to 10s. 3d.; dock screenings, 5s.; colliery small, 4s. 3d. to 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s. 11d.; hematite warrants, 48s. 5d., f.o.b., Cumberland; Middlesbrough, No. 3, 38s. 5d. prompt; Middlesbrough hematite, 45s. 10½d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 15s.; light ditto, £5 to £5 5s. f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 2s. 6d., all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s.; Siemens, coke finish, 9s. 3d.; ternes, per double box, 28 by 20 C, 21s. to 22s. Pitwood: 15s. 3d. to 15s. 6d. London Exchange telegram: Copper £4 15s. 7d.; Straits tin, £60 5s. Freights: Outwards, steady; homewards, firmer.

LAUNCH.—Messrs. Fleming and Ferguson, shipbuilders, &c., Paisley, launched, on the 17th inst., the steel screw steamer Sir Evelyn Wood, built to the order of the British Government. The dimensions of the vessel are 160ft. by 24ft. by 14ft. moulded. The Sir Evelyn Wood is intended for the transport of heavy ordnance, and to meet the requirements of this work has been built with specially heavy scantlings. Machinery for the vessel will be supplied and fitted by the builders.

MINING IN NOVA SCOTIA.—The Department of Mines in Nova Scotia issues a yearly report, which for the past year has just reached this country, and which has some details as to colliery working that are of interest. It appears that the output of coal was for the year 2,089,245 tons, and the total number of persons employed in the production was 5793. The collieries are not very numerous, but they vary greatly in the extent of their output. There are tables of both the men and the working days per year, and it may be said that the quantity per day varied from 400 tons to 4190 tons; but the pits worked from 76 days to 285 days in the year; and the largest colliery had a production of about 809,000 tons for the year, or more than a third of the total output of Nova Scotia. There is an interesting table of the air circulation which shows that there are variations of from 6000 cubic feet to 69,000 cubic feet of air circulating per minute through Cape Breton mines in the different months of the year, the variation being probably due to the lessened number of working days in some of the months. There are detailed reports of the different districts, and of the changes in the machinery of the collieries. The introduction of air compressor plants at the Sydney mines, the procuring of new fans such as Walker's in the Drummond colliery, which has a capacity of 200,000 cubic feet per minute, and the making of important new levels and sinkings being detailed in the reports of the sub-inspectors of mines. The Department of Mines seems to be doing good work in Nova Scotia; and it had entered into an elaborate inquiry into the causes of the fires that had occurred in Picton mines, and which interfered so greatly with the production of the district for the year. Details are given in regard to collieries there, such as the quantity and kinds of timber used in Springhill collieries in a year, details that cannot possibly be given for the great masses of mines such as in this country, which are none the less of interest. A table which details the extent of the sales of coals from the Nova Scotia mines for a hundred years traces the output from a thousand tons up to 1835, when it passed 100,000 tons for the year, and thence to 1881, when it reached 1,000,000 tons. Since that time, with an increased demand, and with better machinery at the mines, there has been a more rapid growth of the production, until the total yield from the mines has now reached 40,000,000 tons, apart from the colliery consumption. The figures given are of value, though their totals are far below those of the great coal-producing districts.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

OLD contracts are being finished off, and new ones have scarcely yet been booked, though to-day—Thursday—in Birmingham there were inquiries which presaged a fair amount of business at the ensuing quarterly meetings. Meanwhile operations at the works are being hastened in view of the Easter holidays. Prices are a little less firm on the week. Lincolnshire pigs are 44s. to 45s.; Northampton forge sorts, 41s. to 42s. 6d.; and Derbyshires, 42s. to 43s. Staffordshire cinder pigs are 36s.; part-mines, 42s. 6d.; and all-mines, 55s. to 57s. 6d. Marked bars are £7 to £7 12s. 6d.; merchant sorts, £6; and common, £5 5s. to £5 10s. Prices of sheets are kept down by the great production. Doubles are quoted £6 12s. 6d. to £6 15s., and lattens £8. In the steel trade a good deal of work is under execution, but prices are not by any means what steel masters could wish. Basic steel boiler plates continue £6 5s., and girders and angles £5 10s., while bars are £5 15s. to £6. Most of the engineering establishments are well engaged.

At the present time the advantages of modern machinery are being experienced in a gratifying manner by the Patent Shaft and Axle Tree Co., Wednesbury, to whose position a brief reference was made in my last letter. As indicating the extent of the concern, it may be stated that for the greater part of the last six months they have been giving employment to about 2000 persons, of whom 1700 are engaged in the manufacture of iron and steel wheels and axles, and over 300 at the collieries. The establishment consists of three distinct sections, namely, the Brunswick Iron and Steel and Wheel and Axle Works, the Monway Iron and Steel and Tire and Axle Works, and the Old Park Works, where bridge and girder construction is carried on. These works cover an area of nearly 70 acres, and in addition there are the collieries, which make up an entire estate of 500 acres. The assessment of the property is between £12,000 and £13,000, and last year's payment for rates and taxes exceeded £4000.

In the wheel and axle department the directors have made of late many improvements and alterations, the result of which is to increase the capacity of the works from an output of 500 pairs of wheels and axles per week to 1000 pairs. Every variety of railway wheel is made, and for their production a number of improved appliances have been erected. The new and powerful hydraulic presses which shape the bosses of the wheels out of red-hot metal are in striking contrast to the smaller presses which did service up to a few years ago. The latter possessed a power of from 80 to 100 tons each, but the principal new press is 1200 tons, and the foundations have just been dug out for one of 2000 tons. The turning and finishing shops have also been overhauled, and the fine inspection shed, 200ft. by 50ft., is among the buildings erected since the reconstruction of the company. The company also lays itself out for producing a superior quality of steel suitable for the weldless steel-tube trade, and for which the directors claim favourable comparison with Swedish steel.

An exceptionally fine plate mill is among recent additions to the plant, which will roll steel plates for boilers, bridge work, and tubes up to 7ft. 9in. in width and $\frac{3}{16}$in. to 1½in. in thickness. Some recently turned out were 35ft. in length by 40in. in width. They were trimmed with a very small amount of scrap, and were being sub-divided into lengths for conversion into steel water tubes. The mill is by far the largest plate mill in the district, and has been erected at a cost of about £15,000. Both the plate mill and the cogging mill are driven by a pair of powerful reversing engines of the newest type and of 2500-horse power. The foregoing machinery, and also mills for the production of various sections of merchant steel—girders, angles, &c.—are all under one roof, which is traversed from end to end by a travelling crane for changing the rolls and facilitating repairs. A new hydraulic testing machine of the latest type, by Buckton and Co., of Leeds, has also been recently erected, and is capable of applying a strain up to 50 tons. In the merchant iron department of the Brunswick Works, the directors have provided a new type of Siemens furnace for reheating wrought iron "pile" and billets. The furnace, which is heated by five gas producers, will in twelve hours reheat a shift of 20 tons, and effects a great saving both of fuel and of time.

A matter of considerable importance to the extensive brass foundry interests of Birmingham and district—which is the chief brass seat in the Kingdom—is the issue of the new special rules in the brass trade. A condensation of the official document follows:—Factory and Workshop Acts, 1878 to 1895. Mixing and casting of brass and of certain other alloys; special rules. Under Section 8 of the Factory and Workshop Act, 1891, and Section 28 of the Factory and Workshop Act, 1895, for the processes in the mixing and casting of brass, gun-metal, bell-metal, white-metal, delta-metal, phosphor bronze, and manila mixture. These processes are certified to be dangerous or injurious to health by the Secretary of State, by certificate dated January 1st, 1896, and published in the *London Gazette* of January 10th, 1896. Duties of Occupiers: (1) They shall provide adequate means for facilitating, as far as possible, the emission or escape from the shop of any noxious fumes or dust arising from the above-named processes. Such means shall include the provision of traps or of louvre gratings in the roof or ceiling of any shop in which such processes or either of them is carried on. In any shop, which is situated under any other shop, there shall be provided an adequate flue or shaft to carry away any fumes. (2) They shall cause all such mixing or casting shops, whether defined as factories or as workshops under the Factory and Workshop Act, 1878, to be cleaned down and limewashed once at least within every nine months. (3) They shall provide a metal basin, and a supply of water and of soap, for the use of all persons employed in such mixing or casting shops. (4) They shall not, on and after the 1st day of July, 1896, employ any female in any process whatever, in any such or casting shop, or in any portion thereof which is not entirely separated by a partition extending from the floor to the ceiling. Duties of persons employed: (5) They shall not partake of or cook any food in any such mixing or casting shop within a period of at least ten minutes after the completion of the last pouring of metal in that shop. Note: Women and persons under eighteen years of age are by the 39th Section of the Factory and Workshop Act, 1878, expressly forbidden either to take a meal or to remain during the time stated on the notice affixed in the factory or workshop, as being allowed for meals, in any casting shop; and the obligation of enforcing this section rests with the occupier.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—Business in the iron trade here continues to move on slowly, so far as any new buying coming forward is concerned, and although makers are mostly so well booked that they are under no necessity to force business at anything under their quoted rates, iron held in second hands is here and there being pushed for sale, and the general tendency is for the moment towards lessening firmness. This is much what I anticipated in previous notes, but any giving way in prices is not likely to be more than temporary, and although, until after the Easter holidays, business in all probability will continue quiet, the outlook for the future is satisfactory, and regarded with general confidence. Increasing activity is still the report throughout the engineering industries of the district, most of the leading firms having orders on their books which will carry them well over the year, and it is exceptional where establishments have not sufficient work on hand to keep them fully engaged.

The Manchester iron market on Tuesday scarcely brought together an average attendance, and there was only a slow inquiry stirring for either raw or manufactured material. Pig iron continues only in very limited demand, both consumers and merchants, as reported last week, being fully covered, and in many cases overbought for their present requirements. Makers' quoted rates remain generally steady, and where there is any giving way it is chiefly with iron held in second hands. Local and district brands are without quotable change, except that for Lincolnshire, what were makers' minimum quotations are now the full prices obtainable. Outside brands offering in this market are somewhat irregular in price. Delivered by rail at Manchester, foundry Middlesbrough averages 46s. 6d. to 47s., net cash, according to brand, and delivered Manchester Docks, can be bought readily at 45s. 6d. net cash. In Scotch iron, Eglinton averages about 47s. to 47s. 6d., and Glengarnock 48s. to 48s. 6d., delivered Lancashire ports, and about 49s. 6d. to 50s. for Eglinton, and 50s. to 50s. 6d. for Glengarnock are the quoted rates for delivery dock quays, Manchester.

In manufactured iron makers are booking moderate orders, but there is rather less firmness as regards prices. For Lancashire bars £5 10s. is not in all cases being adhered to, whilst it is exceptional where £5 12s. 6d. is being got; and Staffordshire bars are quoted £5 12s. 6d. to £5 15s., delivered here. Sheets and hoops are without quotable charge.

A fair weight of business comes forward in the nut and bolt trade, but no higher prices are obtainable.

The position in the steel trade is not so strong here as in other markets. Ordinary foundry hematites are obtainable at 57s. to 57s. 6d., less 2½, with 58s. 6d. still quoted for some special qualities, delivered here; ordinary steel billets can be bought at £4 10s., net cash; and although makers of steel boiler plates are not quoting under £6 10s. per ton, this figure is not being got on actual business, there being still sellers at £6 5s. to £6 7s. 6d., delivered in this district.

In the metal market only a moderate weight of new business is reported, but makers whose order books are well filled hold firmly to their prices. Not only is the advance reported last week fully maintained, but on brass and copper tubes ⅛d. per pound above list rates is being asked on any small orders that are being secured, although no official advance upon these descriptions of manufactured goods has yet been announced.

Messrs. T. and R. Lees, of Hollinwood, have designed an improved horizontal steam engine containing one or two special features. This engine is fitted with a patent automatic cut-off, under the control of a high-speed governor very positive in its action, by which the valve is regulated with great precision, and the steam supplied in accordance with the varying load. I may add that the right and left-hand engines of this type can be readily coupled to form a steady-running double-cylinder engine, with the fly-wheel between. The firm has also designed a very compact portable hand-power circular-saw bench, for use where steam-power is not available. The table is 4ft. by 2ft., and has rising and falling spindle for rebating, grooving, and tenoning, with a self-acting drag-motion for feeding the timber, and an adjustable canting fence is fitted to the machine. Variable speeds are provided for light or heavy work, and the machine can be operated by one or two handles, according to the thickness of sawing required; whilst it is sufficiently light to be readily removed to any part of the workshop, or to contract jobs outside. The bench can, if required, be supplied in a form suitable for steam power, with fast and loose pulleys fitted on the end of saw spindle, and without drag motion.

I was shown the other day at the works of Messrs. Henry Wallwork and Co., Roger-street, Manchester, a new boiler tube stopper—Watson's patent—suitable for either marine or locomotive boilers. This stopper consists of a rod, of special construction, with plugs at the ends, which is pushed into the leaking or burst tube from the front end, a box-spanner being fixed and held on a nut at one end of the stopper to drive the latter into position. The front joint is then quickly screwed up without removing the spanner. The plugs are slightly tapered in the body and thread, so as to enable the back plug to be readily screwed out from the front end of the tube. If required, the rods can be made hollow, and used as tubes for heated gases. These tubes have passed through severe tests with very satisfactory results, a hydraulic pressure of 600 lb. having been applied without affecting the safety of the stopper. On board ship in case of accidents, they can be applied without letting down the steam pressure, or putting out the fires, which is necessary under ordinary arrangements when a tube is burst, and I understand they have already been adopted by several large steamship and railway companies.

Messrs. Joseph Adamson and Co. have for some time past been introducing electric driving into their works at Hyde, and Mr. Daniel Adamson, one of the firm, who has visited America and the Continent with the object of making himself acquainted with the best methods adopted abroad, gave a description before the members of the Manchester Association of Engineers at their meeting last week, of the special plant they had recently put down. When, he said, they first began seriously to consider the matter of electric driving about three years ago, they required to increase the number of their travelling cranes, and found that their existing engines were not powerful enough to take the increased load that would be thrown upon them by adding the two or three cranes they required. They found that electric-driven cranes were, in other countries at any rate, considered to be more economical in various respects, than other types of cranes, and they therefore put down a combined engine and dynamo, which they considered would be large enough to drive the cranes they had in view, and leave a sufficient margin for lighting as well, and their intention was to double or treble this "unit" as further developments required. Their first three electric cranes, which was the original number they thought of introducing, worked so satisfactorily that they decided to increase the number, and as in the meantime they had also found it advantageous to increase the application of electric transmission of power in other directions, they had been compelled to change their original ideas, and had now in hand a seventy-five kilowatt dynamo, which would be coupled direct to a 100 B.H.P. Belliss engine, running 400 revolutions. Electric driving had been applied to a drilling machine, which, as originally designed by the makers, required three driving belts, viz., one for advancing the drills rapidly up to their work, one for doing the actual drilling at a slower speed, and the third for withdrawing the drills. By the application of a motor which would run in both directions they were enabled to dispense with the belts, and also the great number of pulleys, so that now, when the machine was not working, there was nothing moving in connection with it, and therefore no wear and tear. Another application of electricity was to a small sensitive drill, and although in this instance they had not dispensed entirely with belting, there was considerably less leather about the machine than about one driven in the ordinary way.

More important, however, was the application of motors to the hoists in their riveting tower, which enabled them to stop entirely about six belts, and 50ft. or 60ft. of shafting, besides giving the men something more under their control for the small adjustment of height required when riveting up shells. It also enabled them to hoist, and lower through greater distances, as when adding another ring, at a higher speed than could be done with a strap-driven hoist that was of course always working at the same speed. The belts, he might add, had been found to last longer and to break down less frequently when driven by an electric motor than when driven by a series of belts from the shop engines. One most important application of electric power had been the driving of their overhead travelling cranes. Since they had electric power at their disposal in the works, they had found it very convenient on special occasions for driving individual machines, that might be required to run night and day, or in special positions for a period. On such occasions they now only required to run during the night the comparatively small generating plant, which provided not only the power to drive the machine, but an abundance of light for the men to work by, and also enabled them to make use of the overhead cranes for moving the work when required. This dispensed with the great waste of coal and oil entailed formerly by running the large engines and all the shafting, belts, &c. Amongst the direct advantages of electric driving, he did not think they ought to look to any immediate saving in fuel although he believed this would ultimately follow its application, but the actual expenditure on fuel for power purposes alone was so small that even a reduction by a large percentage would mean very little compared with the other items of cost of production. Another advantage of electric transmission was the regularity of driving obtained by its means, and although the benefits derived from this were greater in such cases as a spinning mill, for example, than in a workshop, even in the latter the advantages of keeping up to the normal speed under the heaviest loads was sure to make a difference in the output when compared with a system of transmission which was liable to ease off when called upon for full duty, and which was subject to every change in the condition of the atmosphere.

The coal trade shows no improvement, but, if anything, the position becomes still more unsatisfactory, and I may mention as a significant fact as to the outlook for the future, that at some of the collieries stocks, with the close of the winter, are so heavy that any further accumulation of these during the summer is out of the question, with the result that pits will have to go on still shorter time than was the case last year, when the large proportion of them were not running more than three days per week. For the better qualities of round coal there is a slackening off in the demand, and it is exceptional where pits are being kept on more than four days per week, whilst prices here and there are easing down, concessions of 3d. to 6d. being made to effect clearances. Supplies of steam and forge coal continue excessive, notwithstanding the limitation of the output, with prices altogether unprofitable, not averaging above 6s. to 6s. 6d. at the pit, whilst to effect sales of anything like quantities still less has to be taken, especially in some of the commoner descriptions. As regards engine fuel, the better sorts meet with a fair demand, and at some collieries supplies are so scarce as to justify an advance on present rates, but as at other collieries the output is still fairly plentiful, any upward move is checked, and even the attempted advance in prices upon forward contracts has scarcely met with success. Common sorts move off but slowly, with no better prices ruling. At the pit mouth the better qualities of slack still average 4s. 6d., with some special sorts quoted 5s., and common slack averages about 3s. to 3s. 6d. per ton.

In the shipping trade prices continue extremely low, with a further weakening tendency, if anything. Delivered ports on the Mersey, common steam coal used for bunker purposes is readily obtainable at 6s. 9d. to 7s., and delivered Partington tips, Manchester Ship Canal, 7s. to 7s. 3d. per ton.

Barrow.—The hematite pig iron trade is brisk, and the orders booked during the past week have been quite up to recent averages. Makers are so fully sold forward that they cannot quote for prompt deliveries. They have 39 furnaces in blast, compared with 28 in the corresponding week of last year, and these furnaces represent an average output of 800 tons per furnace, all of which is going into consumption. Stocks show no increase. They stand at 303,029 tons, or 13,854 tons more than at the beginning of the year.

Iron ore is brisk at 10s. for ordinary, 12s. 6d. for best, and 14s. 6d. for Hodbarrow qualities. Spanish ore is being largely imported, and is quoted at 13s. per ton net at West Coast ports.

Steel makers are busy on heavy steel rails, on plates, and on billets and hoops. There is also a brisk business in heavy steel castings. Orders are well held in all departments, and the demand is active and likely to be maintained. Prices are steady at £4 15s. for heavy rails, and £5 2s. 6d. for steel plates.

The shipbuilding and marine engineering industry is actively employed. No new orders are noted during the week, but some commercial and Admiralty tenders which are likely to lead to business have been sent in.

Coal and coke are in brisk demand, but while coal is weaker in price, coke is the reverse. On shipping account there is a fairly good demand for coal. The shipping trade shows increased activity. Exports of pig iron from West Coast ports during last week reached 10,489 tons, and of steel 13,329 tons, as compared with 1290 tons of pig iron and 2252 tons of steel in the corresponding week of last year, showing an increase of 9199 tons of pig iron and 11,077 tons of steel. The aggregate shipments to date total up to 74,857 tons of pig iron and 100,792 tons of steel, showing an increase of 16,878 tons of pig iron and 14,662 tons of steel. Freights are still very low and unprofitable.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

Interest continues to increase in the forthcoming meeting of the Conciliation Board. There is a pretty general hope that a way will be found to prolong its existence for a further term. Coalowners have held informal meetings here and there, and, so far as can be gathered, the feeling is in favour of continuing the body. Although the miners have not had any gatherings on the subject, the utterances of their leaders may be taken as authoritative. Their attitude is simply this, they will be very glad to agree to a prolongation of the Conciliation Board provided that the present rate of wages, 30 per cent. above the 1888 standard, is accepted as the minimum. That is the difficulty, as the coalowners urge what is perfectly true, that under the existing arrangements the bulk of the collieries are being worked at a loss, while the value of coal itself has fallen from 1s. to 2s. 6d. per ton since terms were made at the close of the coal war.

Throughout the colliery districts of South Yorkshire, Derbyshire, Lincolnshire, and Notts, trade continues as unsatisfactory as ever. The early opening of the Baltic ports, of course, will soon make a difference in steam coal, but so far competition is keen and business depressed all round, with a lower rate of values than is usual at this season of the year. The weight of coal sent by rail to London, as well as to the eastern counties, is exceptionally moderate, and in the struggle for business Barnsley house coal has difficulty in holding its own against sea-borne coal, the tonnage rates by water being so much lower. South Yorkshire is suffering from the loss of certain important gas coal contracts. This drawback will be increased by the fact that the South Metropolitan Gas Company has again contracted for its supply from the Durham coalfield. House coal, through the mild weather, gets duller than ever. Quotations are as follows:—Steam coal fetches in the open market 6s. 6d. to 7s. for the best qualities; inferior sorts being obtainable on easier terms. House coal, best Silkstone, 8s. to 9s. 6d. per ton; ordinary, 6s. 9d. to 7s. 6d. per ton; Barnsley house, 7s. 6d. to 8s. 3d. per ton; thin seam from 6s. per ton upwards. Manufacturing fuel, for which the demand exceeds supply, ranges from 4s. 6d. to 5s. 6d. per ton in small nuts; screened slack making from 3s. 6d. per ton; pit slack from 2s. 6d., while smudge can be had as low as 1s. per ton. A good tonnage of coke is being sent to Derbyshire, North Lincolnshire, and Northamptonshire. Values are firm at 8s. to 10s. in owners' wagons at the works.

In the heavy industries there is no change to report, the various departments employed in military, railway, and marine material being pretty full of work, with no little pressure in one or two of the specialities. The volume of business is gradually swelling all round, but there is complaint that prices do not advance in proportion. Several of the establishments, which have presented their annual reports of late, have exhibited less margin of profit than was anticipated. The railway material business is improving in a gratifying way, although this applies more to tires, axles, springs, buffers, and the general appointments of rolling stock. Carriage, and wagon builders, although better off for work than they were six months ago, have not anything like their plant fully employed, the means of production in this branch of business having been greatly augmented, as well as in the works where military material is manufactured. There is an agreeable absence of disputes in the different Sheffield establishments; and in spite of the briskness in most of the iron and steel trades, there is no evidence of a desire to precipitate wage demands, which would interrupt the present revival. There have been times when a distinct accession of work has led the workmen's leaders to instantly demand more money. But the moral of this folly has been so frequently read in lost orders that a more moderate and sensible course is now almost universal.

A good deal of difference of opinion exists as to the condition of the lighter staple trades. It was stated the other day that the cutlery trade, the most ancient of all our businesses, was distinctly on the downgrade, and that it had within the last few months shown deeper depression than ever. Inquiry scarcely confirms this pessimistic view. It is certainly the case that in many markets, more particularly in India, German competition has cut out a great deal of Sheffield work. But it is equally certain that in the finer grades of cutlery neither the German nor American competition has been able to oust the local firms from their position. No little damage, however, has been done by the unscrupulous attaching of imitations of Sheffield marks to inferior German-made goods. But legislation is gradually overtaking this evil, and trade piracy is becoming increasingly perilous every day. Taking a general view of the situation in the lighter trades, it is impossible to avoid the conclusion that the same remark which applies to the coal, iron, and steel industries is equally applicable to cutlery, silver, and electro-plate. Business is being steadily, yet most certainly, gathered up into the hands of the larger firms, who are able to produce great quantities at low rates, and thus command the market. As the small coalowner is being persistently pressed out of the coal market, so the "little master" is finding his occupation passing to the owners of the larger and more perfectly equipped cutlery establishments. It is the same in the important silver, electro-plating, and Britannia metal departments.

The annual meeting of the shareholders of Messrs. Charles Cammell and Company, Cyclops Steel and Ironworks, Sheffield, was held on the afternoon of Wednesday, the 25th inst., at the works, Savile-street, Sir Henry Watson, J.P., D.L., presiding. The chairman, in moving the adoption of the report and accounts, stated that the profits during the last year were £141,238, being just about double the profits made in the preceding year. A dividend of 10 per cent. was declared. Perhaps, remarked the chairman, that was not quite so much as some of them expected, but with Cammell and Company the principle had always been to have plenty of money in hand. It was proposed to put £25,000 to the reserve fund, and carry forward £31,244. The purchase of the Solway Ironworks at Maryport, had been carried out on the advice of Mr. Barbour, one of the directors, who lived in the neighbourhood, and who was well competent to advise in the matter. During the past year the collieries of the company have made a very slight profit, but nothing worth mentioning. Mr. Alexander Wilson, deputy chairman and managing director, in seconding the adoption of the report, stated that the present year opened much more satisfactorily than the last, and they were all looking forward to a steady time of prosperity which would make amends for the depressed period which had just closed. Referring to the purchase of the Solway Ironworks, Mr. Wilson thought the directors had acted wisely in that transaction. Their steel works at Workington required a large quantity of pig iron, and they had bought the Solway works at a low price, which would make them practically independent in their source of supply. The retiring directors, Messrs. T. Barbour, C. Cammell, and T. W. Jeffcock, were afterwards re-elected.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

In all respects trade in this district is satisfactory, and continues to improve. Prices are fully maintained for all descriptions of iron and steel, except No. 3 Cleveland G.M.B. pig iron, and that has been somewhat easier in second hands, but that has been due to speculative operations in the warrant market, some of the "bulls" having to "unload," as they often have towards the end of a month; but nevertheless, there is not likely this month to be as much forced selling as is usual, there having been comparatively little speculative business during the last few weeks, and the fluctuations in warrants have been within such narrow limits that there has been no inducement for either "bulls" or "bears" to operate largely. Thus business has been mostly confined this month to satisfying actual needs, and the easing of the price of No. 3 is regarded as temporary.

Exports of pig iron from the Cleveland district have never in any March been as good as they are this month; they are exceedingly good, a fact which is due in some respects to the earlier re-opening of continental ports that are closed in the winter. The shipments of pig iron from the Cleveland district this month have reached 82,121 tons, as compared with 59,840 tons in February, and 55,155 tons in January, all to 25th. Under these circumstances, and taking into account also that local consumption and inland deliveries have also been very good, it is calculated that the consumption of pig iron will have exceeded the production by 3000 or 4000 tons, which will be a much better result than has been shown for several months past. Very little Cleveland iron is going into the public warrant stores, and the quantity held by Messrs. Connal and Co. on Wednesday night was 187,225 tons, or 1715 tons increase this month.

Makers of Cleveland pig iron have not quoted less this week for prompt f.o.b. deliveries of No. 3 than 38s. 6d., the figure that has steadily ruled for some time past, but early in the week some of the merchants sold small lots, and for delivery at once, at 38s. 3d. That figure, however, is not taken now, the warrant market having improved. No change has been made in any other pig iron prices, as they are little affected at any time by the fluctuations in the warrant market. No. 1 Cleveland pig iron is at 39s. 6d.; No. 4 foundry, 37s. 6d.; grey forge, 37s.; mottled, 36s. 6d.; and white, 36s., all for early delivery. M. Nos. of Cleveland hematite pig iron are firm with makers at 47s., but from merchants small quantities have been obtained at 46s. 6d. Rubio ore has been generally quoted at 12s. 9d. per ton delivered at wharves on the Tees. There has been some foundation for the rumours about the purchase of the Coatham Ironworks, which have been idle since September, 1886. It is a fact that one of the leading Cleveland ironmasters, the owner of more than one iron-making establishment, has had the question under consideration, but what the outcome will be remains to be seen. It is stated in some quarters that the negotiations are off. A well-known Middlesbrough engineer has recently been at the works in order to report upon their condition, and what will have to be done to put them in proper working order.

A testimonial has this week been presented at Southbank to Mr. Walter S. Hill, late manager of the Clay-lane Ironworks, and now occupying a similar position at the Redcar Ironworks.

The Middlesbrough Chamber of Commerce has made a special inquiry as to how far the iron and steel producers of the district have been injuriously affected by foreign competition. It appears the pig iron makers have no complaint to make. They seem to hold their own very well, and are delivering more iron now than at any previous time, even to Germany, though the production in that empire has increased with such rapid strides. But some of the producers of finished iron and steel, especially of the lighter descriptions, have lost trade, and the success of the foreign competition is in part due to the unfair manner in which British shipping and railway companies treat their own countrymen. Thus the shipping companies carry iron from Antwerp to Indian ports and the East at 2s. 6d. per ton less than they charge from Middlesbrough or London to the same ports, and that lower charge enables the foreigners frequently to secure the orders. Then British railway companies carry foreign produce at lower rates than are charged for iron of British manufacture, so that it is possible to send from

Hamburg, Antwerp, &c., say to Liverpool and Manchester, at lower rates per ton than will be accepted from this district to the same points. Attention was directed at the annual meeting of the Chamber to the fact that the longer hours worked on the Continent enabled the manufacturers to reduce costs. Where British workmen leave at noon on Saturdays the continental works are kept going till 6 a.m. Sunday, and they are only kept idle till 1 a.m. Monday, where British establishments are idle. Thus, where the continental mills are stopped at the week ends only 19 hours, the British works are idle 42, so that the continental firms get 23 hours per week more work out of their machinery.

A fair business is being done in finished iron and steel, and especially in steel rails and plates, which are showing a decided tendency upwards in value. Generally £4 15s. net at works is quoted for heavy steel rails, but in some cases £4 17s. 6d. has been asked. With respect to the report that the Darlington Steel Works were to be re-opened shortly, the assertion is not likely to prove correct, indeed it is officially contradicted. The directors have taken no steps in the matter, except that they have had an engineer to report upon the condition of the works, and his report is said to be unfavourable. It would require a large amount of money to re-start them and equip them with machinery necessary to enable them to compete with similar works more advantageously situated. It might have been expected that with such an active demand for rails, the rates of steel sleepers could also be brisk, but such is not the case—they are in comparatively poor request, as wooden sleepers are again generally used, because where many of the railways are now being constructed, the latter can be procured cheaply from the neighbouring forests, whereas steel sleepers on account of their long carriage are costly. This accounts for some of the steel sleeper plant in the district being only poorly employed. Steel ship plates are firm at £5 2s. 6d., less 2½ per cent., and steel angles £5, less 2½ per cent., f.o.t. The West Stockton Iron Mills, Stockton, have this week been offered for sale by auction by order of the Court of Chancery. They have been idle since December, 1892, but when in operation made 1100 tons of iron plates weekly. They could readily be converted into sheet mills

The engineering industry is disturbed by the general demand that has been made for advances of wages, and this has caused the inquiries to fall off, so that this week the masters have not had as active a time as for some time previously. The demand of the engineers does not err on the score of modesty, for they require no less than 3s. 6d. per week advance. Employers do not find themselves in a position to grant any such advance, as the improvement so far has been in the demand, and very little better prices have been secured. It cannot be denied that the men give them no time to get any benefits themselves from an improvement, for directly business begins to get a little brisker, they are down upon them for advances. The employers have, however, offered 1s. a week advance at once and 6d. more in July, no further change to be made this year. The men are now considering this offer. The patternmakers have claimed a similar advance in this district. The blacksmiths and strikers have sent in a demand for 2s. a week advance on time rates and 5 per cent. on piece work, and the joiners are proposing to apply for a rise. The boilermakers and iron and steel shipbuilders of the North of England claim an advance, but have not stated any specified sum, but 5 per cent. is what they think the trade warrants.

Sir W. G. Armstrong, Mitchell, and Co. are about to enlarge their Elswick works, and have bought land therefor at the foot of Water-street, Newcastle. The directors of this firm have declared an interim dividend of 5 per cent. per annum on the ordinary shares and 4 per cent. per annum on the preference shares.

The coal trade is still dull where steam qualities are concerned, but some very good contracts for gas coals have been secured within the last few days at prices which range from 6s. 3d. to 6s. 6d. per ton, f.o.b. The South Metropolitan Gas Company has ordered 700,000 tons, and an Italian order is for 800,000 tons, the North-East Coast. Coke is in very good request, with prices tending upwards; in fact, a large quantity of coke has been sold at 14s., delivered at the Middlesbrough furnaces, though there are still plenty of sellers of good coke at 13s. 6d.

The Stockton and Middlesbrough Corporations Water Board have accepted the tender of Mr. John Scott, of Cotherstone, for the construction of the Larlington Filter Bed, at £57,041 2s. 9d. The other tenderers were:—Parker and Sharp, York, £53,146 12s. 1½d.; J. Schofield, Sons, and Co., Leeds, £56,240 5s. 10d.; A. Kellett, Ealing, £57,062 14s. 5d.; Henderson and Duncan, Edinburgh, £65,698 0s. 2d.; Whitaker Bros., Horsforth, Leeds, £69,917 11s. 11d.; F. Braithwaite and Co., Leeds, £76,901 13s. 11d.; J. H. Ridley, Middlesbrough, £78,137 10s. 2d.

The coal trade of Durham and the ironstone mining industry of Cleveland have this week presented a testimonial to Mr. Thomas Bell, who for twenty-one years has been H.M. chief Mines Inspector of the district, and has now retired. There were upwards of 200 subscribers to the testimonial, which consisted of a "grandfather's clock," a silver tray, silver candlesticks, a diamond ring for Mrs. Bell, and an illuminated address. The presentation was made by Mr. Lindsay Wood. Mr. Donald Bain is his successor in the district.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE is no abatement of activity in the manufacturing branches of the iron trade, but the warrant market has got into a somewhat irregular state. Reports from the United States and elsewhere as to trade prospects are not quite so good as of late, and the demand for warrants on the part of speculators having fallen off, the market has lacked support. The "bears" are alleged to have taken advantage of this state of matters in order to depress prices, and the business in Scotch warrants in the early part of the week was large in consequence. It frequently happens that operations of this description form the prelude to an unsettled and excited condition of the market, and on one or two occasions this week there has been evidence of an uncertain feeling, which tended to arrest the course of prices. There has been a comparatively large business in Scotch warrants, which have been done between 46s. 11d. and 46s. 8d. cash, and 47s. and 46s. 10½d. one month. The demand for Cleveland warrants is quiet, and the prices are 38s. 2d. and 38s. 3d. cash. Cumberland warrants have been fairly active, with business from 48s. 3½d. to 48s. 1d. cash, and 48s. 6d. and 48s. 5d. one month.

The output of ordinary Scotch pig iron has been increased since last report to the extent of about 600 tons per week. There are now 43 furnaces producing ordinary, 35 hematite, and 3 basic pigs, the total of 81 in blast comparing with 79 in the preceding week, and 74 in the corresponding week of last year.

The demand for makers' pig iron is very active, largely for the home trade. In the past week 1700 tons of pigs were added to the stock in the Glasgow warrant stores, and some additions are also reported as being made to makers' holdings, but the total stocks in Scotland are still in good manageable compass, and their amount is not such as to occasion any anxiety.

The prices of makers' pig-iron are comparatively steady, as follows:—Govan and Monkland, f.o.b. at Glasgow, Nos. 1, 48s.; No. 3, 46s. 6d.; Carnbroe, No. 1, 48s. 6d.; No. 3, 47s.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, Calder, and Summerlee, Nos. 1, 51s.; No. 3, 48s. 6d.; Coltness, No. 1, 53s. 6d.; No. 3, 49s.; Glengarnock, at Ardrossan, No. 1, 51s.; No. 3, 47s.; Eglinton, No. 1, 48s.; No. 3, 47s.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 52s. 6d.; No. 3, 48s. 6d.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

The export demand for Scotch pigs continues small, and it is the coastwise trade to the West of England and elsewhere that accounts for the larger proportion of shipments. The quantity despatched from Scottish ports in the past week was 6956 tons, compared with 5420 in the same week of last year. Of the total there was despatched to Holland 480 tons, Belgium 45, United States 10, India 255, Australia 75, France 85, Italy 482, Germany 521, other countries 202, the coastwise shipments being 4801, against 3634 in the same week of 1895. The total shipments since the beginning of the year now reach 64,245 tons, as compared with 58,756 in the corresponding period of last year. Less than one-third of the total shipments have been sent abroad, the quantity despatched along our home coasts being 44,000 tons.

A good demand is reported for manufactured iron on the part of consumers, and the works in Lancashire are very well employed. Rather better prices on the whole are obtainable, but makers still regard the current rates as too low. In the steel trade there is much activity, and prices have been gradually advancing. Ship plates are reported to be selling at £5 7s. 6d., and some makers are quoting £5 10s. angles being £5. These prices are subject to the usual 5 per cent. discount for delivery in Glasgow district. Merchants are said to have made considerable purchases below the figures just quoted; but the firms mentioned as having done so are known to be extra large purchasers, both in the West of Scotland and the North of England, so that it is not at all unlikely that they may have been able to obtain special terms. While the quantity of steel being used is very large, the output is also on the increase, and there is the usual competition between English and Scotch makers.

The engineering branches are getting busier, and so also are brass-workers, rivet-makers, and a great variety of branches. The pipe-founders are doing well, at least in the small pipe department, and the tube makers are busy.

There is an improvement in the shipping department of the coal trade so far as the quantity of coals dealt with is concerned, the past week's coal shipments having been 124,164 tons, compared with 104,742 in the proceding week, and 119,190 tons in the same week of last year. Steam coals are in large supply and difficult to get rid of, main are dull and splint is easy. The better qualities of ell coal are in fair request, and there is a brisk demand for small coals and dross. Main coal is quoted f.o.b. at Glasgow, 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 6d. to 6s. 9d.; and steam, 7s. 6d. per ton.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

AFTER a duration of seven weeks, and a loss to the district estimated at £25,000, the Plymouth strike has been brought to an end. A test case, regarding allowances, was tried last week before the Lord Chief Justice in the Law Courts, and adjourned until Tuesday, when, in a great measure owing to the active intervention of Sir W. T. Lewis, Bart., an arrangement was brought about by which the matters in dispute will be settled by arbitration. Work was resumed on Wednesday, though it will be some time before the whole of the men can get into their working places.

It must not be forgotten that in the settlement "Mabon," Mr. Abraham, M.P., strove unweariedly for peace. Sir William's advocacy was acknowledged by a hearty vote of thanks from both parties. The arbitrator referred to is Mr. Frank James, solicitor, clerk of the Merthyr Board of Guardians, and esteemed as thoroughly impartial and well versed in colliery law.

The Welsh press is unanimous in its condemnation of the discharge note.

There is no change in the situation at present. A meeting of the miners' representatives is fixed for the 30th inst., when they are to receive a reply from the Coalowners' Association. It is to be hoped that the "note" will be withdrawn, as a general strike would be most disastrous. If, as alleged, the introduction of the "note" is a violation of the sliding scale arrangement, I do not think that there need be any fear of its being persisted in. The government of the Association has been a firm and consistent one, marked with every disposition to concede where the claims of justice have demanded it.

There is a fair demand for coal for prompt shipment, and cargoes to Bombay have again been numerous. The leading ones were as follows:—From Newport, Mon., the Induapura with 4900 tons. From Cardiff, Strathford with 6000 tons; Sheikh, 5600 tons; Ramillies, 3700 tons; Roma, 3600 tons.

The total shipment of coal from Cardiff last week amounted to 325,000 tons; Newport, foreign 45,224 tons, coastwise 21,587 tons; Swansea total 30,417 tons, all indicating a busy week. Prospects of a continuance until the holidays are fairly good for best coals. The latest report on 'Change, Cardiff, is to the effect that for some class of goods inquiry is rather backward. This includes seconds, drys, and Monmouthshire coals. The forecast as regards house coal has been quite fulfilled, and the "green winter of 1896" will figure in future annals as one of the slackest known for this class of coal for many years.

On 'Change mid-week Cardiff prices were as follows:—Best steam coal, 10s. 3d. to 10s. 6d.; seconds, 9s. 3d. to 9s. 9d.; drys, 8s. 9d. to 9s. 3d.; best Monmouthshire, 8s. 6d. to 8s. 9d.; seconds, 8s. to 8s. 3d.; best small, 4s. 6d. to 4s. 10½d.; seconds, 4s. to 4s. 3d.; drys, 3s. 6d. Closing prices, house coal, were:—Best, 10s. 3d. to 10s. 6d.; No. 3 Rhondda, 9s. 6d. to 9s. 7½d.; brush, 7s. 6d. to 7s. 9d.; small, 6s. to 6s. 2d.; No. 2 Rhondda, 7s. 6d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 6d. Swansea prices: Anthracite best, 11s. to 11s. 6d.; seconds, 10s. to 10s. 6d.; ordinary large, 8s. to 9s. Steam coal, best, 9s. 6d. to 10s. 3d.; seconds, 8s. 9d. to 9s. 3d.; bunkers, 7s. to 9s.; small, 4s. 3d. to 4s. 6d.; house coal, No. 3 Rhondda, 10s. to 10s. 3d.; No. 2 Rhondda, 8s. 9d. to 9s. 6d.; patent fuel, 9s. 9d. to 10s. 3d.

At Cardiff the patent fuel trade is rather brisk, prices, 10s. 3d. to 10s. 6d. For coke the demand steadily improves, price: furnace, 13s. to 15s.; foundry, 15s. to 16s. 6d.; best, 19s. to 19s. 6d. The pitwood market is weaker, and 15s. ex-ship is the utmost that can be obtained, sales occurring at 14s. 9d.

Cardiff prices for iron ore, which is in good steady demand, are as follows:—Best Rubio, 11s. 9d.; Tafna, 11s. 3d.; Garucha, 10s. 9d. to 11s. At Swansea Rubio is quoted at 12s. 3d. Numerous cargoes continue to arrive. The Dowlais Company had five from Bilbao, and one from Elba this week, Pyle and Blaina Co., one from Carthagena. The principal iron and steel works generally have been securing large consignments of late. The iron and steel trades continue buoyant. Cardiff Exchange report this week was to the effect that all the steel works were busy, and the production of steel rails, sleepers, sheets, and small goods had been considerably increased.

Swansea Exchange report is not encouraging. Pig iron has dropped 8d. per ton; Glasgow warrants, Middlesbrough, 6d.; and hematite, 6d. A lull is also noted in the finished iron and steel trade, and the fact has been recorded that Welsh trade has gone into other countries on account of lower prices prevailing.

The last quotations, Swansea, are:—Glasgow warrants, 46s. 9½d., cash; Middlesbrough, No. 3, 38s. 4d., prompt; hematite, 45s. 10½d.; Welsh bars, £5 10s. to £5 15s.; sheet iron, £6 15s. to £6 17s. 6d.; steel, £6 12s. 6d. to £6 15s.; Bessemer steel bars, £3 17s. 6d.; Siemens, best, £3 18s.; steel rails, heavy, £4 10s. to £4 12s. 6d.; light, £4 17s. 6d. to £5 7s. 6d.; Tin-plates: Bessemer steel coke, 9s. to 9s. 1½d.; Siemens, 9s. 1½d. to 9s. 3d.; ternes, per double box, 28 by 20 c., 16s. 6d., 17s. 6d., to 22s. 6d.; best charcoal, 12s. 6d. to 12s. 9d., according to finish of brand-wasters 6d. to 1s. less than prime. It must be noted that these tin-plates are merely nominal, for it is stated on good authority that forced sales are being made at a very low figure. Of course best brands are firmer. The shipments last week were in excess of make, being 38,664 boxes, while make was 33,690 boxes. Stocks are now at 176,417. Several shipments from Llanelly took place this week direct to Liverpool. It is reported from America that the tin-plate trade is carried on there at a loss, so hopes are held that some improvement may probably take place in the Welsh trade. At present the condition of things is unmistakably bad. In several quarters stoppages are rumoured, and announcements made that works are for sale. I do not specify these cases or enter into details, for any day may bring about a change.

Compared with this time last year the falling off is marked, and this, of course, has told on harbour totals. I see that the anthracite trade at Swansea is expanding, and some fine tonnage is due. Good orders for Germany have been booked for this class of coal.

At Briton Ferry nineteen mills were in operation last week—Vernon, four; Baglan Bay, three; Gwalia, three; Villiers, six; Earlswood Tin-plate Works, three.

A second coal seam has been struck at Cadaxton Heath by Messrs. Glasbrook Brothers. This proves to be the 5ft., and the 9ft. seam may now be expected.

The Dowlais strike amongst the fillers continues, and the introduction of new hands has led to disturbances. The company offer rewards for offenders.

The Miner's Provident Society, which commends itself to the consideration of the benevolent public as the best means for distributing relief to sufferers from colliery explosions, received this week on behalf of the Tylorstown sufferers £500 from Messrs. Carlisle, Nuna, Rider, and Canning, and £100 from the National Colliery Company.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

A BRISK demand and further advances in quotations have been the characteristic features of last week's iron business. Makers and manufacturers are well situated, and prospects may be considered very satisfactory.

In Silesia the iron trade is extremely active, orders being plentiful. The blast furnace works are fully occupied, and somewhat better prices have been realised lately. The different sorts of malleable iron are in very good call on foreign as well as on local account, and buyers willingly pay the slight advances that have been agreed upon for some articles.

There is nothing particularly interesting to be told in connection with the Austro-Hungarian iron industry, the situation of the raw and also of the finished iron department being much the same as last week. In the bar and girder trade there has been a good deal of activity recently, and the result has been a decided upward tending of prices. Officially, however, the same rates are quoted as before, but next month is sure to bring an advance in the quotations for structural iron, and, perhaps, for plates and rails also. The railway material trade is exceptionally brisk, home orders being heavy; on foreign account not much has been doing hitherto.

Business on the French iron market shows considerable improvement, large contracts having been secured in the course of the week. Pig iron is getting rather scarce, and fairly good prices have been received in many instances. The manufactured iron branch is also developing satisfactorily, foreign demand having been fairly animated, while that on local account is considered much better than it has been for some time. Quotations, though exceedingly firm in most instances, have as yet not been officially raised, but purchasers show less reserve, and in some special cases are known to have willingly paid a few francs more for bars and girders.

On the Belgian iron market the general upward tendency continues. The demand for both raw and finished iron is so strong that the works have in a number of instances hardly been able to execute the orders within the time stipulated. The advanced prices are paid without questioning. Foundry pig has been rising very rapidly of late, No. 3 Luxemburg sort standing on 53f. p.t., against 48f. p.t. on February 1st. Steel rails are in rather less active inquiry than was anticipated. Comparing the official quotations for March 1st and February 1st of the present year, an upward movement can again be perceived for almost all articles. Luxemburg forge rose from 45f. p.t. on 48f.; basic remained on 54f. p.t. Bars No. 2, free Belgian station, advanced from 125f. on 127·50f. p.t.; No. 3 from 130f. on 132·50f. p.t., for export prices likewise rose 2·50f. p.t. Girders No. 2, free Belgian station, remained on 125f. p.t.; the same, f.o.b. Antwerp, rose from 117.50f. on 120f. p.t.; angles, free Belgian station, rose from 130f. on 137·50f. p.t. Plates, both for home and for foreign demand, remained the same as before, while steel rails rose from 110f. on 112·50f. p.t. On March 1st there were 27 blast furnaces in blow in Belgium, out of 43 existing, 10 producing ordinary pig, 3 foundry, and 14 basic. Output of pig iron in Belgium was, for February and during the first two months of 1895 and 1896, as under:—

	February.		January 1st to March 1st.	
	1896.	1895.	1896.	1895.
	Tons.	Tons.	Tons.	Tons.
Forge pig	22,475	34,160	49,600	71,980
Foundry pig ..	7,685	8,120	14,505	17,110
Basic	33,350	25,520	69,000	56,210
Totals	63,510	67,800	133,105	145,300

A firm tone prevails on the Belgian coal market. For some classes of engine fuel higher prices are paid without questioning; best steam coal is quoted 12f. to 13f. p.t.; best small coal, 11·50f. p.t.; seconds, 9·50f. p.t. Coke continues to be offered at 13·50f. p.t. Import of coal amounted to 136,479 t. for January of present year, against 108,193 t. for the same month the year before; 77,028 t. came from Germany, against 53,159 t. for the same month last year. Import in coke was 17,941 t., against 32,393 t.; import from Germany into Belgium decreasing from 31,995 t. on 16,924 t. Export in coal amounted to 380,809 t., against 373,843 t.; to Germany 10,503 t. were sent, against 21,699 t.; while to France 299,813 t. were exported, against 294,793 t. in the year before. Export in coke amounted to 67,311 t., against 75,734 t.; 7550 were sent to Germany, against 15,890 t., France receiving 44,558 t., against 38,729 t.

Last week was a brisk one all round in the iron and steel trade of Rheinland-Westphalia. There is a very marked activity at the blast furnace works, most of them having secured contracts for the third and even for the fourth quarter. Prices are very firm and exhibit a decided upward tendency. The aspect of the malleable iron trade is very cheerful. In the beginning of the year, after the revival set in, there were still some mills that were only irregularly and even insufficiently occupied, but during the last few weeks the improvement has progressed so quickly and has become so general that, judging from the order books, full employment will be secured to all the mills for several months to come.

Bars sell much better than they did; the convention of the South German rolling mills has raised the price on M. 118 p.t. free Neunkirchen. Girders are very briskly called for, with prices a trifle higher than two weeks ago. The same holds for hoops. Plates of all descriptions are very brisk of sale, but attempts to raise the prices have met with but little success. Numerous orders are being received at the sheet mills. Less favourable accounts must be given of the wire business, which continues dull and depressed in the extreme, in spite of all that has been said to the contrary; foreign demand, which is specially important for the wire trade, has dwindled down to a mere nothing, the present tariffs and high prices for raw material rendering a successful competition on foreign markets almost impossible. In the different departments of the railway and engineering trade a fair amount of work is available, and the position of matters is decidedly more hopeful than it has been for a long time past.

Official reports concerning the Spanish iron industry state that the 300 existing iron ore mines, employing 12,926 men, yield an output of 5,352,253 t. iron ore, worth 19,979,559 pesetas; and 736 t. argentiferous iron ore, worth 4130 pesetas; 473 collieries with 15,174 men, and 67 brown coal works, with 562 men, produced 1,659,274 t. pit coal, worth 11,638,383 pesetas, and 48,460 t. brown coal, worth 316,330 pesetas; 17 blast furnace works, employing 9025 men, produced 123,798 t. forge pig, valued at 8,498,411 pesetas; 54,214 t. foundry pig, worth 11,049,390 pesetas; and 92,851 t. basic, worth 17,921,999 pesetas.

11th March, 1896.

5435. Transmitting Money by Post, A. E. Payne, London.
5436. Machine for Drilling Hubs, J. Clifton, London.
5437. Anchors, E. L. Walker, London.
5438. Infants' Binders, M. A. Cutting, London.
5439. Hooks and Eyes, C. J. S. Spedding.—(*J. W. H. P. Spedding, Italy.*)
5440. Tobacco Pipes, F. J. Whatton, London.
5441. Combination Shank for Cornets, W. Needham, Crewe.
5442. Holding Sheets of Glass, H. W. Braddock, London.
5443. Mechanical Stokers, J. Proctor, Manchester.
5444. Brakes for Railway Wagons, L. W. Williams, Glasgow.
5445. Haulage Clips, J. Harvey, Derby.
5446. Frames of Umbrellas and the like, G. Bowmar, London.
5447. Pendant Frames, J. E. Bryant and W. Dudley, jun., Wolverhampton.
5448. Frames for Cycles, A. W. Sutton, Wolverhampton.
5449. Taps, F. Cave, Nottingham.
5450. Needle for Making Cloth Mats, F. T. Archer, London.
5451. Hem-stitching Machines, J. Mulholland, Armagh.
5452. Carts for Distributing Water, T. Greves, Warwick.
5453. Cycle Lamps, E. Gerard, Liverpool.
5454. Parts of Photographic Cameras, J. B. Brooks, Birmingham.
5455. Departure and Arrival Indicators, J. C. Sellars, Liverpool.
5456. Weighing Packages or Goods, E. Banks, Liverpool.
5457. Brake Mechanism for Road Vehicles, J. W. Cook and C. Scott, London.
5458. Windmills, E. J. Schrock, London.
5459. Drip Cock for Steam Engines, J. A. Wright, London.
5460. Lavatory and Bath Overflows, A. F. Morrison and M. Ingram, Manchester.
5461. Hearth Blocks for Fireplaces, J. H. Goodman, Reading.
5462. Displaying Advertisements, E. G. Butler and T. E. Benson, Birmingham.
5463. Metallic Bedsteads, S. I. Whitfield, Worcester.
5464. Bicycle Holders, T. Lamb, jun., Stirling.
5465. Screens for Hotel Bars, T. Naylor and S. H. Hurst, London.
5466. Disconnecting Power Looms, A. E. Walker, Halifax.
5467. Electric Tramcars and Tramways, E. H. Hackett, Halifax.
5468. Circular Cutters, E. Richardson and G. W. Elliott, Sheffield.
5469. Archimedean Hand-drill, C. W. W. Wilson, Newcastle-on-Tyne.
5470. Apparatus for Heating Water, J. F. Wiles, Jersey.
5471. Digestive Cheese, J. B. Sincock, Bridgwater.
5472. Tobacco Pipes, W. C. Phillips, Bradford.
5473. Attachments for Chairs, O. B. Hatch and J. W. Dougall, Glasgow.
5474. Railway Wagon Brakes, J. E. Alderman and A. H. Barnett, Birmingham.
5475. Locomotive Carriages, E. J. Clubbe and A. W. Southey, London.
5476. Manufacture of Bread, W. S. and W. H. Mitchell, London.
5477. Measures for Lawn-tennis Courts, H. Bawtree, Surrey.
5478. Cleaning Bottle Stoppers, &c., F. C. Garrod, Kent.
5479. Alternating Current Electric Motors, A. S. Frazer, London.
5480. Means for Locating Leakages, W. V. Hunt, London.
5481. Kilns for Malt Drying, R. Hardy, London.
5482. Bricks, G. Power, London.
5483. Rocking Shafts, J. McAndrew, Ashton-under-Lyne.
5484. Baskets, W. J. Lyne, London.
5485. Motor, A. Hodost, London.
5486. Augers, The Sandycroft Foundry and Engine Works Company and J. Jones, London.
5487. Toy Guns, M. David and A. Davies, London.
5488. Manufacture of Boxes, R. C. Wixcey, London.
5489. Portable Household Fire Escape, H. A. Foot, London.
5490. Salicylic Acid, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
5491. Motors, Siemens Bros. and Co.—(*Siemens and Halske, Germany.*)
5492. Head Gear of Pits, C. Sebastian-Smith, London.
5493. Cutting Tool, H. Cohn.—(*D. Schoenfeld, Switzerland.*)
5494. Material for Photographic Printing, H. McClean, Croydon.
5495. Nitrogenous Substances, J. S. Wallace and J. Castell-Evans, London.
5496. Fastening the Wheel Axles of Cycles, A. S. Beyreiss, London.
5497. Automatic Stopcock, S. R. Bottone, Surrey.
5498. Folding Ladders, F. Birch, London.
5499. Sheet Metal Cans or Boxes, F. W. Feaver, London.
5500. Flanging of Tubes, G. F. Redfern.—(*F. Fuhrmann, Germany.*)
5501. Lamp Extinguishers, J. N. Lewis and T. Stubbs, Liverpool.
5502. Neckties, J. H. Clegg, Liverpool.
5503. Seating of Passengers, J. Miess, Manchester.
5504. Fastening for Shoes, &c., A. Yole, Birmingham.
5505. Hermetically Sealing Vessels, J. C. Gittins, Liverpool.
5506. Electric Accumulators, P. F. Ribbe, Liverpool.
5507. Slaughtering Animals, J. Favets, London.
5508. Hand Looms, &c., The Honourable R. Flower, London.
5509. Form of Ratchet Screw Driver, F. Partridge, London.
5510. Flower Tubes, C. C. Mallett, London.
5511. Arc Lamps, W. J. Davy, London.
5512. Cars, E. A. Sperry, London.
5513. Gloves, O. Werfel, London.
5514. Beverages, R. E. Harrison, London.
5515. Sash Fasteners, J. Wood, London.
5516. Car Starters, T. Heather, London.
5517. Advertising Devices, J. T. Bustin, London.
5518. Covers for Biscuit Boxes, E. L. Antrobus, London.
5519. Presses for Production of Coins, W. B. Challen and Taylor and Challen, Ld., London.
5520. Cranks for Velocipedes, &c., T. Shepherd, London.
5521. Providing Pistols with Butts, A. Samut, London.
5522. Preventing Re-filling of Bottles, W. F. Darcy, London.
5523. Utensil for Frying Eggs, T. H. Gaskin, London.
5524. Tires, W. Tatham, London.
5525. Gear and Friction Driving, S. Z. de Ferranti, London.
5526. Dough Kneading Machines, R. Dean, London.
5527. Handle Bars for Cycles, G. Antoine, London.
5528. Economisers for Steam Generators, H. McPhail, London.
5529. Chain Cables for Ships, &c., W. S. Simpson, London.
5530. Fasteners for the Hair, E. M. M. Mackay, London.
5531. Apparatus for Raising Water, G. S. Jones, London.
5532. Loading Silk, C. E. Puller and A. Biermann, London.

12th March, 1896.

5533. Extraction of Gold from Ores, J. B. Torres, London.
5534. Wheels, H. R. Stockman, Dover.
5535. Burnishers for Bits, W. H. Duly, Sussex.
5536. System of Combined Girders, U. Geneviève, Brussels.
5537. Automatic Telegraph Apparatus, G. Hyvert, Brussels.
5538. Unsinkable Boats, A. and A. Faure, Brussels.
5539. Stay Rod Ends, T. Griffiths, Birmingham.
5540. Section or Delivery Hose, J. L. Jones, Dublin.
5541. Drum Yarn Tester, W. Stock, Oldham.
5542. Heating of Tires, W. Mottram, Polesworth, near Tamworth.
5543. Feeding Bottle, W. F. Wood and E. C. Toller, London.
5544. Pipe, T. W. Vipond, Newcastle-on-Tyne.
5545. Steel Tires for Cycles, T. E. Weaver, Wolverhampton.
5546. Sealing Cans, R., A., W. A. Read, Liverpool.
5547. Wash-house Boilers, E. Handslip and J. Taylor, Newcastle-on-Tyne.
5548. Safety Water Boiler, E. A. Jennings, Huddersfield.
5549. Intercepting Trap for Drains, E. Codling, Manchester.
5550. Footballs, R. Young, Glasgow.
5551. Boiler Tube Stopper, T. Gibbison, Newcastle-on-Tyne.
5552. Pneumatic Tires, W. Macdonald, Glasgow.
5553. Door Knob, J. Jackson, Halifax.
5554. Shedding Motions of Looms for Weaving, W. Morris, J. Morris, J. Walsh, and H. Sharples, Halifax.
5555. Making Bedsteads, A. Lawrence, Birmingham.
5556. Filtering Apparatus, H. S. Young and C. J. Ellis, Glasgow.
5557. Overflow Apparatus for Baths, J. Shanks, Glasgow.
5558. Graters, E. Gilmore, Hamilton, Ontario, Canada.
5559. Surveyors' Tape Measure Box, B. S. Peaker, Bradford.
5560. Universal Projector, J. Haegele, Hastings.
5561. Rope Grip, W. H. A. Everett, Cambridge.
5562. Tobacco Pipe Cover, S. Smith, Norwich.
5563. Compasses for Night Marching, J. H. Steward, London.
5564. Producing Peat-fibre, E. Paté and J. A. Brion, London.
5565. Foot Guard for Railway Rails, J. K. Rile, London.
5566. Heat Radiators, J. B. Fox, London.
5567. Washboard, R. J. Hartwick and H. G. Blanchard, London.
5568. Brazed Joint Cleaning Process, W. H. Kitto, London.
5569. Perambulators, Mail-carts, &c., W. Middleton, London.
5570. Scarifying Machine for Roads, E. G. Harris, London.
5571. Apparatus for Signalling, A. W. Robinson, London.
5572. Mechanical Toy Gun or Cannon, O. Hanks, London.
5573. Fireplace, &c., S. Pollitzer and R. E. Ogilby, London.
5574. Mechanical Musical Instrument, E. Welte, London.
5575. Ships' Signal Lights and Rockets, A. Pain, London.
5576. Producing Figures in Carpets, R. Etherington, London.
5577. Stands for Bonnets and Dresses, W. Arthur, London.
5578. Cycle Chains, F. W. Golby.—(*A. Humbert, France.*)
5579. Puzzle, W. C. Owsman, London.
5580. Liquid Measuring, H. E. Smith and M. Salomon, London.
5581. Window Fastener, A. Richartz, Cologne.
5582. Wood-wool Machines, H. Klippel, Cologne.
5583. Journal for Cycles and Vehicles, C. Truman, London.
5584. Treating Carbon in Electrolytic Processes, A. Coehn, London.
5585. Manufacture of Oxybenzoic Acids, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
5586. Brake Mechanism for Cycles, O. T. Blathy, London.
5587. Vaporiser Injectors, B. Bourdallé and C. Berthemet, London.
5588. Cycle Brakes, A. E. Hench, London.
5589. Animal Feeder, L. P. Selbach, London.
5590. Device for Injecting Powder, E. Hartman, London.
5591. Production of Preserved Grain, S. Hagyi-Ristic, London.
5592. Boxes for Ambulance Bandages, W. P. Thompson.—(*E. Zillibiller, Germany.*)
5593. Water-closet Seats, W. P. Thompson.—(*E. Zillibiller, Germany.*)
5594. Commodes, W. P. Thompson.—(*E. Zillibiller, Germany.*)
5595. Bottle Stoppers, W. P. Thompson.—(*R. Porumbaru, Roumania.*)
5596. Spanners, J. B. Marshall and J. M. Moss, Manchester.
5597. Corliss Valves of Steam Engines, W. Porter, Liverpool.
5598. Braking Oil and Gas Engines, W. Thompson, Liverpool.
5599. Apparatus for Silvering Mirrors, C. L. Erlwein, Liverpool.
5600. Safety Appliances for Lamps, A. W. Brittain, London.
5601. Fittings for Water-closets, J. B. Schnitzler, London.
5602. Walking Stick or Umbrella, B. J. O'Rorke, London.
5603. Manufacture of Buoyant Pulp Ware, H. Thame, London.
5604. Apparatus for Propelling Boats, J. Kirkaldy, London.
5605. Spring Wheels, A. Kotin, London.
5606. Gas Burners, A. J. Boult.—(*E. Rousseau, Belgium.*)
5607. Wrenches, G. F. Johnson, London.
5608. Window Cleaners, W. E. Allen, London.
5609. Starching Machines, A. T. Hagen and D. McC. Cooper, London.
5610. Machines for Making Shells for Sliding Boxes, A. J. Boult.—(*The Stecher Lithographic Company, United States.*)
5611. Draining Surface for Beer Engines, C. Erb, London.
5612. Pads for Boat Seats, D. Champion, London.
5613. Camp Cooking Outfits, J. W. Mackenzie.—(*F. C. Wilson, United States.*)
5614. Field Rations Kits, J. Y. Johnson.—(*G. H. Preston and L. M. Fuller, United States.*)
5615. Treating Rice for Brewing, A. and H. Perry, London.
5616. Electrolytic Apparatus, A. E. Peyrusson, London.
5617. The Automatic Cycle Alarm, H. S. Halford, London.
5618. Increasing the Lever Power of Cranks, W. S. Simpson, London.
5619. Ammunition Hoists, Sir G. S. Clarke and G. H. Banister, London.
5620. Preparation of Coal for Fuel, C. E. O. Betts, London.
5621. Adjustable Mould Blocks of Linotypes, The Linotype Company, C. L. Ireland, and F. J. Wich, London.
5622. Pottery-ware Glaze Firing-kilns, C. Mayer, London.
5623. Balancing Two-wheeled Vehicles, T. A. Simpson, Banff.
5624. Gas Manufacturing Apparatus, E. Farnsworth, London.

13th March, 1896.

5625. Metallic Fenders, C. Meason, L. E. Wood, T. B. Davis, and A. Mawson, Birmingham.
5626. Extinguisher for Oil Lamps, S. Shaw and N. T. Dutton, Manchester.
5627. Oil Motors, W. H. Casley and A. F. Woodman, Exeter.
5628. Steam Generators, N. Soliani, London.
5629. Shears for Cutting Lawns, J. Ellis, Isle of Wight.
5630. Propelled Vehicles, Cycles, &c., J. Roots, London.
5631. Combination Necktie, A. J. Bradshaw, West Croydon.
5632. Drawing Presses, &c., D. Smith, Wolverhampton.
5633. Police Whistle, A. Robertson and G. H. McKay, Glasgow.
5634. Automatic Flushing Valve, T. Carlaw, Lanark.
5635. Collar Studs, W. Pearce, Birmingham.
5636. Steam Generator for Heating Fluids, J. Schmidlin, Manchester.
5637. Means for Illuminating Objects, Y. Schartz, Birmingham.
5638. Steering Lock for Bicycles, W. H. Bird, Wolverhampton.
5639. Stoppers for Bottles, A. Daw, Birmingham.
5640. Vacuum Dryers, H. F. Talbot.—(*O. Siedentopf, Germany.*)
5641. Obviating Noise from Engines, R. McLeod, jun., Glasgow.
5642. Preservation of Pictures, &c., C. S. Cox, Sheffield.
5643. Cylinders for Lubricators, G. H. Shakespeare, Birmingham.
5644. Treating Hides, J. A. McIntosh, Newcastle-on-Tyne.
5645. Automatic Gas Meters, C. G. Beechey, Liverpool.
5646. Horse Nosebags, G. J. Hues, Liverpool.
5647. Refrigerating Machinery, W. B. Cumming and A. Webster, Liverpool.
5648. Circular Knitting Machines, G. Sowter, Nottingham.
5649. Consuming Furnace Smoke, J. Hay and J. Montgomery, Glasgow.
5650. Seed Drills, J. W. Shore, London.
5651. Machines for Washing, H. W. Wichman, London.
5652. Wheels and Axles for Trolleys, T. Rowbotham, Manchester.
5653. Tightening Bedstead Laths, C. Horner and E. Gothard, Barnsley.
5654. Supporting Artists' Sketch Blocks, N. M. Macdougall, Glasgow.
5655. Treatment of Sewage, J. T. Wood and J. A. Brodie, Liverpool.
5656. Holders for Music, C. H. Tenniers, jun., London.
5657. Pulleys for Hoisting, J. C. W. Kjelgaard, London.
5658. Hook and Eye Fasteners, J. H. Smith, London.
5659. Securing Handles of Cycles, H. J. W. Braine, London.
5660. Cover for Tires of Cycles, W. E. Formby, London.
5661. Labels, W. E. Alexander, London.
5662. Appliance for Use of Writers, J. M. Carter, London.
5663. Churn, H. Palmer and M. Massie, London.
5664. Chairs, W. B. Crees, London.
5665. Utilising Paper Mill Sludge, J. Bradley, London.
5666. Furniture Castor, A. P. Lundberg, London.
5667. Securing Card Clothing, J. H. Kay, Manchester.
5668. Springless Safety Locks, C. P. R. Fiebig, Berlin.
5669. Preventing Illicit Abstraction from Letter-boxes, T. E. Williams, London.
5670. Fire-escapes for Domestic Use, G. Parrott, London.
5671. Wheel Rims, B. G. King, London.
5672. Ozone Compounds for Medicine, E. Langheld, London.
5673. Refining Metals, A. S. Elmore.—(*J. O. S. Elmore, India.*)
5674. Cycle Gearing, H. C. Hall, London.
5675. Oil and Gas Motor Engines, G. S. Hooker, London.
5676. Velocipedes, T. Norton, London.
5677. Bevelling, &c., Glass, A. Griffiths, Birmingham.
5678. Securing Packing Cases, S. G. Umfreville, London.
5679. Pumps, A. and W. Purvis, Glasgow.
5680. Refacing Spinning Rollers, T. Crabb and J. Wishart, Fife.
5681. Reducing the Draught of Ships, J. F. Crease, London.
5682. Jewel Cases, F. Walker, London.
5683. Recoil Machine Guns, C. H. A. F. L. Ross, London.
5684. Musical Instruments, F. E. Malke and F. H. Oberländer, London.
5685. Suspending Ladies' Skirt, L. and B. Brèlaz, London.
5686. Washing Gas, S. Hersey and Kirkham, Hulett, and Chander, Ld., London.
5687. Making Matches, W. P. Thompson.—(*B. T. Steber, United States, and W. E. Cook, Canada.*)
5688. Pace Indicators, W. P. Thompson.—(*A. B. Holson, United States.*)
5689. Sorting Chips, W. P. Thompson.—(*N. M. Jones and R. S. Talbot, United States.*)
5690. Cesspools, W. P. Thompson.—(*E. de Harven, Belgium.*)
5691. Clutches, J. J. Hooker, Manchester.
5692. Appliance for Use with Ferrets, R. B. Kellet, Liverpool.
5693. Incandescent Gas Lamps, G. Himmel, Liverpool.
5694. Cocks and Valves for Bottles, J. Bengué, London.
5695. Mount for Photographic Albums, M. G. Amson, London.
5696. Means for Toasting Bread, &c., W. H. Aish, London.
5697. Stands for Kitchen Utensils, H. A. W. Candler, London.
5698. Carriage Apron and Canopy, G. Volland, London.
5699. Photographic Apparatus, B. Acres, London.
5700. Cage, J. S. Wyndham, London.
5701. Windows, H. Selk, London.
5702. Tubulous Steam Boilers, J. Jardine, London.
5703. Arc Lamps, A. J. Boult.—(*W. B. Jolles and E. H. A. H. Ritter von Nollendorf, Austria.*)
5704. Sharpening Tools, W. Kraus, London.
5705. Insecticide, J. N. Spence, London.
5706. Apparatus for Cisterns, &c., A. J. Blackburn, London.
5707. Jacquard Apparatus, A. J. Boult.—(*M. Kemmerich, Belgium, and O. Weese, Germany.*)

14th March, 1896.

5708. Gaiter, W. Ward, Birmingham.
5709. Window Sashes, W. Johnson, Shetland.
5710. Bells for Doors, B. Ray and J. W. Harness, Grimsby.
5711. Scouring Material, A. J. Jacobs, Bristol.
5712. Production of Fast Colours, J. Barnes, Accrington.
5713. Boot Trees, A. W. Brewtnall, Manchester.
5714. Stoves, W. T. Crooke and C. J. Saunders, Sheffield.
5715. Pinless Clothes Line, J. H. Wharton, Liverpool.
5716. Affixing Down Pins, A. H. Woodward and F. A. Willmott, Birmingham.
5717. Brackets, H. Tibbins and A. O. Morley, Birmingham.
5718. Shortening Driving Ropes, S. J. Rivett, Manchester.
5719. Heating Apparatus, T. Arnold, Manchester.
5720. Flower Clip or Holder, J. E. Atkinson, London.
5721. Hand Tackers, W. H. Dorman, Stafford.
5722. Toy Bricks or Blocks, F. Green and J. H. Lake, Exeter.
5723. Sealed Gas Reversing Valves, G. A. Daniel, Monmouthshire.
5724. Flyer for Spindles, J. Knox and J. Orr, Belfast.
5725. Indicating Names of Railway Stations, J. C. Buchanan, London.
5726. Steam Engines, W. B. Crichton, Bradford.
5727. Butter Churns, A. E. Frost and The Dairy Outfit Company, Ltd., London.
5728. Cycle Saddles, L. H. Curtois and W. H. B. Brook, Lincoln.
5729. Self-supporting Golf Carrier, D. T. Thring, Bedford.
5730. Stoves for Heating Water, J. Major, Manchester.
5731. Operating Liquid Elevators, T. Leech, Lancashire.
5732. Cisterns and Taps, J. Carpenter and J. S. Pearce, Southampton.
5733. Hanging Pictures on Walls, A. Brier, Manchester.
5734. Hauling Railway Vehicles, H. L. Marlett, London.
5735. Refrigerators, M. J. McNeil, London.
5736. Feeding Thrashing Machines, F. Needley, Lincoln.
5537. Fixing Spirit Glasses, A. W. and S. Butterfield, Oldham.
5738. Gas Regenerative Furnaces, E. Johnson and J. Thompson, Lemington-on-Tyne.
5739. Solutioned Repair Patch, A. Frost and W. J. Cordener, Ireland.
5740. Distributing Artificial Manure, A. Burns, Glasgow.
5741. An Adding Appliance, G. A. Vetch, Glasgow.
5742. Spoke-bending Apparatus, E. Leadbeater and G. Elliot, Sheffield.
5743. Cinder Shifter or Separator, S. Willoughby, London.
5744. Box, E. W. Smith, London.
5745. Message Board or Apparatus, B. M. O'Reilly, Dublin.
5746. Steam Engines, H. Cautherley and T. Birtwistle, London.
5747. Deep Well Pumps, J. Ralphs, London.
5748. Power Propelled Vehicles, F. W. Lanchester, London.
5749. Extracting Albuminous Substances, D. Finkler, London.
5750. Cotton-holder for Sewing Machines, C. Mace, London.
5751. Cycle Supports, W. Webber, London.
5752. Electro-motor, J. Perry, London.
5753. Crosleigh Coal Pedestal or Bunker, F. J. Cross, London.
5754. Argand Gas Burners, W. H. Harvey, London.
5755. Forging of Screws and Bolts, H. P. Boyd and P. Burt, London.
5756. Drying and Cooling Grain, &c., J. Pannevis, London.
5757. Preventing the Overheating of Shafts, J. S. Fitzpatrick, London.
5758. Chronophotographic Apparatus, F. Gossart, London.
5759. Movable Deviced Surface Bodies, W. Symons, London.
5760. Road Vehicles, T. Briggs, London.
5761. Ceramic Products, C. and H. Riessner, E. Stellmacher, and R. Kessel, London.
5762. Handles for Vessels, C. E. Challis, London.
5763. Pneumatic Tires, W. F. Williams, London.
5764. Pneumatic Tires, W. F. Williams, London.
5765. Pneumatic Tires, W. F. Williams, London.
5766. Drying Fabrics, La Société Anonyme dite "Blanchisserie et Teinturerie de Thaon," London.
5767. Seamless Metallic Tubes, E. Pilkington, Birmingham.
5768. Liquid Meters, W. M. Fowler, London.
5769. Colour Printing, J. Martin and V. D. Knowles, London.
5770. Stamp Batteries, W. Foggo, London.
5771. Manufacture of Steel Tubes, W. Starley, London.
5772. Manufacture of Ceramic Stone Objects, L. A. Garchey, London.
5773. Obtaining Motive Power, G. Robinson and C. D. Tustin, London.
5774. Polisher for Silk Hats, W. S. Simpson, London.
5775. Appliance for Hoppling Mares, T. Castle, London
5776. Ferrule Tip for Umbrellas, &c., A. Barnett, London.
5777. Manufacture of Lock Nuts, H. B. Hopewell, London.

16th March, 1896.

5778. Automatic Fountains, P. C. Jones, Guildford.
5779. Telephone Switchboard, D. McNamara, Dublin.
5780. Skips, J. Crossley, Manchester.
5781. Coating Iron with Zinc, S. O. Cowper-Coles, Manchester.
5782. Flax Hackle, J. Carroll, Belfast.
5783. Pen or Pencil Holder, A. E. Gilbert, Whitley, Northumberland.
5784. Clamps for Lathes, H. Meynell and G. Wade, Wolverhampton.
5785. The Smokers' Pocket Companion, J. Hough, Croydon.
5786. Burning Small Coal in Fire-grates, H. A. Kent, Ringwood.
5787. Steam Engines, W. R. Cummins, Fife.
5788. The "B" Combination, H. C. Backhouse, Dundalk.
5789. Photographic Burnishing Machine, T. S. Hargreaves, Clitheroe.
5790. Manufacture of Fuel, P. R. de F. D'Humy, Liverpool.
5791. Production of Lubricants, P. R. de F. D'Humy, Liverpool.
5792. Manufacture of Soap, P. R. de F. D'Humy, Liverpool.
5793. Disinfectants, &c., P. R. de F. D'Humy, Liverpool.

5794. Insulating Material, P. R. de F. D'Humy, Liverpool.
5795. Fire-lighters, P. R. de F. D'Humy, Liverpool.
5796. Manufacturing Briquettes, P. R. de F. D'Humy, Liverpool.
5797. Metal Polishers, P. R. de F. D'Humy, Liverpool.
5798. Tackle Box, D. R. Clark, Glasgow.
5799. Drilling Tools, G. Harrison and E. Fleming, Halifax.
5800. Cycle Saddles, P. A. Martin, Birmingham.
5801. Enclosure or Case for Cycles, R. H. Hepburn, Birmingham.
5802. Weighing and Mixing Machines, B. H. Uhlig, Berlin.
5803. Sifting Machines, C. A. Israel, Berlin.
5804. Cranes, &c., B. B. Dadley, London.
58 5. Two-wheeled Vehicles, R. E. Baker, Dublin.
5806. Furnace Fronts for Steam Boilers, J. Howden, Glasgow.
5807. Safety Catches for Coal-pit Cages, T. H. Eddleston, Wigan.
5808. Casting Tops on to Cast Iron Fenders, J. Crawford, Dudley.
5809. Women's Sanitary Band, G. Thrailkill, London.
5810. Sewing Machines, W. H. Harrap and W. H. Cottam, London.
5811. Cycle Stand and Home Trainer, V. H. Norman, Great Yarmouth.
5812. Writing Appliances for Reporters, W. Milne, Glasgow.
5813. Production of Acetylene Gas, T. Holliday, London.
5814. Gas and Oil Motors, F. W. Lanchester, London.
5815. Making Nitrate of Ammonium, G. Craig, Glasgow.
5816. Saddles, W. Matthews, Liverpool.
5817. Producing Designs upon Surfaces, E. J. and E. Lee, Leeds.
5818. Knife Sharpener, R. H. and J. F. Shaw, Manchester.
5819. Machinery for Making Tubes, E. Atkinson, London.
5820. Cup Hooks, J. A. Crane, C. E. Thomas, and J. Whitehead, Birmingham.
5821. Attaching Sticks to Umbrellas, J. G. H. Percy, Llanelly.
5822. Filtering Feed-water, D. A. Quiggin, Liverpool.
5823. Ruling Pen, E. Mann and C. Blodig, London.
5824. Bands for Holding Persons, J. J. Wilson, Birmingham.
5825. Playing Golf, E. P. Davis, London.
5826. Nosebags, W. H. Hall and J. Pritchard, London.
5827. Fire-lighters, J. Maynes and C. L. Watchurst, London.
5828. Tires, J. Turns, London.
5829. Flower and Ticket Holder, J. White, London.
5830. Slicer and Grater for Vegetables, T. R. Watson, London.
5831. Game, J. L. Lardner, London.
5832. Automatic Self-locking Tap, A. Postlethwaite, London.
5833. Cotton Cleaning Mechanism, J. D. Morel, London.
5834. Duplicate Games of Cards, W. T. Johnson, London.
5835. Zithers, W. Eschemann, London.
5836. Trimming Vegetable Fibres, M. S. Macdonald, London.
5837. Shafting Pulleys and Fly-wheels, W. Griffiths, London.
5838. Road Skate, W. Griffiths, London.
5839. Cutting and Moulding Presses, L. A. Garchey, London.
5840. Letter-boxes, Alms-boxes, &c., H. Gibbons, London.
5841. Pocket Stoves, Right Hon. D. M. B. H. Cochrane, London.
5842. Picture and similar Frames, A. Guttenberg, London.
5843. Regenerative Petroleum Lamps, F. Ludwigs, London.
5844. Preparing Soluble Starch, J. Kantorowicz, London.
5845. Extracting Gold from Ores, J. B. Torres, London.
5846. Boots, J. S. King, London.
5847. Fenders for Tramway Cars, &c., G. Beit, London.
5848. Cooling Grain, W. Byers, London.
5849. Water Softening Apparatus, F. H. Tyacke and C. E. Gittins, London.
5850. Tee Fitting for Tubes, F. Dye, London.
5851. Connecting Pipes Together, A. T. Harris, Alperton.
5852. Hat Cover or Protector, A. Rattner, London.
5853. Combination Tool, G. Hughes.—(*H. Hunt and H. Hunt, jun., United States.*)
5854. Brakes, W. P. Walker, London.
5855. Grinding Machines, J. Coyne, London.
5856. Steam Boilers, D. Purves, London.
5857. Colouring Matters, H. H. Lake.—(*Farbwerk Mühlheim, Germany.*)
5858. Colouring Matters, H. H. Lake.—(*Farbwerk Mühlheim, Germany.*)
5859. Supplying Disinfectant to Urinals, W. Hanlon, London.
5860. Motors, S. J. Ledin, London.
5861. Advertising Devices, A. Palmer and G. G. O'Brien, London.
5862. Evaporating Liquids, F. Hartmann, London.
5863. Life-saving and Swimming Belt, J. Chisholm, London.
5864. Draught Excluders, C. Bossen and A. Burghardt, London.
5865. Chime Clocks, A. J. Boult.—(*R. E. Gunther, Canada.*)
5866. Sprocket Chains, B. F. Sparr and F. K. Partric, London.
5867. Bearings, B. F. Sparr, London.
5868. Burners, A. Rose, London.
5869. Bottle Stoppers, J. D. Bushell, London.
5870. Expanding Chucks, W. A. Elliston and C. J. Jones, London.

17*th March*, 1896.

5871. Gauge for Steam Boilers, J. McLaren, Dersingham.
5872. Lift, J. McLaren, Dersingham.
5873. Additions to Parts of Umbrellas, C. Alexander, Birmingham.
5874. Carbon Pencils for Arc Lights, T. C. Hepworth, London.
5875. Stopper Labelling Machine, W. Browne, Horley.
5876. Cuff, H. J. Robbins, London.
5877. Chisel, A. Bourne, Croydon.
5878. Showing Calculations of Figures, A. Ganderton, Birmingham.
5879. Valves, C. H. Holgate, Leeds.
5880. Gilling Fibres, F. W. and C. Greenwood, Halifax.
5881. Tramcars, H. F. Christie, Halifax.
5882. Files, W. Junge, London.
5883. Sizing Machines, W. E. Heys.—(*J. Cuquelin, France.*)
5884. Switches, R. Brymer, Manchester.
5885. Cuff Guard and Protector, J. G. Williams, Manchester.
5886. Fastening Covers of Tires, &c., A. E. Hall and J. W. Sadler, Bootham.
5887. Otter Boards for Surface Water Fishing, J. Reid, Glasgow.
5888. Preacher's Aid, W. J. Potter, Essex.
5889. Machines for Embroidering Cloth, A. Gass, Belfast.
5890. Toys, J. B. Howard.—(*Uhlig and Schwerin, Germany.*)
5891. Driving Mechanism for Cycles, L. N. Dyhrberg, W. W. Curties, and A. Crum, London.
5892. Pneumatic Tires, A. L. Smith, Manchester.
5893. Power and Spray Ejector, R. H. Cox, Dundalk.
5894. Pneumatic Wheel-acting Air Pump, S. Hadland, Leamington.
5895. Cycle Friction Wheel Brake, W. J. Smith, Sheffield.
5896. Elastic Wheel Tires, &c., J. T. Southworth, Manchester.
5897. Opening Closed Cans, G. H. Stechman and G. J. Robohm, Manchester.
5898. A New Parlour Game, H. W. Bromfield, Bristol.
5899. Tin Openers, G. W. Elliott and E. Richardson, Sheffield.
5900. Chimney Pots, J. Hargreaves, Manchester.
5901. Printed Designs upon Fabrics, A. A. Kuenemann and F. D. Haddon, Manchester.
5902. Advertising Lamp, B. McDermott, London.
5903. Furnace Firebars, E. Edwards.—(*B. Fröhlich and Co., Germany.*)
5904. Adjustable Sash Balance, R. K. Brown, London.
5905. Gas Generator, G. Webb and J. W. Kelly, London.
5906. Cricket Gloves, T. H. and G. W. L. Short, London.
5907. Crushing Mill, F. A. Huntington, London.
5908. Pencil Sharpening Machines, B. J. B. Mills.—(*The A. B. Dick Company, United States.*)
5909. Golf Cleeks, A. Taylor, London.
5910. Naval Chess, H. W. H. Helby, Chatham.
5911. Typewriting Machines, J. D. Daugherty, London.
5912. Plough Tackling, R. A. Kellaway, London.
5913. Garment Holders, W. Nolan, Birmingham.
5914. Letter-boxes, H. Searle, London.
5915. Cleaning Tramway and like Rails, H. Searle, London.
5916. Treating Coke for Transport, F. A. MacKinnon, London.
5917. Couplings for Shafting, G. A. Bateman, London.
5918. Toilet Preparation, H. Priester, London.
5919. Machines for Cleaning, &c., Grain, G. Twinn, London.
5920. Hooks and Eyes, C. Standish, London.
5921. Delivery of Checks or Tickets at Exhibitions, T. Shepherd and The Simplex Cash Register Syndicate, London.
5922. Lock, C. F. Westoby, London.
5923. Lacing Hooks, E. Kempshall, London.
5924. Plastic Materials, E. Kempshall, London.
5925. Covering Lacing Hooks, E. Kempshall, London.
5926. Apparatus for Covering Eyelets, E. Kempshall, London.
5927. Eyelets, E. Kempshall, London.
5928. Photographic Cameras, H. H. Lake.—(*Automatic Camera Company, United States.*)
5929. Interchangeable Gear for Cycles, J. Tixhon-Laguesse, London.
5930. Mudguards for Cycles, H. Coyle and M. Coyle, London.
5931. Cycle Gearing, O. Badge, London.
5932. Stopping Tramcars, A. J. Higgins and A. J. Barnes, London.
5933. Pistons, J. Pollit and E. Wigzell, London.
5934. Toy, F. C. Haste, London.
5935. Valves or Cocks, W. Davey, London.
5936. Cycle Gear Cases, R. Chaplin, London.
5937. Finger Protector or Cap, J. Dreyer, London.
5938. Regulating Device for Incubators, J. Wright, London.
5939. Steering Mechanism for Cycles, H. Burstow, London.
5940. Labels, G. H. Hallam, London.
5941. Cotton Reels, W. Smith, London.
5942. Chains for Cycles, J. Boes, London.
5943. Engines with Slide Valve Gear, W. Schmidt, London.
5944. Tobacco Pipe Cleaner, A. A. Ashby, London.
5945. Apparatus for Cleaning Gulleys, F. L. Decairie, London.
5946. Devices for Drawing Spikes, H. N. Lewis, London.
5947. Scale Measures for Cloth, &c., J. I. Wagner, London.
5948 Joints, G. J. Carson, London.
5949. Machine for Abrading Covers, W. H. Staynes, London.
5950. Boxes and Canisters, W. R. Comings, London.
5951. Suspension of Motors, J. Devonshire.—(*N. C. Bassett, United States.*)
5952. Furnace Fronts and Doors, A. C. Whittome, London.
5953. Purifying Molasses, &c., C. F. Kastengren, London.
5954. Cycles, L. C. Papenfus and L. Loewenthal, London.
5955. Utilisation of Waste Products from Iron and Steel Industries, W. E. Adeney and W. K. Parry, London.
5956. Washboards, J. T. Sargent, London.
5957. Washboards, J. T. Sargent, London.
5958. Machine for Sharpening Razors, D. Thomson, London.
5959. Vehicle Wheel Bearing, J. Pettinger, London.
5960. Appliance for Saving Beer Workings, A. B. White, London.
5961. Combined Milk Jug and Sugar Basin, C. S. Pearson, London.
5962. Tea-pots, &c., E. C. Stimson, London.
5963. Lowering, &c., Ships' Boats, J. Lee, London.
5964. Flower-pots, H. Iken, London.
5965. Steam Generators, J. A. I. Claudon, London.
5966. Horseshoes, G. H. Jantzen, London.
5967. Bicycles, W. A. Osborn, London.
5968. Bottles, M. A. F. Young, London.
5969. Embroidery, M. H. Le François, London.
5970. Self-acting Steering Apparatus for Boats, J. Macé, London.
5971. Bicycles, &c., W. P. Thompson.—(*C. S. Travis, United States.*)
5972. Steam Valves, W. P. Thompsom.—(*J. L. Judge, United States.*)
5973. Compressing Wood, &c., A. and S. de Pont, Manchester.
5974. Air Ventilating Apparatus, J. Backhouse, jun., Liverpool.
5975. Mincing Machines, F. W. Follows, Manchester.
5976. Storing Acetylene, E. Appleby and H. F. Harris, London.
5977. Clocks, L. J. Smith, London.
5978. Washing Boards, G. C. Marks and F. W. Thomas, London.
5979. Axle Arms, F. R. R. Day, London.
5980. Switches, A. J. Bonnella, London.
5981. Combination Gardening Tools, E. A. S. MacMunn, London.
5982. Preservation of Food, &c., H. Higgins, London.
5983. Locking Devices for Boxes, A. J. Boult.—(*L. G. Bierling, Germany.*)
5984. Manufacture of Artificial Fuel, W. W. Holmes, London.
5985. Water-tube Marine Boilers, H. Göhrig, London.
5986. Glove, J. H. Loewenstine, London.
5987. Treatment of Cellulose Compounds, S. W. Wilkinson and The Grove Company, London.
5988. Grain-cleaning Machines, F. Seereiner and A. Misky, London.
5989. Mantles for Incandescent Gas Lighting, T. M. Ash and H. N. Weldon, London.
5990. Bird-houses, &c., G. Walker.—(*N. L. Chrestensen, Germany.*)
5991. Fencing, &c., C. Horton, Birmingham.
5992. Photographic Emulsions, H. Wandrowsky, Cologne.
5993. Castors, H. Kinsey, Swansea.
5994. Joints of Pipes for Sewers, &c., E. Codling, Manchester.

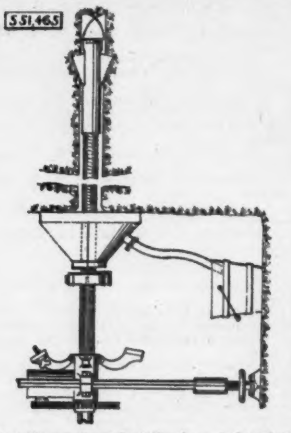
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

551,465. Dust Arrester for Mining Drills and Reamers, *R. H. Elliott, Birmingham, Ala.—Filed July 31st*, 1895.

Claim.—A dust arrester for use in drilling or reaming bore holes, which comprises a hollow truncated cone loosely mounted on the drill spindle, and provided with a fringe on the face of the base thereof, adapted to fit snugly against the face of the mineral about the bore hole, means for holding the said cone in position against the said mineral, and an orifice for the escape of the dust from the lower portion of said cone, substantially as described.

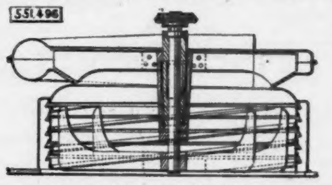
551,465



551,496. Centrifugal Grain Separator, *F. F. Landis, Waynesborough, Pa.—Filed August 19th*, 1895.

Claim.—(1) The combination, with a cylindrical grain separating chamber having an inlet opening for straw at its bottom and formed of a series of superposed rings having passages between them and lips arranged below the said passages, of means for whirling around the straw in the chamber, and guiding devices for causing the straw to pass upwardly through the chamber, substantially as set forth. (2) The combination, with a cylindrical grain separating chamber having an inlet opening for straw at its bottom and formed of a series of superposed rings having passages between them and lips arranged below the said passages, of a discharger arranged on top of the said chamber and operating to draw a current of air through it and through its passages, and means for whirling around the straw in the chamber, substantially as set forth.

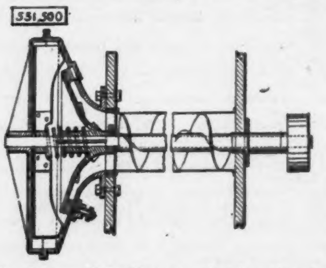
551,496



551,500. Rethrasher and Elevator for Tailings, *F. F. Landis, Waynesborough, Pa.—Filed August 28th*, 1895.

Claim.—(1) The combination, with a conveyor spout, and a casing secured over one end thereof, and provided with a conical portion and a delivery passage at its periphery; of a shaft passing through the said spout and casing and provided with means for revolving it, a spiral conveyor secured on the shaft inside the spout, a pneumatic discharger secured on the shaft inside the said casing, and a spring-pressed rethrashing disc splined on the shaft between the said conveyor and discharger, substantially as set forth. (2) In a rethrasher for tailings, the combination, with a chamber provided with an annular channel, a ring provided with teeth and let into the said channel, adjusting plugs screwed through the side of the chamber behind the ring, and studs provided with nuts and operatively connecting the said ring with the plugs; of a revoluble rethrashing disc having teeth at its periphery opposite the aforesaid teeth on the ring, substantially as set forth. (3) The combination, with a discharger casing having a rethrashing chamber at one side, of a shaft provided with a stop, a discharger secured on the said shaft, a rethrashing disc splined on the said shaft, and a spring interposed between the said discharger and disc and operating to press the disc against the said stop, substantially as set forth.

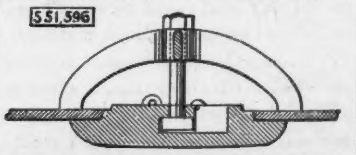
551,500



551,596. Hand Hole Plate for Steam Boilers, *E. C. Myrick and G. C. Doeg, Providence, R.I.—Filed June 26th*, 1895.

Claim.—(1) A hand hole plate provided with a mortise *a*, overhanging flanges a^1, and perforated ears *f*, substantially as described. (2) A hand hole plate provided with a mortise *a*, overhanging flange a^1, perforated ears *f*, and lug *h*, substantially as described. (3) The combination with a hand hole plate provided with a mortise having overhanging flanges of perforated lugs adjacent to the ends of said flanges, a bolt having a head engaging said flanges, and a pin passing through said lugs, substantially as described.

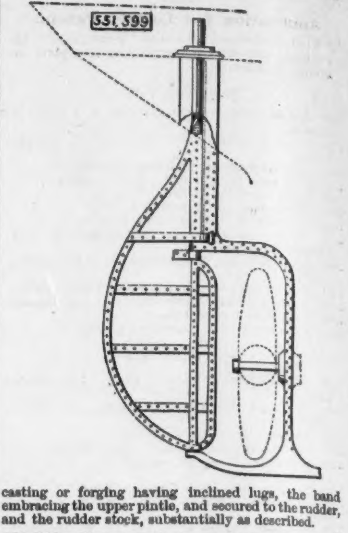
551,596



551,599. Stern Frame and Rudder for Vessels, *J. R. Oldham, Cleveland, Ohio.—Filed March 23rd*, 1895.

Claim.—The combination with a vessel, of the stern frame comprising the lower forward portion and the upper rear portion, the horizontal connection formed with a gudgeon, of the rudder having a forward extension, the pintles, the rudder stock, the stop casting or forging having inclined lugs, the band embracing the upper pintle, and secured to the rudder, and the rudder stock, substantially as described.

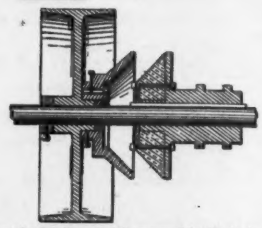
551,599



551,760. Clutch, *G. H. Gere, Grand Rapids, Mich.—Filed December 12th*, 1894.

Claim.—(1) A clutch comprising frictionally operated clutch members and centrifugally operated positive clutch members, substantially as described. (2) In a clutch, in combination with the driving and driven members of a friction clutch, a centrifugally operated pawl pivoted to one member of said friction clutch, and projections on the opposite member of said friction clutch to engage said pawl, substantially as described. (3) In combination, a shaft, a pulley loosely mounted upon said shaft, collars secured to said shaft at opposite sides of said pulley, the driven member of a friction clutch secured to the hub of said pulley, a centrifugal pawl pivoted to said friction member, a spring engaging said pawl, an adjusting screw engaging said spring, a longitudinally movable sleeve splined upon said shaft, the driving member of said friction clutch mounted upon said sleeve, and bolts securing said driving member to said sleeve, said bolt heads being adapted to be engaged by said pawl, substantially as described.

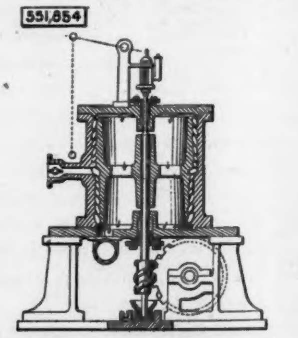
551,760



551,854. Engine, *A. Desgoffe, Odessa, Russia.—Filed November 10th*, 1891.

Claim.—(1) In an engine, the combination of a plurality of bodies provided with opposing surfaces, each provided with continuous threads, the threads on the opposing surfaces being inclined to cross each other, and increasing in capacity from the inlet to the outlet. (2) In an engine, the combination of a plurality of bodies provided with opposing surfaces, each provided with continuous threads, the threads on the opposing surfaces being inclined so as to cross each other, and increasing in inclination from the inlet toward the outlet passage, the average or medium inclination of said threads forming, preferably, an angle of seventeen degrees forty minutes.

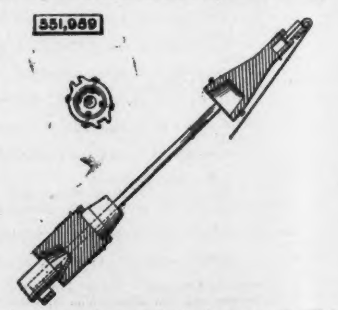
551,854



551,989. Pile Driver Hammer, *J. Munro, Astoria, Oreg.—Filed August 3rd*, 1895.

Claim.—In a pile driver, the combination of a hammer having in its lower portion a vertical frusto-conical socket, of a follower having seated in its upper end a removable non-metallic block formed with a frusto-conical portion adapted to enter the said socket, and with a lower cylindrical portion of too great a diameter to enter said socket, said follower having also apertures through which a suitable implement may be introduced to remove the said block, substantially as specified.

551,989



WAGES IN THE ENGINEERING TRADE.

By J. STAFFORD RANSOME.

I.—THE GREAT INEQUALITY IN RATES.

CERTAIN recent events, notably the strikes on the Clyde and at Belfast, the Report of the Committee of the British Iron Trades Association on Foreign Competition, various questions raised on Government contracts in the Houses of Parliament, and the correspondence in the *Times* about shipbuilding contracts, have brought into prominence the question of the wages paid in this country to the operatives employed in engineering works.

The interesting feature in this question does not lie so much in the comparison between British and foreign wages, as between the different rates paid in different parts of Great Britain for more or less similar work to a more or less similar class of men. This variation is very great, and there is no sign of any alteration in prospect. The so-called "levelling-up" tendency of Trades Unionism, of which one hears so much, on the one hand, and the levelling-down policy with which the masters are credited, on the other, appear to be equally powerless to bring about an equalisation of rates in engineers' shops in anything like the degree which is noticeable in all other countries.

It is generally assumed that this state of things is to be deplored on account of masters where wages are high being handicapped by it. But I do not think that this necessarily follows, for although individual masters may be hit hard in endeavouring to compete with firms better situated than themselves, the theoretical remedy is that such masters should put up their factories in localities where labour is cheaper. No doubt it is often extremely difficult for firms who are already established in one locality to remove their works to another; but the economist's obvious reply to this will be, that if they cannot maintain a demand for their products at profitable prices, they must finish by going to the wall, and so they undoubtedly do. It does not, however, follow from this that firms situated where labour is high cannot make their manufacturing pay, as many of the best known firms in the country are successfully working under such conditions.

In endeavouring to get at the real reasons for the absence of equalisation of wages, the questioning of men who ought to know something of the matter is usually attended by no results beyond the widest of generalities. The favourite stock methods of accounting for the present state of things are:—First, that the trades unions have forced up the wages in localities where they are strong; and secondly, that living in the big towns is much more expensive than in the small ones, and so wages are proportionately higher in the former. Unfortunately, however, neither of the above apparently plausible theories will account for the actual state of things. The first is negatived by the fact that in many of the localities where the trades unions are strong, wages are much lower than in others where their influence is weak. The second suggestion, while true enough in a general sense, is not sufficient in itself to account for anything like the difference which exists, and often it is found that the rates of wages are not at all proportionate to the size of the town.

Before going into any comparison of wages, however, it is well to run through the various trades which are followed by the hands employed by manufacturing engineers and iron shipbuilders. In all, these two industries, which are so mixed up as to be almost considered as one, comprise some fifty trades and sections of trades, and among them may be noted: angle iron smiths, angle iron strikers, boat builders, boiler men, brass finishers, brass moulders, cabinet makers, caulkers, chippers, coppersmiths, cranemen, enginemen, dressers, erectors, felters, fettlers, firemen, fitters, flangers, grinders, hammermen, hand drillers, holders-up, iron loam moulders, iron sand moulders, joiners, light and heavy platers, machine borers, machine drillers, machine screwers, millwrights, outworks men, packers, painters, pattern-makers, planers, plumbers, polishers, punchers, red leaders, riggers, riveters, sail makers, saw mill men, spar makers, smiths, strappers, strikers, tool fettlers, turners, and a host of labourers, helpers, boys, and apprentices attached to the various sections.

Among the trades enumerated above there are, no doubt, several which, dealt with in the abstract, might be said to have nothing whatever to do with engineering work, but large numbers of such men are employed by engineering and shipbuilding firms, and their work being so interwoven with that of the mechanic proper, it is difficult to ignore them when treating the subject. To schedule their various rates of wages on anything like a comprehensive scale, however, would merely be complicating the general question, and the mass of figures entailed thereby would only serve to confuse those who do not intend to study the question in an exhaustive manner. For this reason, although I have the figures before me, I do not propose to attempt it.

Another complication of the question lies in the fact that the line between skilled and unskilled labour is so incoherently and unfairly drawn at the present day, that classification is difficult; for, on the one hand, while many of the so-called labourers who work in conjunction with fitters and boiler-makers, attain to a certain special skill which fits them for their own class of work, so, on the other, many of the machine hands who are habitually classed as skilled are really nothing more than glorified labourers. Then some of the skilled unions in the trade do not, at the present day, hesitate to enrol unskilled hands and even apprentices among their members, as long as they can get subscriptions from them, and such men, by the mere fact of joining, become skilled to all intents and purposes, as far as statistics are concerned. Again, with regard to some of the trades, the men employed in them work under such widely different conditions, and with so great a disparity in the way of skill, that their wages, if given, would be more misleading than otherwise. For instance, smiths doing a certain very high class of work obtain wages amounting to three or four times as much as that paid to other men described under the same heading, while turners on special and complicated work are often paid wages which would in a schedule appear entirely out of proportion to that of others in the same line.

For the purpose of explaining in a simple manner how slightly the size of a town or trade union influence really affect the wages question, I give two schedules below. Both these schedules deal with thirteen localities, all of which may be said to be important engineering centres, with the exception perhaps of Dundee, which is merely put in for the purpose of showing the minimum of wages. That town claims the distinction of paying its men at the lowest rate in the kingdom, some of the fitters in that district receiving about the same wages as first-class fitters' labourers in London.

The first schedule is drawn up in a form which shows at a glance the relative positions of the various districts with regard (1) to their size—from the point of view of population; (2) their rates of wages; and (3) the trade union influence to which they are subjected.

The population column requires no explanation, being merely taken from the ordinary statistics. The rates of wages are gathered from various sources, and are based on the averages paid in the various trades of each district. The trade union influence, as referred to in the schedules, is based on membership rolls issued by the unions, as compared with the total number of men in the locality who might be unionists if they wished to be. Unskilled labour is not taken into account.

It is true that trade unionism is in the habit of bringing to bear all its influence on one or a few localities at certain times, and that its indirect influence on a given locality is not always in direct proportion to its membership, but this I propose to deal with in a forthcoming article.

Table showing the Various Towns in their Order of Size, Wages, and Trade Union Influence.

Population.	Rate of wages.	Trade Union influence.
1 London	London	Belfast
2 Liverpool (with Birkenhead)	Sheffield	Sunderland
3 Glasgow	Manchester	Bolton
4 Manchester	Birmingham	Newcastle-on-Tyne
5 Birmingham	Liverpool (with Birkenhead)	Leeds
6 Leeds	Bolton	Glasgow
7 Sheffield	Belfast	Dundee
8 Belfast	Bradford	Bradford
9 Bradford	Newcastle-on-Tyne	Manchester
10 Newcastle-on-Tyne	Sunderland	Liverpool (with Birkenhead)
11 Dundee	Glasgow	Sheffield
12 Bolton	Leeds	Birmingham
13 Sunderland	Dundee	London

The second schedule deals with the same districts, but gives the actual proportion of the population, wages, and trade union influence to which they are subject, and for purposes of comparison the figure 1000 is taken as representing the maximum in each column, all other figures being proportionate:—

Comparative Table with 1000 as Maximum.

	Population.	Rate of wages.	Trade Union influence.
London	1000	1000	120
Liverpool (with Birkenhead)	112	870	220
Glasgow	103	810	330
Manchester	92	890	250
Birmingham	78	890	180
Leeds	67	790	400
Sheffield	52	950	200
Belfast	46	840	1000
Bradford	39	830	300
Newcastle-on-Tyne	31	830	500
Dundee	27	680	310
Bolton	20	840	900
Sunderland	18	830	950

From the above tables it will be seen that London is the only centre where the wages are in proportion to its size. Whereas, as far as trade union influence is concerned, the five districts where the highest wages are paid are the very five where direct trade union influence is at its lowest ebb. The really union-ridden districts, Belfast, Sunderland, Bolton, Newcastle, Leeds, and Glasgow, rank low as far as wages are concerned, and most of them are among the lowest, viz., 7th, 10th, 6th, 9th, 12th, and 11th respectively.

I rank Belfast as the most union-ridden town of all, because, while during the recent strike there, when the trade societies were boasting that every man in the place belonged to the union, and that every unionist was out on strike, and the total number actually on strike hardly reached 1000, the Amalgamated Society of Engineers alone claim to have over 1800 members on its books in that locality. Again, the general secretary of that union recently stated that Belfast was the strongest union district they possessed. I put London at the bottom of the list in the trade unionist influence column, because out of about 64,000 men in the trade—Booth's "Life and Labour of the People of London," vol. v., is my authority—some 8000 only belong to the Amalgamated Society of Engineers—*vide* their report. Out of these, about one-fifth are compulsory members in Government workshops, and many of the other branches in the metropolis are kept going by large sums sent to them from country branches and from Woolwich, which means that the union very often cannot get its money from the London men.

Of all provincial centres, Sheffield, while being only the seventh town in the schedule as regards population, pays the highest wages. The trade union quoted above has but three branches in this district, and two out of the three are so unsound financially, according to the union's last report, that in order to keep their heads above water they had to receive grants from other localities amounting to over £3 per member for the one year alone. However, there are two other unions in the town, the members of which have to be taken into consideration, otherwise Sheffield would be at the bottom of the list with regard to trade union influence. It is true that the details of the third column of the second schedule may be open to criticism, owing to the untrustworthiness of trade union statistics, and the absence of authorised statistics with regard to the total number of men in the trade in certain of the towns, but no pains have been spared to get at the correct figures, and in a general way they may be looked on as approximately accurate.

Enough, however, has been said to show that in localities where the trade unions are strong it does not follow that wages are higher or even so high as in other localities; and that the size of the town, with the exception of London, is no criterion to the scale of pay. In future articles I shall deal with the various influences which go to produce the great inequality in the rates which at present exists.

THE INSTITUTION OF NAVAL ARCHITECTS.

OUR report last week gave the proceedings for Wednesday; we have only to add that a paper was read in abstract, on "Some Geometry in connection with the Stability of Ships," by Mr. J. Brahn. This was an extremely mathematical paper, and we do not believe that its reproduction in our columns would serve any useful purpose, seeing that our own series of articles are intended to supply all the information our readers are likely to desire on the subject in a very much more simple form. There was no discussion. On Thursday morning papers were read on "Salvage Appliances," by Mr. J. G. Kinghorn, published in our last impression, and on "A Method of Estimating Feed-Water," by Mr. Stromeyer. There was no discussion on either of the papers worth reprinting. A paper by Mr. Seaton on "Microscopical Investigations into Steel," received a good deal of notice. It would be of little service to publish the discussion until we give the paper, and we pass on therefore to the proceedings on Thursday night, when three papers on water-tube boilers were down for reading. The first of these was by Colonel Soliani, on a compound boiler. It is not necessary to give this paper. It will suffice to say that Colonel Soliani proposes to place a number of water tubes in the combustion chamber of a marine boiler. The idea is not new. The Kingstown and Holyhead mail boats had at one time double-ended boilers, and the combustion chambers which were common to both sets of furnaces, and without a dividing wall of fire-brick, were fitted with a couple of vertical tubes of considerable diameter to promote circulation and add to heating surface. Colonel Soliani would, however, use a number of small tubes, with the object of protecting the tube plate. It was pointed out in the discussion, however, that there were considerable difficulties in the way of adopting the plan, one being the interference with the ends of the ordinary fire tubes. It was held generally by those who took part in the discussion that the proposed boiler would have all the faults of both the Scotch and the water-tube boiler, and few of the advantages of either. Colonel Soliani was followed by Mr. Watt, whose paper appeared in our last impression, and he was followed by Professor W. H. Watkinson, of Glasgow University, whose paper we give in full elsewhere.

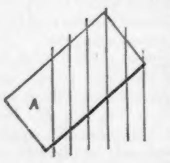
The interest of the meeting centred on this paper, and the hall was crowded to overflowing. Professor Watkinson, however, commenced by saying that instead of reading his paper through seriatim, he would use it as the foundation for a kind of lecture, explanatory of a number of models which he showed in action. These models were all of considerable size. Unfortunately the draughts set up in the hall disturbed the gas flames, and several glass tubes were burst. It was noted, however, that no tubes burst in the model of a Yarrow boiler. On the whole, however, the lecturer's demonstrations were quite successful. It may be said here with advantage that Professor Watkinson has made the action in water-tube boilers a special subject of study, observation, and investigation for the last two years or so, and he has no doubt acquired a great deal of information, much of it very interesting, and we call attention to the fact that his explanation of the cause of circulation in water-tube boilers is identical in every respect with that which we have always and consistently put forward. As we have dealt with the question on another page, however, we shall say nothing further about it here. Two or three facts of considerable interest and novelty were stated by Professor Watkinson. For example, he finds that the size of steam bubbles is almost independent of the pressure, that is to say, they are about as big when the pressure is 100 lb. as at atmospheric pressure. This is contrary to received opinions, but seeing that next to nothing is known as to how a bubble is formed, what determines its size, the surface tension of the fluid surrounding it, and so on, we see no theoretical grounds for thinking that Professor Watkinson's observations in practice are erroneous. The statement, again, that in the Belleville boiler there is no circulation whatever in the commonly accepted sense of the word, evoked no contradiction from anyone present, and appears to be borne out by the behaviour of the large model shown at work, in which the bubbles of steam coursed regularly through the tubes, albeit no circulation of water took place.

The discussions were taken on all three papers together, and, as is usual, was not in any sense adequate. The time at the disposal of the meeting was quite too short, and the speakers hurried over what they had to say, and left the greater part of their notes untouched. Mr. Alfred Durston, Chief Engineer of the Navy, began. He held that Mr. Watt's experiments were not generally applicable, and that the results he obtained only applied to the model boiler he used. After a few remarks on Colonel Soliani's paper, he proceeded to deal with Professor Watkinson's statements. It had been argued that the tubes in the Belleville boiler ought to be arranged athwartships, because rolling would interfere with the circulation. In the French steamers of the Messageries Company, however, no trouble had been experienced, and the boilers were all fired athwartships. In one case a vessel had steamed 300,000 miles without any injury to the boilers, and the engineer reported that they were still in good condition. However, as a matter of fact, in the Powerful and Terrible all the boilers except about one-third in the forward boiler-room were fired fore and aft. The water-hammer action which took place when steam was being got up was of very small importance. As regards the temperature of the tubes, he had had experiments carried out to test the expansion, and thence deduce the temperature of a tube in the middle of a nest in an ordinary marine boiler and of a stay rod beside it in the water, and the experiment was tried in H.M.S. Vulcan. They were ·7in. apart. The tube was found to be 180 deg. Fah. hotter than the water. Similar experiments made with a Belleville boiler showed that the tubes were from 60 deg. to 210 deg. hotter than the water; as to straight and bent tubes, he found that in use all tubes if straight at first bent and became distorted. He preferred the bent tube, as it was less likely to come to grief if the boiler got a little short of water. In certain small Government craft, which he might almost call river police boats for foreign service, he used water-tube boilers with large tubes, because they ought to last about nine years, whereas boilers with tubes of small diameter only lasted three to five years.

Mr. Yarrow stated that he had proposed to give some information as to the methods of making his boiler, but he found that he would be out of order, and so would content himself with saying that his experience with the straight tube had been most satisfactory, and he had had ample experience, inasmuch as about 200,000 tubes are now at work in his boilers. He had recently invented a method of expanding tubes by steam, and he concluded with a graceful invitation to the members of the Institution, particularly the foreign members, to go to the Isle of Dogs to his works, where they should be shown everything.

M. Normand said that in dealing with experiments it was most important to consider their scale. In small model boilers the "steam loop" might exist. There was no doubt a very great difference between the temperature of the tubes and the water, and copper was not a suitable material. The only trustworthy material was steel or the best soft ingot iron. He found by experiment that submerging the upper end of the tubes did not reduce the circulation. Mr. Thornycroft criticised Colonel Soliani's boiler very briefly, and said that Mr. Watt's model proved too much. He then spoke at some length concerning the action of downcomers, but he added very little, if anything, to what is already well known on the subject. Mr. Durston's remarks about tubes were very interesting. He might be pardoned if he said that he preferred the bent to the straight tube. It was most important that the water in a boiler should move in an orderly manner down one set of tubes and up another set. It was most objectionable to have the water unable to make up its mind which tube it would ascend and which tube descend.

After a few words from Captain Sankey and a caution from Mr. Leslie Robinson as to the difference in the value of heating surfaces in different places in a boiler, Mr. Thom went on to describe some experiments he had carried out with a Niclausse boiler in a 47ft. steam launch. The boiler worked very well, and gave no trouble. He thought he would try what effect the internal circulating tubes had, and to this end he ran the boat on a measured course first with the internal tubes, then these were removed, and he ran again, and found to his surprise that the boiler worked just as well without them as with them. As to the use or non-use of downcomers, he pointed out that if we have a U tube heated highly and use one leg of it as a hot downcomer, we may get the other leg crowded with steam; but that if we couple a cool downcomer on at the bottom of the U tube, that we can have two delivering mouths instead of one, and much greater efficiency and less chance of priming.



Mr. Blechynden said that Mr. Watts' results were quite fallacious, because when the tubes in his model were inclined, as the heat of the lamp went straight up the length of tube to be heated was reduced. Thus A is the boiler, and the vertical lines show the hot products of combustion rising. As to metals, copper is a worse conductor than iron while clean; and when dirty, copper and iron give precisely the same result, as will be found by trying the experiment with two ordinary domestic kettles, one of copper the other of iron.

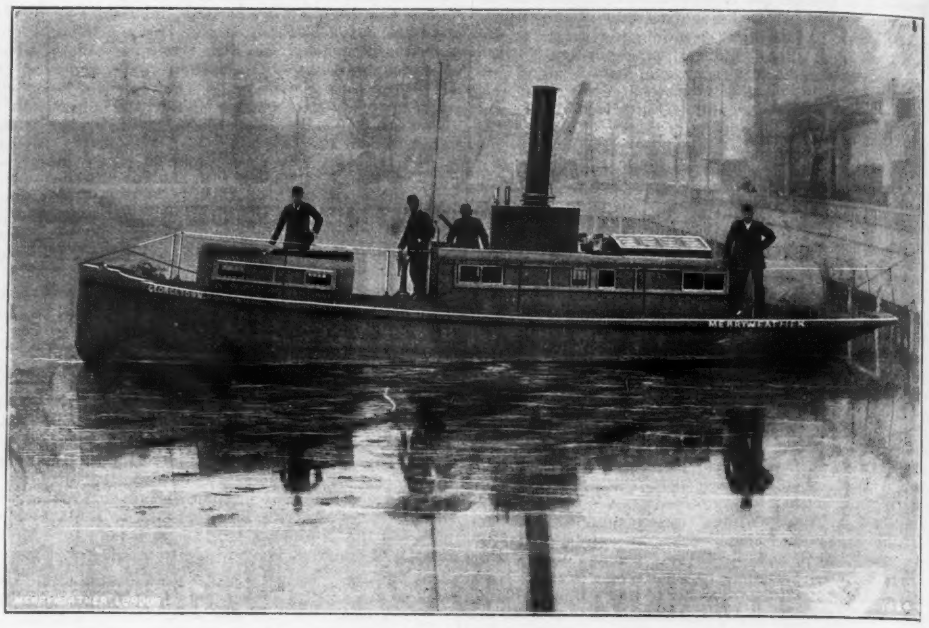
Professor Lambert criticised Professor Watkinson's theory of circulation, and maintained that circulation was caused by difference of density in the water in the two legs of a U tube. If a hot downcomer were used, he thought there was danger that the rising tube would make steam so fast that not enough water would remain in it to prevent overheating. Mr. Wingfield, of Messrs. Thornycroft, held with Professor Lambert that circulation was due to difference of weight in the two legs of the tubes. Copper, according to a somewhat new theory, was spoilt in the brazing, not because it was "burned" or got too much oxygen, but because it was deoxidised.

As the hour was late, Lord Hopetoun closed the discussion, brief replies by Col. Soliani, Mr. Watts, and Professor Watkinson bringing the proceedings to an end. As most of the members rose to go as soon as Mr. Wingfield sat down, it was not easy to catch the somewhat hurried remarks of the last speakers.

On Friday morning the papers read were of extremely small general interest. The first was "The Non-uniform Rolling of Ships," by Mr. R. E. Froude, F.R.S., Associate Member of the Council. The second was on "A New Theory of the Pitching Motion of Ships on Waves, and of the Stresses produced by this Motion," by Captain A. Kriloff, Professor at the Naval Academy of St. Petersburg. A third paper of more general application was "Notes on the Carriage of Grain Cargoes," by Mr. George Herbert Little, which concluded the meeting.

A NEW FLOATING STEAM FIRE-ENGINE

MESSRS. MERRYWEATHER AND SONS, GREENWICH, ENGINEERS



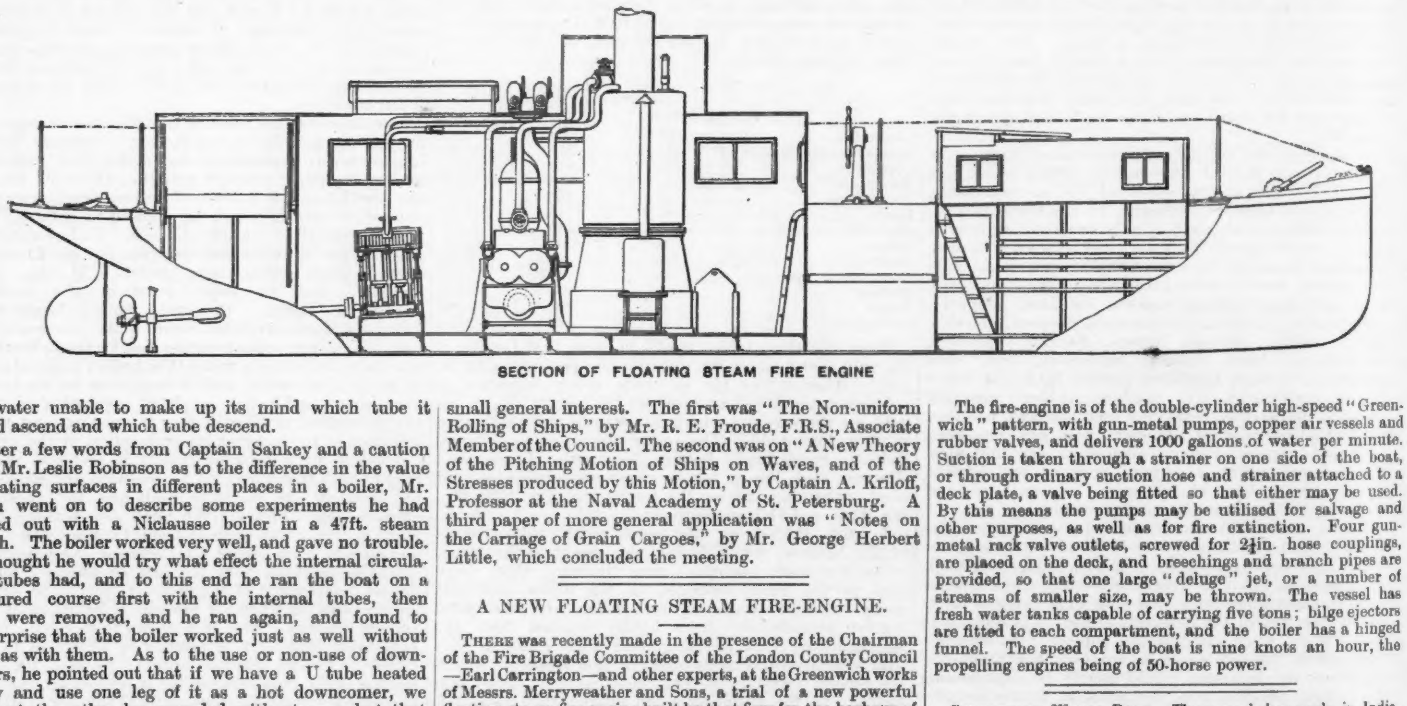
A NEW FLOATING STEAM FIRE-ENGINE.

There was recently made in the presence of the Chairman of the Fire Brigade Committee of the London County Council—Earl Carrington—and other experts, at the Greenwich works of Messrs. Merryweather and Sons, a trial of a new powerful floating steam fire-engine built by that firm for the harbour of Georgetown, Demerara. Supt. E. F. Wright, of the Georgetown Fire Brigade, directed the testing of the apparatus, and the results were very successful. Steam was raised in ten minutes from the time of lighting the fire. A 1¾in. jet of water was thrown with ease 200ft. high, while good results were attained with two 1¼in. jets, three 1in. jets, and as many as eight smaller jets, thrown simultaneously. Having when afloat an unlimited supply of water, the boat can thus attack a fire on shore or amongst shipping from all sides at once. For raising sunken vessels by pumping them out, or for rapidly filling ships' water tanks, this fire float will also form a useful acquisition to the harbour of Georgetown.

The boat, of which we give a sectional elevation in Fig. 2, and an outside view in Fig. 1, is 40ft. long, 10ft. beam, and draws 2ft. 6in. of water aft. It is built of Siemens-Martin steel, and has water-tight compartments fore and aft. There is a cabin forward, with sleeping berths for the crew, a large engine and boiler-room amidships, and a well aft with water-tight doors, containing an iron hose-reel capable of carrying 3000ft. of 3½in. canvas hose. The machinery space is covered with an iron housing, and is fitted with sky and side lights, a hatchway, and ladder. The steering wheel is placed forward of the engine-room, as will be seen on inspection of the engraving below, and a windlass, mooring bitts, anchor, &c., are provided.

The boat-propelling machinery consists of a pair of double-cylinder engines of the inverted vertical type, driving twin screws. The engines have double link motion reversing gear, and enable the vessel to be easily turned, the swift current of the Demerara River rendering this arrangement necessary.

The boiler is of Merryweather's patent vertical water-tube type, capable of raising steam from cold water to 120 lb. pressure per square inch in about ten minutes from the time of lighting the fire. In actual working this time will be considerably reduced, as a novel petroleum-fired feed-heater is carried, which will enable the water in the boiler to be kept constantly above boiling point. The boiler tubes are of copper, and the shell of steel. The boiler feeding arrangements are very complete, including two feed pumps on the fire-engine, a self-starting injector, and a separate donkey pump.



SECTION OF FLOATING STEAM FIRE ENGINE

The fire-engine is of the double-cylinder high-speed "Greenwich" pattern, with gun-metal pumps, copper air vessels and rubber valves, and delivers 1000 gallons of water per minute. Suction is taken through a strainer on one side of the boat, or through ordinary suction hose and strainer attached to a deck plate, a valve being fitted so that either may be used. By this means the pumps may be utilised for salvage and other purposes, as well as for fire extinction. Four gun-metal rack valve outlets, screwed for 2½in. hose couplings, are placed on the deck, and breechings and branch pipes are provided, so that one large "deluge" jet, or a number of streams of smaller size, may be thrown. The vessel has fresh water tanks capable of carrying five tons; bilge ejectors are fitted to each compartment, and the boiler has a hinged funnel. The speed of the boat is nine knots an hour, the propelling engines being of 50-horse power.

Corrugated Water Pipes.—These are being made in India. Corrugated iron culverts from 12in. diameter to over 24in. in diameter have been largely used there for some time, and an Indian paper says there is a great demand for corrugated iron culverts of a smaller diameter, but it has been hitherto almost impossible to make them so small as 18in. diameter, owing to the great difficulty in bending the sheets without injuring the material. Spirally corrugated culverts can, it is said, be made any diameter without cracking or damaging the material. Considering the small delivery through frictional and eddy losses which such pipes would have, it is curious that the form should have acquired any favour.

The Civil and Mechanical Engineers' Society. — At the meeting held on Thursday, March 26th, Mr. A. Myall, A.M.I.C.E. read a paper on "Wire Netting Machinery." The author reviewed the history of his subject, drawing special attention to the patent of 1854 of J. Whitehead, in which was embodied the essential principle upon which the majority of subsequent machines have been constructed for manufacturing wire netting. He entered into the details of many machines, and pointed out their main features and the reasons for their adoption or rejection, and concluded his observations by drawing attention to the various defects of the machines at present in use; and indicated where, notwithstanding all that had been done and the thousands of miles of wire netting that had been made, there was still plenty of room for improvement in the machines now in operation. A discussion ensued, and the following gentlemen took part therein:—C. T. Walrond, Hal Williams, E. H. G. Brewster, J. N. Cooper W. Cooper Penn, and Chester Dawson.

THE SAFETY OF COMPRESSED GAS CYLINDERS.

In May of last year a Committee of Inquiry was appointed to consider the causes of explosion of cylinders containing compressed gases, and the measures which might be taken to increase the safety of such vessels. With Professor Unwin as chairman, and with an adequate array of experts, including a distinguished chemist in the person of Dr. Dupré, as members, the Committee may be considered representative and likely to be efficient. The report of the deliberations of this body, which has lately been issued, bears out this supposition. It is clear, judicial, and tolerably exhaustive. The conclusions are reasonable, if not incontrovertible, and with certain of the recommendations all interested in the subject will agree. A detailed account of the evidence, or even of the report based thereon, would be out of place here. The whole document is procurable for a trifling sum, and will be doubtless in the hands of all technically or commercially concerned in the manufacture and testing of the cylinders and their contents; such will find it excellent reading. A few of the more important matters touched upon may be briefly dealt with.

In a disclaimer as to the jurisdiction of the Committee over cylinders used for military purposes which appears in the preamble, occurs a statement not to be let slip. It is said with truth that compressed gas cylinders used in our own and continental armies are of lighter construction than those employed in ordinary trade. It would be distinctly interesting to know by the use of what material or of what methods of manufacture such cylinders are prepared so as to cause no excessive risk of accident, and yet to fulfil the onerous conditions of weight necessitated by the requirements of military service. It would then be possible to judge whether the use of similar material and methods might be adapted to commercial requirements, or whether there are in military cylinders inherent causes of danger which would make their employment, even in a modified form, wholly inapplicable to civil purposes.

Weighty words, which will be found wholesome if bitter by the scaremongers who clamoured for drastic legislative action on the strength of a few explosions attended by loss of life, are embodied in the section of the report dealing with the advisability of recommending some control of the trade in compressed gas cylinders. It is said with much cogency that "the risk in the generation of steam is probably greater"—than that in the use of cylinders of compressed gases—"and yet, in this country, it has not been found desirable to interfere with the responsibility of steam users by official regulations." The report goes on to point out that accidents to cylinders of compressed gas are more likely to occur in public and crowded places than are those which occasionally determine the existence of boilers, and in succeeding paragraphs leans to the exercise of a certain amount of control. The discussion of this question may be left until the conclusions and recommendations of the Committee are considered in a later part of this article, but the broad fact remains that, having regard to the magnitude of the present trade in compressed gases, the number and gravity of the explosions which have occurred are altogether insignificant.

The possible causes of explosion fall under three heads. The first is the ignition of an explosive mixture in the cylinder. Mixed hydrogen—or coal gas—and oxygen, constitute an explosive of a formidable kind if their proportions fall within well-known limits; no cylinder extant can be expected to withstand the bursting action of such a charge should it by chance be fired. Seeing that cylinders of mixed gases are not an article of commerce, the occurrence of a mixture in a cylinder is generally due to carelessness, and is most readily avoided by the use of fittings with left-hand threads for the less common, *i.e.*, the hydrogen cylinders. The spontaneous ignition of mixed gases in a cylinder is possible, but rare, and its causes have not been satisfactorily elucidated. With the precaution indicated above, viz., the employment of non-interchangeable fittings, this risk of explosion becomes infinitesimal. The second cause of explosion is the mechanical weakness of the cylinder. This weakness may arise from undue thinness—general or local—of the walls of the cylinder, unsuspected flaws—as in a badly closed weld—and from defect in the quality of the metal of which the cylinder is made. With regard to this last, the metal may be softer and of lower yielding point than a material should be to carry the working pressure; cases of failure from this cause are, however, but little likely to happen if the cylinder has been subjected to an hydraulic test considerably above the working pressure. Conversely, the metal may be unduly hard and brittle, either from faulty composition—of which more anon—or from bad annealing after manufacture. The third possible cause of explosion is the exposure of a sound cylinder containing a liquefied gas to excessive pressure generated by accidental heating; adequate spare space in the cylinder ensures that the liquefied gas shall only exert upon the cylinder the pressure of its saturated vapour at the temperature prevailing, but should the cylinder be nearly or quite full of liquefied gas at the temperature of filling, and be afterwards exposed to a higher temperature, the pressure exerted by the expansion of the liquid *qua* liquid may be destructive in its effects. A knowledge of the capacity of the cylinder and of the weight of liquid placed therein evidently suffices to prevent accidents from this source. The chief possible causes of failure of cylinders of compressed gas having thus been sketched, it is clear that, given the most ordinary care and skill in manufacture of the cylinders and of their contents, no serious risk is to be apprehended from any cause other than some defect in the quality of the metal of which the cylinders are constructed. Wrought iron may be dismissed as being used in small and decreasing quantity, and attention may be concentrated on ingot iron—"mild steel"—as the most usual material for making cylinders. The chemical composition of the ingot iron used is of primary importance, and much controversy has arisen concerning what, if any, limits may be fairly laid down. It is generally recognised that the quality of ingot iron is governed by the nature and amount of the impurities which it contains; speaking broadly, of these carbon, and in smaller degree manganese, are legitimate hardening and strengthening constituents, while silicon, sulphur and phosphorus are most esteemed when absent.

It is, therefore, surprising that in the rules for the transport of cylinders which the railway companies endeavour to enforce, the percentage of carbon alone is specified, 0·2 per cent. being adopted as the maximum, while no direct restriction is placed on the proportion of other constituents. Such a regulation is best passed over in charitable silence. Returning to the region of right reason, it may be said that high class ingot iron, containing little but Fe and C, is likely to prove a safer material even when its content of carbon appreciably exceeds the limit suggested above, than a metal containing as much and as many impurities as an indifferent steel maker may venture to leave in, "corrected" by a copious dose of manganese. Should it prove requisite to fix limits of composition, systematic experiments on cylinders of metal, the analysis of which is accurately known, will be requisite. With the data thus collected it may be possible to construct a sliding scale for the permissible percentage of carbon, according to the nature and amount of the other elements present.

One section of the report of the Committee treats of the danger which may arise from the explosion of pressure gauges—which is sometimes traceable to the presence of oil in the Bourdon tube. The whole matter was threshed out some years ago, and as the Committee remarks, such care is now taken by makers that no accidents have lately occurred. A question of greater novelty and interest is the protection of cylinders from corrosion, and consequent weakening. At present it appears that no precautions against internal rusting are in use. Seeing that, owing to the necessity for subjecting the cylinders to an hydraulic test, water is left adhering to the inside of the cylinder, the probability of internal corrosion proceeding unperceived is not trifling. Some limit to this injurious effect is set by the fact that carbon dioxide, which is a potent if not indispensable adjunct to water and oxygen as rusting agents, is usually absent from oxygen made by modern processes, and thus a wet cylinder filled with compressed oxygen would not necessarily suffer severe corrosion. It is not advisable, however, to rely on a fortuitous safeguard which may disappear with an alteration of manufacturing methods, and some protective coating for the interior of cylinders — duly chosen with regard to what they are intended to contain —should be devised and adopted. In the summary of recommendations made by the Committee, appearing at the end of the report, the following points may be touched on. Cylinders made of ingot iron for oxygen, hydrogen and coal gas should consist of metal containing not more than 0·25 per cent. of carbon—0·05 per cent. higher than that desired by the railway companies—and not less than 99 per cent. of pure iron. The greatest working pressure should be 120 atmospheres, and the stress due to working pressure should not exceed 8 tons per square inch for seamless cylinders, and 7½ tons per square inch for lap-welded cylinders. The tensile strength of the metal should be between 26 tons and 33 tons per square inch, and the extension should be not less than 1·2in. in 8in. An hydraulic test of the cylinder of 224 atmospheres should be adopted, and the permanent stretch of the cylinder thus tested should not exceed 10 per cent. of the elastic stretch. It is recommended that cylinders complying with these conditions should be allowed to be sent by road or rail without packing. It is further recommended that "there should be a general inspection of all factories manufacturing compressed or liquefied gases under the direction of the Factory Department of the Home-office, or, possibly, a department of the Board of Trade," and that the inspectors thus brought into official existence should be entrusted with considerable powers.

It will be seen that certain of these recommendations, if ultimately adopted, will have wide-reaching effects. The maker will be tied down to a particular quality of steel—not necessarily the best—and to a particular minimum thickness of the cylinder walls, and will be liable to the supervision of a Government official at all stages of his work. The prospect is scarcely alluring to a manufacturer accustomed to carry out his own processes in his own way; and it will hardly be surprising if opposition be offered to the translation of the recommendations of the Committee into statute form. We are disposed to consider that the Committee has taken too fearful a view of dangers that may never come. That the risk which is sought to be averted is somewhat remote appears from a phrase in the report. After alluding to the few accidents which have hitherto occurred, largely because of manufacturers' voluntary precautions, the Committee goes on to say that there is "a possibility that, in the course of time, with increase of competition in the trade, the care and attention on which safety has depended may be sensibly relaxed." So moderate and sensible a forecast as this scarcely warrants the recommendation of drastic restrictive measures for meeting a doubtful contingency. That the Committee has acted in good faith, and is free from the influence of mere panic, none who study its composition can doubt for a moment. It is, therefore, reasonable to suppose that the recommendations are to be taken as a warning rather than as a draft scheme for legislation. Having regard to the fact that official interference is now tolerated with edifying meekness by all classes and interests, manufacturers cannot usefully attempt to repudiate supervision in any other way than by showing that they already exercise as much care and skill in a somewhat difficult industry as can fairly be demanded of them. Failing this, and given another explosion or two, they will find themselves securely swathed in highly inelastic ligatures, fiery in hue and official in design.

H.M.S. MARS.

From the *Globe* of the 25th April, 1894, we observe that the name was won from the French just one hundred and fifty years ago, in one of the smartest single-ship actions ever fought. The taking of the Mars by the gallant Captain "Phil" Saumarez, of the Nottingham, off Cape Clear, was the talk of the year 1746. Our captured Mars—a sixty-four —did nine years' service under the British flag, and then was wrecked when with the first expedition against Louisburg. The second Mars—a seventy-four—launched within two years of her predecessor's loss, saw service at Quiberon Bay in Hawke's heroic victory on "la journée de Monsieur Conflans" in November of "the wonderful year." After serving on the active list for some thirty years, she eventually became a hospital ship at Portsmouth. Our third Mars—another seventy-four—was launched in 1794. In the first year of her career, the Mars won high distinction for the gallant part she took as rear ship in Cornwallis' brilliant fighting retreat before the French Brest fleet—five British line-of-battle ships and two frigates against twelve French line-of-battle ships and thirteen frigates. Three years later—in 1798—the Mars chased, brought to action, and took single-handed, well within sight of Brest Roads and the French fleet there, the French seventy-four Hercule, after one of the most desperately contested single-ship duels on record. The Mars lost her gallant commander, Captain Alexander Hood, in the battle, as well as sixty men. At Trafalgar the Mars was the third ship of Collingwood's line to get into action, and she acquitted herself with distinguished gallantry throughout the battle. Her commander, Captain George Duff, was killed by a cannon shot on his own quarter-deck. From 1805 to 1813 the Mars was constantly on war service in the Channel, in the Bay of Biscay, and in the Baltic, including the bombardment of Copenhagen in 1807. She was broken up in 1816. The fourth Mars, an eighty-one gun ship—now training ship to a local association at Dundee—was built at Chatham in 1843. The new Mars is the fifth of her line.

The Mars, built by Messrs. Laird Brothers, of Birkenhead, is one of the largest battleships constructed for the British Navy. She is of the Majestic type or class, and was designed by Sir William H. White, K.C.B., Director of Naval Construction. Her dimensions are:—Length, 390ft.; breadth, 75ft.; mean draught, 27ft. 6in.; displacement, 14,900 tons; freeboard, forward, 25ft.; aft, 18ft. 6in.; power of engines, with forced draught, 12,000 indicated horse-power; with natural draught, 10,000; speed, natural draught, 16½ knots; forced draught, 17½ knots; coal, carried at the designed load draught, 900 tons, with a reserve of 500 tons a side, making a total stowage for 1900 tons, with which she will steam at 10 knots for about a month, or 8000 knots. The reserve bunkers form additional protection, with an armoured deck behind side armour. The barbette guns are above the water-line 27ft. The citadel or side armour is 220ft. long, with a vertical height of 15ft. of Harveyed steel, 9in. thick, and barbette's 14in. thick. The protective deck from the lower edge of the armour, covering machinery, magazines, and other vital parts, is 4in. thick on the slopes and 2½in. thick on the flat, and extends to the extreme ends.

The ship is exceptionally strong, and built entirely of mild steel, the stem and stern post, rudder and shaft brackets being formed of steel castings. There is a double bottom, and numerous subdivisions by athwartship and longitudinal bulkheads to minimise to the fullest possible extent the danger arising from damage to the outer plating. These bulkheads are so arranged as to form passages for easy communication below the water-line from end to end. In order to procure a safe passage for the ammunition from the several magazines to the guns of the secondary armament, armoured tubes have been specially fitted. It is also to be noted that, with a view to preventing water from finding its way below the protective deck, means are provided for closing the several openings by water-tight covers, while in the case of those which must necessarily remain open, coffer-dams have been fitted with the same object. She is lighted throughout with an installation of about 900 electric lights, and equipped with six search-lights of 30,000-candle power, each of which is capable of being worked by dynamos under protection. There are two conning towers, the forward tower armoured with 14in. and the after one 3in., and to these towers are led all voice pipes and telegraphs to be used by the officers in charge of navigating the ship when in action. The port and starboard engines and boilers are separated by middle-line longitudinal bulkheads, and, therefore, can be worked independently. There are also longitudinal bulkheads, also water-tight, at the sides, extending throughout the machinery space, forming coal bunkers and wing spaces. On the platform *débris* and lower decks is placed the auxiliary machinery for the working of the ship, including steering engines in duplicate, electric engines—the electric wiring being done by Messrs. Laird—and hydraulic pumping engines, as well as a fully-equipped engineers' workshop, and numerous store-rooms. The officers and crew are accommodated on the main and belt decks. The officers' accommodation consists of very completely fitted cabins situated aft, the superior officers being located on the main deck. The Admiral's suite of rooms, which are especially handsomely fitted, are at the extreme aft end of the main deck, and communicate with a handsome stern walk. The upper deck extends from stem to stern without a break, and above it is a continuous bridge deck, extending the whole length between the barbettes, and on this deck are the conning towers, surmounted by the navigating bridge, which will be about 40ft. above water, and the chart-house.

The boats, of which there are eighteen, including two torpedo boats, are stowed amidships. A strong steel derrick is fitted to the mainmast for lifting them, and wood derricks are also fitted in the side of the casings for working those of a lighter description. The masts, which are built of steel, are fitted with military and signalling tops, and there are two funnels on the same athwartship lines.

The armament of the Mars will comprise four 12in. 46-ton breech-loading, new type, wire-coiled guns, mounted *en barbette* in pairs, and firing a projectile weighing 850 lb., with a powder charge of 148 lb. There are fifty quick-firing guns in all—twelve 6in. on the main and upper decks, mounted in casemates protected by 6in. armour, eighteen 12-pounder, twelve 3-pounder quick-firers, eight small machine guns, and five field guns. The auxiliary armament of the lighter guns is distributed all over the ship, a considerable number disposed upon the bridge and in the mast tops. The main armament is worked by hydraulic machinery, supplied by Sir W. G. Armstrong and Co. The other guns are all worked by hand. There are five torpedo tubes, four submerged, while one discharges above water at the after end.

The main propelling machinery consists of two sets of engines of the triple expansion inverted type of Messrs.

Laird Brothers' most advanced design. Each set is placed in a separate engine-room. The cylinders are—high-pressure 40in., intermediate-pressure 59in., and low-pressure 88in. in diameter respectively, with a stroke of 51in., and are separate castings bolted together by brackets. The slide valves for the high-pressure are of the piston type, for the intermediate and low-pressure cylinders flat double-ported valves. The main condensers, which are of brass, have a collective cooling surface of 13,500 square feet, and there are four centrifugal pumps, each driven by an independent engine. The shafts and all the principal moving parts are of steel, as usual. The screw propellers are four-bladed, the blades and bosses being of manganese bronze. The boilers are eight in number, single-ended, of the cylindrical return tube type. Following out the search for safety on the principle of subdivision, each pair of boilers is in a separate water-tight compartment, with independent coal supply, separate access to and from main deck, &c. The exhaust steam from the whole of the auxiliary machinery in the ship is delivered to an exhaust pipe connecting with the two auxiliary condensers, one in either engine-room, each of these condensers having its own air and circulating pump worked by an independent engine.

Two distillers with circulating and distributing pumps, four Admiralty type main feed and four auxiliary feed pumps, of ample size to supply the whole of the boilers at full power, and four double-cylinder double-acting bilge and fire-pumps, and a pump for pumping out the drain tank, are provided. The several pumps are connected to the large drain pipe and double bottom. General ventilation is secured by two large fans 72in. in diameter; and eight fans 72in. in diameter supply the forced draught for the boilers and engines. The weight of the anchors and chain cables is 112 tons, and if the cables were laid out in a single line they would extend about one mile. The total weight of metal work treated in the construction is upwards of 10,000 tons, and the wages expenditure in Birkenhead alone was upwards of a quarter of a million.

The Mars illustrates the advantage of building these large battleships in dock in preference to building them on a slip and launching them, as she carries with her all her citadel armour and most of the barbette armour and four casemate fronts; indeed, all the armour-plating would have been completed had it not been for the press of work in Sheffield rendering it impossible for the armour-plate manufacturers to make delivery as early as required. The main boilers are on board, with all mountings and connections complete ready for steam save the funnels. The whole of the auxiliary machinery is also in place, and pipes and connections fitted, and the main engines are fully two-thirds erected on board, so that the vessel as floated out from the building dock is in a far more advanced state than would have been the case had she been launched in the ordinary way.

The order for the Mars was given exactly two years ago on the 26th March, and steel and other material got, and her keel was laid on the 2nd June, 1894, practically twenty-two months to date, and when ready for the pennant in six or eight months she will have a complement of 750 men.

The service appointed to be used at the launching of ships of her Majesty's Navy was read by the Rev. Canon Linton, M.A., Vicar of St. Mary's, Birkenhead, and the vessel was named by Mrs. Laird, wife of the senior member of the builders' firm. A large concourse of spectators witnessed the proceedings, and among the guests were many distinguished individuals.

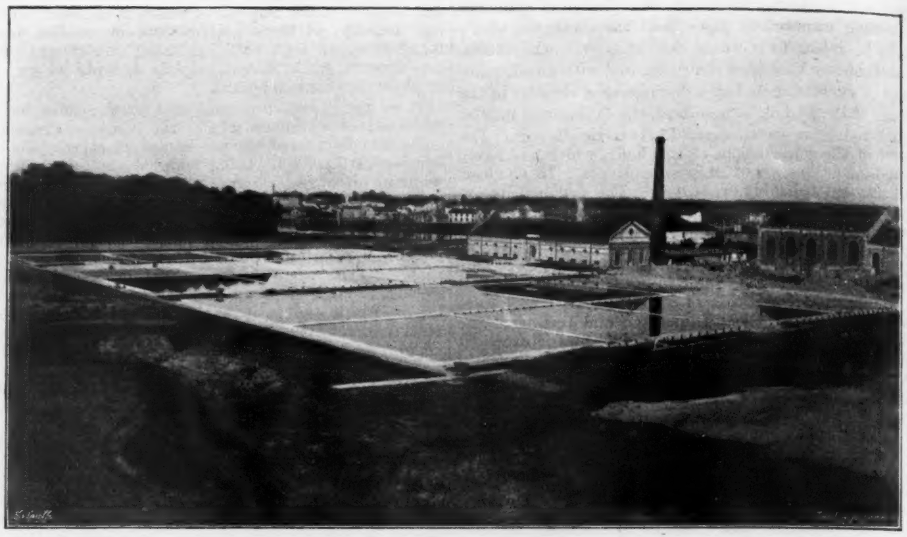
THE PROPOSED CRINAN SHIP CANAL.

As briefly intimated in our issue for the 6th ult., a proposal has been under the consideration of shipping and commercial circles in Glasgow and the West of Scotland for some years past to form a canal extending from Loch Gilp to Loch Crinan. The direct object of this, of course, is to cut off the 85 miles or so of impediment interposed by the long peninsula of Kintyre between the commerce of the Clyde and the West and North Highlands, and the Baltic and North German ports. The proposal is now assuming a more practical shape, and influential shippers and commercial gentlemen in Glasgow and the West Highlands are interesting themselves in promoting a definite scheme. Messrs. Crouch and Hogg, Glasgow, have prepared plans, and opinions have been taken and calculations made which show that the proposal is not only practicable, but that such a canal would prove of immense benefit, and in all likelihood an undertaking which would be immediately successful financially. It is anticipated that in addition to the smaller vessels which use the present Crinan Canal, most of the West Highland steamers yachts of all sizes, and vessels trading between Glasgow and the north-west of Europe would take advantage of the waterway as being the shortest and safest. The present Crinan Canal, constructed about the end of last century, is, of course, inadequate to the requirements of modern shipping, being narrow and shallow, and having a large number of locks throughout its length of nine miles, all of which are of the small size common at the time of construction.

According to the plans which have been prepared the canal will be 20ft. in depth and of 80ft. width on bottom, sufficient to allow vessels of at least 1500 tons to pass through. It will extend from the head of Loch Gilp in as straight a line as possible to Bainakill, from whence it will wind to Old Crinan, its western end, the distance altogether being about six miles. There will only be two locks, one near each end, and the summit level will only be from 6ft. to 8ft. above high-water level. The engineers, in fact, have selected the lowest ground available throughout the entire route, and they believe the work, as a whole, will be very easy of execution. They propose to accomplish the greater part of the work by dredgers cutting their own flotation, and using suction dredgers where the material is suitable. There is only one stiff piece of rock-cutting throughout the whole route, situated between Cairnbrom and Dunardry, the summit of the present canal.

Thence the new ship canal would proceed through Crinan Moss, a tract of waste which Rennie, the engineer, in laying out the present canal, purposely avoided. The engineers of the present scheme boldly propose to carry the ship canal through the moss for a distance of about a mile and a-half. To accomplish this they would form an embankment across the mouth of the river Add, at Crinan, by this means forming a large reservoir on Crinan Moss, the surface level of which would be that of the new canal—6ft. or 8ft. This would obviate the need for any artificial banks at this part of the route, the canal simply being a dredged channel defined by buoys. The estimated cost of the whole scheme, which also includes the reclamation of the extensive ebb at Lochgilphead, is about half a million sterling.

WATERWORKS AT CHOISY-LE-ROI

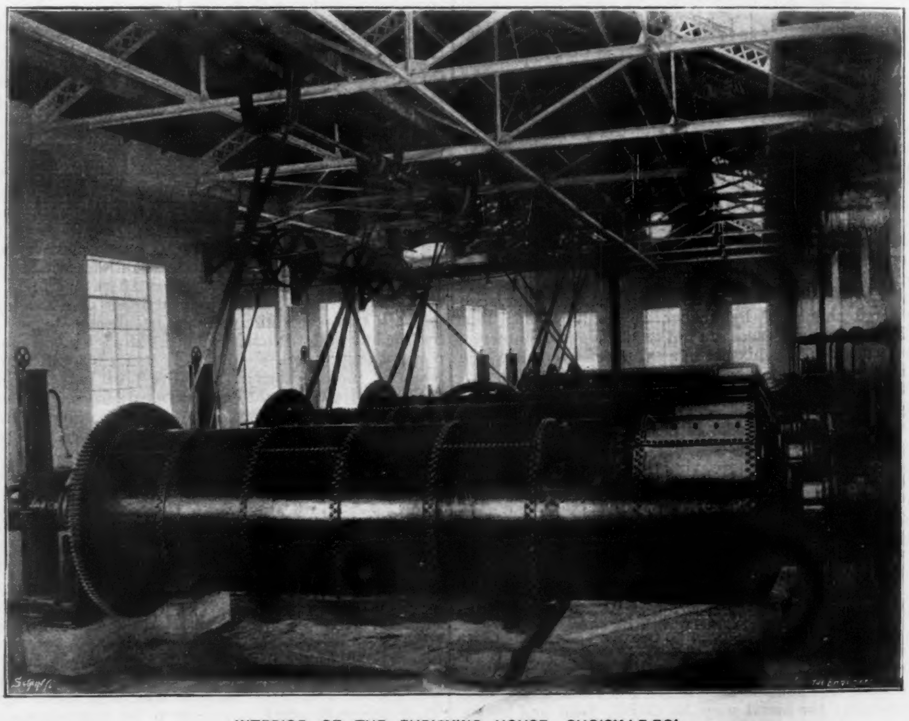


THE WATER SUPPLY OF THE PARIS SUBURBS.

On the 21st of February the Prefect of the Seine, accompanied by a large number of representatives of the various Communes of the Department, visited the waterworks of the Compagnie Générale des Eaux at Choisy-le-Roi, in order to inaugurate the new supply to the suburban Communes of the Department.

By a contract made early in 1894 between the Compagnie Générale des Eaux and the Department of the Seine, the Compagnie des Eaux undertook to erect at various pumping stations complete plants for purifying the waters of the rivers Marne and Seine, capable of dealing with 70,000 cubic metres of water daily, or over 15 million gallons. These plants were to be in complete going order by January 1st, 1896.

The method of purification adopted is the now well-known "Anderson" process, in which the water is agitated with scrap iron, in horizontal revolving cylinders, and afterwards filtered rapidly through sand. This process was employed by the Compagnie des Eaux at their Boulogne-sur-Seine pumping station four years ago, and by its aid the Seine water taken below the city was converted into a supply which rivalled the spring water of the Vanne in purity. The Compagnie des Eaux has guaranteed that by the employment of this process it will remove 99·6 per cent. of the microbes present in the raw river water at the intakes of the new works.



INTERIOR OF THE PURIFYING HOUSE, CHOISY-LE-ROI

These installations, which were all in operation by the appointed day, are situated at three points: at Choisy-le-Roi, on the Seine, and at Nogent-sur-Marne and Neuilly-sur-Marne. From the three pumping stations extends a network of mains which embraces the city, and supplies the whole of the extra-mural Communes of the Department of the Seine, except a few supplied by another company. The population supplied at present is about 600,000.

The purifying plant at Choisy-le-Roi pumping station comprises six revolving purifiers with 14in. inlet pipes, delivering into a settling channel of special design, and fifteen filters each of 625 square metres area, or in the aggregate 100,000 square feet. The daily capacity is 30,000 cubic metres, or nearly 6½ million gallons. The works at Neuilly-sur-Marne are a duplicate of this, dealing with the same quantity, and at Nogent-sur-Marne are three 14in. machines with corresponding filters treating 10,000 cubic metres, or 2¼ million gallons daily.

The results are already excellent, and fulfil the guarantees of the Compagnie des Eaux. In his speech at the inauguration the Prefect of the Seine drew special attention to the clearness and limpidity of the water, being able to read letters on the wall of a house at a distance through a thickness of five metres of the water.

Our illustrations comprise a general view of the works at Choisy-le-Roi, showing engine house, purifier house, settling arrangement and filters, and a view of the interior of the purifier house, showing the six 14in. revolving purifiers with the overhead shafting for driving them.

With regard to the few Communes alluded to above as not being included in the supply from the pumping stations of the Compagnie des Eaux, it may be stated that they are those occupying the loop of the Seine to the north-west of the city. The concession for supplying water to these Communes is in the hands of the Compagnie des Eaux de la Banlieue, which has concluded with the Department of the Seine a contract precisely similar to that under which the plants just inaugurated have been erected. Its supply will be taken below the city at Suresnes, and purified by Dr. Anderson's process, as it has been proved by the four years, working at Boulogne-sur-Seine that the Seine water taken below the city and treated on this system furnishes a perfectly pure and wholesome supply.

The process is also almost certain to be applied to another important river-derived supply in the same locality.

It may be added that the satisfaction given by the new supply is so great that it has already been decided that in the course of the present year the quantity of purified water pumped from the three works of the Compagnie des Eaux shall be increased from 70,000 cubic metres to 110,000 cubic metres daily, or over 24 million gallons daily.

All trade disputes on the Clyde have now been arranged, and vessels aggregating 300,000 tons are in hand. During March the number of vessels launched was double that of January and February combined. Twenty-nine steamers of fully 40,000 tons aggregate were launched, against nineteen of 20,000 tons. Twenty-two steamers were for British and seven for foreign owners.

THE JAPANESE WARSHIP FUJI.

THE Japanese war vessel launched on Tuesday from the Thames Ironworks and Shipbuilding Company is named the Fuji, or "Unequalled," and the following are a few of the principle features of her design:—

	ft.	in.
Length between perpendiculars	374	0
Breadth..	73	0
Draught of water	26	6
Displacement	12,450 tons	
Coals at this draught	700 tons	
Total capacity	1300 tons	

The original inquiry in 1883, through Admiral Ito, was for an improved Collingwood, but the displacement tonnage was to be limited to 8000 or 8500 tons, and seeing it was difficult to improve on a Collingwood with 1500 tons less weight, the necessity of a larger tonnage soon became evident, and a limit was then given of 10,500 tons, or a Centurion type; but as it was required to carry a heavier armament than that vessel, a still larger tonnage became necessary, resulting in a vessel of 12,450 tons, of the Royal Sovereign type, as above. The Fuji has an armour belt 226ft. long, 18in. thick through machinery and boiler spaces, and 16in. at ends; two barbettes, armour plated with 14in. armour, and standing upon the armour deck. A screen of 6in. armour runs across on the main deck, as well as on the lower deck to protect the broadside 6in. quick-firing guns from a raking fire; also a belt of 4in. armour on 2in. teak backing between main and lower decks of about the same length as the main belt.

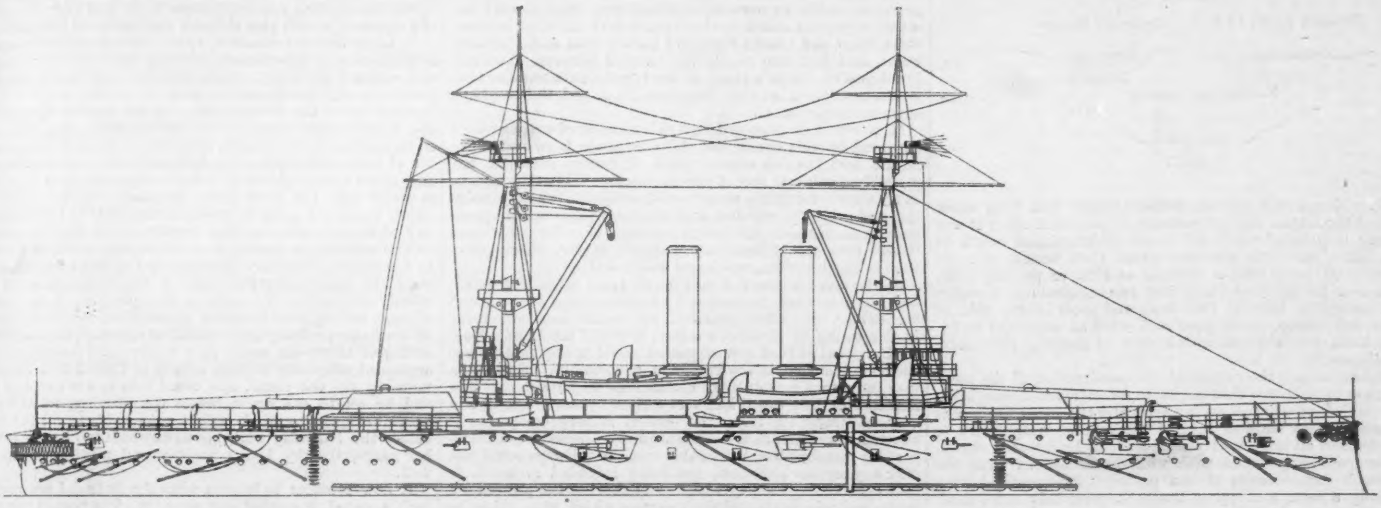
The barbettes carry two 12in. breech-loading guns in each, with armoured shields 6in. thick, also ten 6in. quick-firing guns, four of which are in casemates and the other six on the upper deck, and protected by heavy shields; twenty 3-pounder Hotchkiss quick-firing guns, four 2½-pounder Hotchkiss quick-firing guns, and five 18in. torpedo ejectors, one above water and four below.

The armour deck extending from stem to stern is 2½in. thick, and terminates in a powerful ram at the fore end. The decks are of teak. There are two military masts with double tops, with derricks for lifting the boats in and out from off the skid beams. Thirteen boats in all are to be carried, including two 56ft. vedette boats, navy pattern. Five search lights, and the whole of the vessel to be lighted internally by electricity. The conning tower is 14in. thick, and the director tower aft 3in. thick.

In view of the disastrous effects of the shell fire from the machine guns, as witnessed in the late war with China, all woodwork is substituted by steel and other metal wherever possible. The seamen's mess shelves, and also other fittings, as the bulkheads of the saloons and cabins, are all of steel and brass. The engines, which are triple expansion, of 14,000-horse power, are constructed by Messrs. Humphrys, Tennant, and Co., of Deptford, the boilers being of the usual cylindrical type. Speed, 18¾ knots. The vessel has been designed by Mr. George C. Mackrow, naval architect of the Thames Ironworks and Shipbuilding Company.

Good progress is now being made with her construction, as upon the cessation of hostilities with China it was suggested by the Japanese Government that the time of completion should be shortened, and the past few months have made a very material change in her general appearance on the slip, otherwise the delivery was not required for five or six years, so that twelve months' time has been lost. Some 7300 tons of material are in her, including 1600 tons of Harveyed armour, some of which plates weigh 28 tons, and cost £2870 each. The armour for the hull has been made by Messrs. Vickers and Son, of Sheffield, and the nickel casemate armour by Messrs. William Beardmore and Co.

The construction of the vessel is under the superintendence of Captain Takayama, that of the engines under Captain Miyabara, that of the armament under Lieutenant Kitakoga, while Captain Yendo, who is also Naval Attaché to the Imperial Japanese Embassy, is the chief of the Commission. The Thames Ironworks find, however, that they are entering upon a new experience in fitting out this large vessel and adapting and fitting all the multitudinous departments to the requirements of their clients in the Far East. In Europe methods of feeding and systems of carrying provision for crew and officers are fairly uniform, barrels and cases being of pretty general proportions, but the Japanese provisions are stowed in barrels, conical shape, something like our harness casks, and most inconvenient for stowing, as the larger diameter is at the top, and not at the bottom, as with us, so that each barrel or cask has to have its allotted place, and consequently there is a great loss in stowage.



THE JAPANESE WARSHIP FUJI

ENGINEERING SOCIETY, KING'S COLLEGE, W.C.—At the terminal business meeting of this Society held on Friday last—27th—the following gentlemen were elected officers for the ensuing term:—President, Mr. M. Mowatt; vice-president, Mr. D. J. Strutt; re-elected; hon. treasurer, Mr. R. Robinson; hon secretary, Mr. R. W. Bailey.

DUNOON BURGH PIER.

FOR some time past the existing pier at Dunoon has been found too small for the growing traffic of this favourite Clyde watering-place, whilst the shallowness of the water around it has been a constant source of inconvenience at certain states of the tides to steamers coming alongside. Last year it was decided by the Burgh Commissioners to construct a new and more commodious pier in deeper water, and parliamentary powers were accordingly sought and obtained to effect this. Eventually, as the result of negotiations with the Hafton Trustees, owners of the existing pier, that structure was acquired, *inter alia*, by the Dunoon Burgh Commissioners, for a sum of about £27,000, which included sundry rights and property on shore; and it was decided to incorporate the old pier in the new one, and to utilise the existing gangway for goods and luggage traffic, leaving the new gangway free for passengers. This arrangement, moreover, gives a good berth on the north side, and generally results in a particularly commodious and serviceable pier.

The new pierhead is 440ft. long by 60ft. wide, whilst the gangway is 170ft. in length, with a width of 40ft., the new works including the formation of a sea-wall from the Castle rocks to the band-stand in front of the Argyll Hotel, a length of about 1000ft.; various waiting-rooms, foot pavements, and other contingent works being included in the undertaking. The pierhead and gangway will be built of timber throughout, the whole of the bearing, fender, and mooring piles of both being of greenheart timber 12in. square. The front, back, and end piles of the pierhead will have a batter of 1 in 16, the remainder of the piles being plumb. The lower and intermediate wales and runners, the lower joists, the diagonals, struts, dwangs, and cleats, will be of greenheart, whilst American rock elm will be employed in the fenders and coping; with the exception of the handrail, all other timber in both pierhead and gangway will be pitch pine creosoted with 8 lb. of oil per cubic foot.

The dimensions of the struts will be 12in. by 8in., those of the cleats for carrying dwangs 12in. by 4in., and the remainder of the greenheart timber 12in. by 6in. The top and bottom horizontal fenders and all vertical fenders will be 12in. by 6in., whilst the intermediate horizontal fender is 8in. by 6in. The coping on the face and ends of the pierhead is 18in. by 9in., and the creosoted pitch pine, upper wales, runners, and joists are 12in. by 6in. The flooring for the gangway will consist of 4½in. thick creosoted pitch pine, that for the pierhead being of the same material ½in. thicker; spikes, 10in. and 11in. long, will secure the planks to the joists of the gangway and pierhead respectively. The spike heads will be driven 1in. below the surface of the planks, the hole thus formed being subsequently run up flush with pitch.

The wales and runners are designed with butt joints on the centre of a pile, all wales, runners, joists, diagonals, and ties being fixed to piles with two bolts at each end of every length of timber, and with one bolt to intermediate piles. The bolts used throughout are 1⅛in. diameter, and of iron. Those fixing top and bottom horizontal elm fenders on the pierhead have square necks and flat heads, the heads being sunk flush with the face of the timber; all other bolts have square heads. The nuts throughout are square, the circular plate washers being 3in. diameter and ¼in. thick. Each vertical elm fender is secured in position by four rag-spikes and four turned oak treenails, the spikes being placed two near the upper and two near the lower end of each fender. Two rag-spikes, one near each end, and two treenails, secure each intermediate horizontal fender in position. The rag-spikes and treenails are each 14in. long, and ¾in. and 1¼in. diameter respectively, both will be driven flush, the latter receiving a coat of white-lead immediately before being driven. A space of ½in. will be left between each plank on the gangway and pierhead flooring.

The connection between the existing and the new pier will be made in a particularly substantial manner, as many of the upper and lower joists as possible being carried right across and connected to the old piles. A pair of horizontal iron straps, 5in. by ¾in., will be carried round and bolted to the corner piles and fenders, the edges of the straps being bevelled, and the ends returned and bolted to the sides of the piles. The pierhead cope is sheathed with plate iron, 2ft. broad and $\frac{3}{16}$in. thick, solidly bedded on the timber, and protected from rust by a coat of archangel tar. The mooring pile heads have cast iron covers, with 1in. metal, the space between the iron and timber being run up solid with pure Portland cement. The gangway and pierhead handrail is designed to be 3ft. 6in. high, the uprights being 4in. by 4in., the top and bottom runners and diagonals 4in. by 2½in., and the rounded cope 5in. by 2in., the uprights being secured by a pair of ½in. bolts to the runners and joists. As will be noted from the accompanying drawings, the pierhead is formed of six rows of piles, varying in length from 50ft. long at the front to 40ft. long at the back.

The sea-wall, where not founded on rock, will be carried on concrete foundations, 12in. in thickness, and will be built of concrete rubble masonry, surmounted by a 16in. by 9in. ashlar coping, carrying a substantial and ornamental railing, which is to receive one coat of anti-corrosive paint before erection, and two coats of oil paint after erection. The pavement inside the sea-wall will have a bottoming of broken stone 4in. deep, the metal being required to pass through a 3in. ring, whilst the pavement surface will have a fall of 4in. from the kerb to the sea-wall. For the granolithic paving, a 3in. layer of ordinary concrete will be formed on top of the broken stones, covered by a finishing coat 1½in. in depth of concrete, composed of one part by measure of Portland cement to two parts of crushed granite passed through a ⅜in. sieve.

The New Pier entrance carriage-way will also be of granolithic paving, the bed of ordinary concrete being 5in. in depth and the granolithic 3in. in depth, the surface of the footpaths being dabbed, and that of the carriage-way being grooved on the track of the horses' feet. The run channel is 20in. broad, formed of square dressed whinstone causeway 3½in. to 4in. broad and 7in. deep, set on a 2in. bed of sharp sand, grouted with lime mortar. The whinstone kerb is designed 12in. by 6in., and is ridged on top face and back edge, the cast iron road gullies being connected with the sea-beach by 6in. diameter fireclay pipes jointed with cement.

Turning now to a brief *résumé* of the materials for the contract, the Portland cement is required to weigh at least 112 lb. per imperial bushel, and when made into briquettes to withstand a tensile strain of 360 lb. per square inch after seven days in water. The concrete employed in the sea-wall will consist of one part by measure of Portland cement, two parts of sand, and two parts of gravel, whilst the cement mortar for setting the coping and for painting coping and walls will be composed of equal parts of Portland cement and sand. The lime mortar used for building the fence walls, grouting causeway, &c., will consist of one part by measure of good lime shells, thoroughly slaked, to 2½ parts of sharp sand, whilst the Arden lime mortar will be formed of one part by measure of freshly ground Arden lime to two parts of sand and one-half part mine dust. The cast iron in the undertaking is required to have a tensile strength of seven tons per square inch, whilst all wrought iron is specified with a breaking strain of 20 tons per square inch. The work, now vigorously in hand, is to be completed within fourteen months at a cost of £15,000, such sum, however, excluding the outlay on waiting-rooms, &c., which is estimated at about £2000. The engineer of the undertaking is Mr. William Robertson Copeland, M.I.C.E., of Glasgow; the contract having been secured by Mr. James Watson, of Bath-street, Glasgow.

NIGHT CHANNEL SERVICES.—We learn that the new and commodious passenger steamer Dover, of the London, Chatham, and Dover Railway Company, will perform the Channel crossing in connection with the night mail service leaving Victoria at 8.15 p.m., and Paris and Brussels at 9.0 p.m. daily from April 1st. This vessel has made many passages during her trial trips in 65 and 70 minutes. The sister ship Calais will be shortly ready to be placed in this service, and it is quite probable that the smaller boats will then be entirely discarded. This company is now running its large boats Calais-Douvres and Victoria in both the 9.0 a.m. and 11.0 a.m services from London daily.

THE INSTITUTE OF JUNIOR ENGINEERS.—This thriving young society, which now has a membership of upwards of 500, held a highly successful conversazione on Saturday last at the Westminster Palace Hotel. A capital programme was arranged, by means of which the members and friends were kept interested for about four hours. Mr. H. L. Tyson-Wolff gave an interesting description of Professor Röntgen's recent discovery, with special reference to the results obtained by Mr. A. A. C. Swinton, who kindly lent lantern slides and photographs for the purpose. Mr. R. W. Paul gave an exhibition of the highly ingenious device known as the "Theatrograph," and Mr. James Rennie contributed a short paper on "Illustrated Newspaper Production." A large number and variety of exhibits were on view, and altogether the institution is to be congratulated upon the success achieved by its first conversazione.

TECHNICAL COLLEGE FOR PAISLEY.—The governors of Paisley Educational Trust having some little time ago resolved to erect a technical college at an outlay of some £17,000, exclusive of site, and having invited competitive plans from a number of architects have now selected the successful design, having been assisted in coming to a decision by Dr. Rowand Anderson, the well-known architect of Edinburgh. Nine separate designs were submitted, the author's identity being under separate cover, and the accepted design was found to be by T. Graham Abercrombie, Gilmour-street, Paisley, who is also the architect of the new infirmary and the Barbour Academy and Grammar School, both in course of erection in Paisley. The plans show a building three stories in height with a frontage to George-street of 120ft., the style of architecture being a simple treatment of Italian classic. The main entrance leads to a spacious vestibule, from which are the principal rooms and offices for janitors. Running east and west of the ground floor is the main corridor, 10ft. wide, and off this are the art masters' rooms, library, and designing room. In the centre of the building is the art lecture hall, in which accommodation will be provided for 300 persons. Grouped round this hall are the art class-rooms, which will be lit from the roof as well as by side windows. Above the ground floor the building becomes L-shaped. On the first floor are the science department rooms with lecture hall, and on the second the chemistry and physical departments, &c.

PROPOSED SHIP CANAL FOR CONNECTING THE BRISTOL AND ENGLISH CHANNELS.

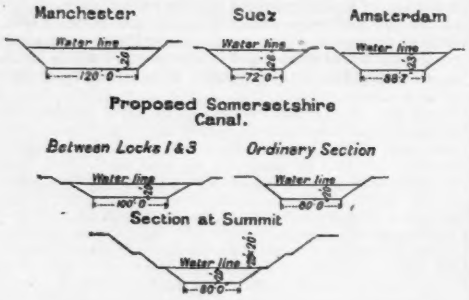
By W. O. E. Meade-King, M. Inst. C.E.

(*Concluded from page 274.*)

The present course of the river Axe from near Axminster is the one best suited for the line of the canal, and as the canal is to be so much lower than the river, it is proposed, by straightening and dredging, to convert the latter into a navigable channel, with locks at Seaton, by which vessels could make use of the canal at all states of the tide. The London and South-Western Railway has to be crossed near Axminster, and for this reason the canal has been kept as low as possible, the formation level being Ordnance Datum; this will only necessitate the railway being raised about 40ft. to give a headway of 75ft., as allowed at the crossing of the Great Western Railway, near Taunton, and the remarks concerning the embankments and gradients of the Great Western Railway apply in every respect to this line.

In these days, when so much is being said about agricultural depression, such a canal would be of immense advantage to what is purely an agricultural County, as a cheap means of despatching its produce to the capital and other large centres of industry, and also for obtaining necessaries for farm labour, for the transport of all of which it is now dependent on the railways, excellent no doubt where time is of vital importance, but the rates of which, being so heavy when compared with water carriage, must necessarily make a large hole in the profits.

It may be interesting to compare the proposed Somersetshire Canal with some already in existence, and the following sketches show three of the best known canals:—



The Manchester and Amsterdam Canals will both allow two of the largest class of steamers to pass each other at any point; in point of width the Somersetshire Canal would do the same, but it is not anticipated that vessels of more than 3000 tons, with a draught of 16ft. or possibly 17ft., will ever be likely to use it, the average steamers probably not exceeding 1500 or 2000 tons, and these having 30ft. or even 35ft. beam, could pass each other at any point easily. The locks are laid out with a view of meeting any future contingencies.

Before leaving the subject of the construction of the canal there are two things that ought to be mentioned, one being the subject of wharves or lay-byes, and the other the means of access from bank to bank of the canal. With regard to the former, all important places, such as Bridgwater, would, of course, be provided with wharves consistent with the probable requirements of the position; Bridgwater having already a certain shipping trade, as previously mentioned, would want something more than wharves, that is, docks, and Taunton has already been mentioned as being provided with docks.

As to the latter, that is means of access from bank to bank, the estimate allows for two swing bridges, one at Bridgwater and one near Taunton, being the two most important places, and both in the lowest part of the canal, and eighteen high level bridges, approaches to which would, of course, be formed by excavated material from the canal. This makes twenty bridges suitable for vehicular as well as pedestrian traffic, in addition to the two high-level railway bridges. The estimate also allows for twenty ferries suitable for foot passengers who would also be able to cross at each set of locks, making sixty-six means of crossing for pedestrians and twenty for vehicles, so that in the forty-three miles of canal no vehicle could be more than a mile at the outside from a point where it could cross, and no pedestrian would be more than about a quarter of a mile from a crossing place. Both entrances to the canal would have to be protected by breakwaters, as much to keep them clear of shifting sand, &c., as to protect vessels entering and leaving from storms; for this purpose a sum of about half a million has been included in the estimate.

Enough has been said concerning the actual construction of the canal; it now remains to show the utility of such an undertaking if carried out. Inland navigation is a subject that has been very much neglected, especially so since the introduction of railways, for one by one the canals or most of them got into the hands of the railway companies, to whose interest it was to let them die a natural death as speedily as possible. It has been already shown the variety of ways in which such a canal would benefit the County of Somerset. First of all, the northern portion of it acting as a waste-water course to take the superfluous drainage in times of flood; the remainder of the canal also would act in a measure in this manner, owing to its being so much below the natural level of the ground, though being through comparatively high land, the surface drainage would find its way into its own ordinary courses much quicker.

And another very important item of saving to the County would be in the rates charged for the carriage of agricultural produce; for instance, at the present time, grain, packed manure, potatoes, and such like things are charged 14s. a ton between Taunton and London, and fresh meat as much as 49s. 6d.; and in order to show what might be saved, let it be supposed that 1000 tons of grain has to be sent from Taunton to London, at the present rate this would come to £700; supposing the canal to be made and the same cargo sent by water, the rates being 1s. 6d. a ton for the canal and 4s. 6d. per ton for the remainder of the voyage, the rate would then come to £300, showing a saving on this cargo alone of £400. As another instance, 100 tons of fresh meat by rail would come to £247 10s.; by the canal, allowing 1s. 6d. a ton for the canal and 7s. a ton for the remainder of the voyage, it would cost £42 10s., showing a saving of £205. According to this estimate, the saving in carriage amounts to nearly 58 per cent. in the case of grain, and rather more than 80 per cent. in the case of fresh meat. It is shown later on, in estimating the financial prospects of the canal, that a charge of 1s. 6d. per ton for the County through which the canal flows is plenty to enable it to pay good dividends, and the charge of 4s. 6d. per ton is about the rate charged now for coal from Cardiff to London; 7s. has been allowed in the case of fresh meat, being more difficult, and therefore more expensive to handle.

But it is not only to the county or counties through which the canal is to pass that its chief benefits are expected to be felt. The shipping trade of the Bristol Channel is said to be one-fifth of the total shipping trade of the whole of England and Wales put together, and a large percentage of this must necessarily now have to round the Land's End, the Cornish coast, as the official returns of wrecks show, being a most dangerous one to all classes of vessels. According to the official register compiled in the Board of Trade, the following wrecks and casualties are approximately the number that took place between the places named during the year ending 30th June, 1891:—

	Strandings.		Collisions.		Other causes		Total.
	Sailing.	Steam.	Sailing.	Steam.	Sailing.	Steam	
Between southern entrance to Somersetshire Canal and Start Point ..	14	5	7	6	12	12	56
Between Start Point and Land's End	21	9	26	11	46	29	142
Between Land's End and Hartland Point	12	6	8	15	43	23	107
Between Hartland Point and northern entrance to Somersetshire Canal..	25	34	27	37	29	27	179
Totals	72	54	68	69	130	91	484

In order to arrive at those numbers, half the registered number of wrecks between St. Catherine's Point and Start Point has been taken as the number between the southern entrance to the Somersetshire Canal and Start Point; the actual registered return has been taken as the number between Start Point and Land's End, and Land's End and Hartland Point, and half the registered number between Hartland Point and St. David's Head as the approximate number that would be effected between Hartland Point and the northern entrance to the canal.

It is not to be supposed that this number of wrecks would be saved by this canal; the shipping trade from and to the Devon and Cornish coasts would of course continue, but probably a safe estimate of wrecks saved would be 50 per cent., as all vessels using the canal would avoid the risk of stranding, and probably collision, and the less the number of vessels passing these coasts, the less the chances of collision for those vessels that would have to use the sea passage in any case, that is whether there was any canal or not.

At the present time not only do all these casualties occur, but boats between the east and west coasts and boats bound for Belfast are often detained for weeks together, being unable, owing to stress of weather, to round the Land's End. Such a canal as that now suggested would at any rate reduce the time occupied in the voyage to a certainty, naturally a very important matter in all commercial undertakings. The Manchester Ship Canal had very serious opposition to it, and very naturally so, from the various railway companies it affected, inasmuch as it formed a competitive source of transport for merchandise, but in this case the railways could not offer any serious objection, not being intended so much to take the existing railway traffic as to shorten the present sea route, and take boats and their cargoes which were going by sea in any case.

A great number of instances might be quoted showing the extent to which distances would be reduced by the canal, but as the following table of comparative distances has been prepared, it is thought that one or two instances will suffice, and these will also explain the table.

Table of Comparative Distances between Points in the Bristol and English Channels.

If 69·5 miles are saved by means of canal, the time occupied in reaching that point is the same either by Land's End or canal.

Note.—All distances are in English statute miles. From Cardiff to point off Ushant by Land's End, 332 miles; from Cardiff to point off Ushant by canal, 320 miles; showing saving by canal of 12 miles, together with increased safety of voyage.

Cardiff being about the most central of the South Wales ports, is a good instance to take first, and it is to be supposed a vessel is trading between that port and London, or any other port on the East Coast. To do so the boat would, of course, have to go through the English Channel, having rounded the Land's End, and having travelled about 331 miles—land miles — would reach a point in the English Channel off Portland which she would reach by means of this proposed canal in 103 miles, which shows a saving in distance of 228 miles, to say nothing of what she might save if there was rough weather in the Atlantic. This point in the English Channel, in the table attached, has been called a common point, and is meant to apply to all boats bound to pass through the Straits of Dover. Swansea, the worst situated of all the Bristol Channel ports, so far as this canal is concerned, being the nearest one to the open sea, and farthest from the entrance to the canal, would nevertheless save 173 miles in reaching this common point by use of the canal; while Bristol would reap the greatest benefit, effecting an actual saving of 240 miles. These distances hold good for all vessels trading between the Bristol Channel and Northern Russia, Sweden, Norway, Denmark, Germany, Holland, and Belgium, while the trade with the Channel Islands and France would also be affected, much to the credit of the canal; for instance, take Cardiff and Guernsey, at the present time 320 miles apart, but by the canal only 148, saving by that means 172, and to the Hague from Cardiff a boat by the canal would save 202 miles, to the Havre 226, and to Dieppe 224, each amount saved being as a rule rather more than a half of the distance it has at present to travel.

But while on the subject of distances there is another point well worthy of careful consideration. Within the last few months a new line of steamers has been started to run between Manchester and London, the traffic per week already amounting to about 1500 tons each way, and showing unmistakeable signs of increasing; the continental traffic also amounts to at least 2500 tons a week. The whole of this might be estimate to make use of the canal, inasmuch as the distance from a point off St. David's Head to the common point in the English Channel, *viâ* the Land's End, is about 295 miles, and if by the Bristol Channel and Somersetshire Canal, 216 miles, thereby saving 79 miles in distance, with an estimated saving of time, as will be explained hereafter, of two hours, also saving certain light dues, and with the advantage of avoiding the Devon and Cornish Coasts. And if it can be satisfactorily proved that vessels trading between Manchester and London would find it to their advantage to make use of this canal, there is really no limit to the trade that might pass through it, so far as the West Coast of England, the Irish ports, and the South Coast of England east of Seaton, the North of France, and everything east of the Straits of Dover, were concerned. There is yet one other instance coming under the headings of distance saved by the canal; it is very slight, but nevertheless a saving. From Cardiff to a point off Ushant by the Land's End is about 332 miles, and by the canal 320, a difference of 12 miles in favour of the canal in point of distance, but the canal route would enable a vessel to travel between 50 and 60 miles of her voyage quite protected by the canal and coasts of Devonshire from the furies of an Atlantic storm, and if the canal was adopted in this case, it opens another and still larger field for trade, taking as it would the Spanish and Portuguese trade, and everything that of a necessity would pass through the Straits of Gibraltar.

So far as time is concerned, which, according to shipowners, is of the utmost importance, allowing that the average rate of a collier is eight and a-half miles per hour, in the case of a boat between Cardiff and London, it would take her 38·94 hours to reach the common point in the English Channel by the Land's End route, and by the canal allowing only four miles per hour for forty miles of the canal, ten minutes for each set of locks and eight and a-half miles per hour for the portion of sea route—about 57 miles—she would have to travel, it would take her 21·03 hours to reach the same common point, showing a point in favour of the canal of 17·91 hours—say eighteen hours—on that portion of her journey, and all this in addition to the fact that her voyage would be reduced to a certainty, humanly speaking, and without incurring the risks she would otherwise run off the dangerous coast previously alluded to. To continue the question of the saving of time, the eighteen hours, of course, is on one journey only; on her homeward voyage it would be repeated, thus making a saving of thirty-six hours on her trip; and to continue the argument, supposing a collier arrives at Cardiff on a Saturday morning *viâ* the canal, she could take in her cargo of coal and be off to sea again before the Sunday, when by the present existing route she might not be able to get to Cardiff before the Saturday night, or at any rate too late to take in her cargo, thereby losing Sunday and possibly Monday as well.

It now remains to be seen what the financial prospects of such a canal, if carried out, are like. The port of Swansea, having supplied the most complete returns of any of the South Wales ports, is taken as an example, details being given of it, and the other South Wales ports are worked out having Swansea to go upon as a basis. The shipping of these ports has increased enormously; for instance, in Swansea the exports of coal and coke in 1862 amounted to 700,866 tons, and in 1893 they amounted to 1,459,475 tons, showing an increase of 758,609 tons. The exports of patent fuel in 1862 came to 92,134 tons, and in 1893 360,960 tons, showing an increase of 268,826 tons. In tin-plates the exports in 1878 came to 12,425 tons, and in 1893 275,030 tons, showing an increase of 262,605 tons. These are only three instances of the trade done. The total tonnage—dead weight—of imports and exports are as follows:—

	Imports. Tons.		Exports. Tons.		Total. Tons.
In 1862	369,700	..	914,000	..	1,283,700
In 1893	589,791	..	2,216,418	..	2,806,209
Showing an increase.. ..	220,091	..	1,302,418	..	1,522,509

It has now to be calculated how much of this tonnage could be fairly expected to make use of the canal, and the following shows in a concise form the countries traded with and the amounts, from which table can be taken the exact tonnage that would have had to pass through the Straits of Dover.

The figures given are the official returns for the port of Swansea for the year 1893.

	Imports.	Exports.	Total.
Russia (North, say)	5,550	32,927	39,477
Sweden, Norway, and Denmark	16,780	61,051	77,831
Germany, Holland, Belgium	5,371	83,210	88,581
Channel Islands	1,011	16,006	17,017
France	41,397	655,848	697,245
Total	70,109	851,042	921,151
Portugal, Gibraltar, Malta, Madeira, Spain, Italy, Austria, Greece, Roumania, Algeria, Turkey, Egypt, Morocco, Cape of Good Hope, East and West Africa, Java, Ceylon, and Japan	154,547	455,125	609,672
South Russia, say	5,550	32,927	39,477
North America, West Indies, and South America	60,601	421,342	481,943
Total foreign trade	290,807	1,759,436	2,050,243
Coastwise	298,984	456,982	755,966
Total	589,791	2,216,418	2,806,209

The total Russian trade amounted to 11,100 tons of imports and 67,854 tons of exports, and for the sake of this paper, half the imports have been taken as coming from North Russia, and therefore through the Straits of Dover, and the same has been done with the exports. This makes the foreign trade which may be counted upon as using the canal amount to—

	Imports.	Exports.	Total.
	70,109	851,042	921,151
In addition to which the coasting trade has to be taken into account, and to be on the safe side, only half the total imports and exports have been taken as likely to go south, making	149,492	228,491	377,983
Total	219.601	1,079,533	1,299,134

	Tons per annum.
Therefore out of the total amount of shipping of 2,806,209 tons, 1,299,134 tons—or rather more than 46 per cent.—may be calculated upon to pass through the canal, but in order not to raise false hopes or appear too sanguine, 45 per cent. only will be allowed for, which makes the shipping to and from the port of Swansea likely to use the canal equal to	1,262,749
It is now necessary to consider what may be reckoned on from Barry, Penarth, Cardiff, and Newport, these being the other most important South Wales ports, taken in their order travelling east from Swansea. At Barry the *average* shipping trade per week done for four weeks in April and May, 1894, amounted to 105,008 tons—45 per cent. of which amounts to 47,253 tons. To allow for holidays, the year is taken as 50 weeks. Therefore Barry trade through the canal per annum ought to be	2,362,650
Average at Penarth, in same way, 37,327 tons per week—$\frac{37,327}{45 \text{ per cent.}} = 16,797 \times 50$ weeks	839,850
Average at Cardiff, in same way, 300,000 tons per week—$\frac{300,000}{45 \text{ per cent.}} = 135,000 \times 50$ weeks	6,750,000
Average at Newport, in same way—five weeks taken, coasting trade only—19,675 tons per week—$\frac{19,675}{45 \text{ per cent.}} = 8853 \times 50$ weeks	442,650
Trade between Manchester and London, 3000 tons per week × 50 weeks	150,000
Between Manchester and Continent, 2500 tons per week × 50 weeks	125,000
Shipping trade from Bristol, Avonmouth, and Portishead for year 1893-4 = 779,483 tons, 45 per cent. of which =	350,767
Total through traffic	12,283,666

Inland Traffic.

	Tons.	Tons.	Tons per annum.
Bridgwater—			
Imports—Coasting	149,396		
Foreign	14,249		
		163,645	
Exports—Coasting	49,207		
Foreign	1,987		
		51,194	
Total			214,849
Taunton—			
Anticipated			30,000
			244,849

Of course, if it was considered advantageous for vessels bound for Gibraltar to make use of the canal, the numbers given would be very largely increased; but in order to be on the safe side none of this shipping has been taken into account; and as Sharpness, Gloucester, Worcester, and many other places, all of whom transmit their share of shipping to the English Channel, have not been taken into account, though they rightly might be, nothing has been deducted from the figures given for contingencies.

The estimate for the canal is as follows:—

Approximate Estimate.

Description.	£	£
Purchase of land—		
For canal	688,000	
For railway deviations	20,400	
For reservoirs	50,000	
Total for land		758 400
Earthwork—		
Including excavation of canal and river diversions, dredging, railway and canal embankments, and puddle walls, &c. &c.		3,143,231
Pitching, slopes of canal, &c.		404,000
Fencing		19,800
Locks		1,990,000
Bridges—		
Swing	54,000	
High level	324,000	
		378,000
Ferries		2,000
Railway deviations, including bridges		250,000
Dock walls		132,000
River weirs		15,000
Reservoirs and pipe tracks		500,000
		7,592,431
Add for contingences, 10 per cent.		759,243
Total for works and land		8,351,674
Parliamentary expenses		200,000
Engineering expenses		275,000
Legal expenses		30,000
Total approximate estimate		8,856,674

But in order to simplify matters, as well as to be on the safe side, the capital for present purposes may be called £9,000,000, and this may be divided as follows:—4 per cent. debentures, £1,000,000; 6 per cent. preference, £4,000,000; ordinary shares, £4,000,000; total, £9,000,000. The question of rates is one that would have to be determined in time to come, but as the lowest rate at present for canal traffic is about 1d. a ton per mile, it will be on the safe side to estimate traffic in this case at about ½d. a ton per mile, or, say, 2s. a ton for the whole canal.

	£	s.	d.
Through traffic, amounting to 12,283,666 tons per annum, carried at this rate would yield	1,228,366	12	0
Inland traffic of 244,849 tons at 1s. 6d. would yield	18,363	13	6
Giving a gross revenue of	1,246,730	5	6
Deduct working expenses 40 per cent.	498,692	5	6
Leaving net revenue	748,038	0	0

	£
4 per cent. on £1,000,000 debentures absorbs	40,000
6 per cent. on £4,000,000 preference absorbs	240,000
8½ per cent. on £4,000,000 ordinary absorbs	340,000
Leaving amount to be carried forward	128,038
	748,038

The only figure not taken from actual returns in the whole of the above estimate is the anticipated amount of trade done at Taunton, and as docks are intended to be there, owing to its being the most important town *en route*, 30,000 tons per annum cannot be said to be an excessive amount to anticipate, and so far from estimating a profit from dock dues, the whole of the inland traffic—that is, Bridgwater, Taunton, &c.—has been put in at only 1s. 6d., which is to pay for the portion of the canal they must necessarily use.

Attention ought also to be called to the amount deducted from the gross profits for working expenses. No canal or dock working expenses ought to come to more than 35 per cent. of the gross profits, but in this case 40 per cent. has been deducted, a figure which may safely be said to be in excess of that required.

All the points mentioned at the commencement of this paper have now been dealt with; the scheme has been described, and that it is perfectly feasible or practicable there can, I think, be no doubt. It is believed that the arguments in favour of the scheme, as stated in this paper, will considerably outweigh any arguments its enemies may bring against it, and it only remains for shipowners and others to make use of the canal to the extent estimated to prove its financial success.

TRACTION ENGINES ON ROADS.

THE Select Committee of the House of Commons appointed to investigate the working of the laws affecting the use of traction engines on roads sat for the second time on Thursday, the 26th ult., in Committee Room No. 13, when the first witness called was Lord Ancaster, a large employer of steam traction in Lincolnshire for agricultural purposes. The substance of the evidence given by the witness was to prove that traction engines had been employed by him since the year 1878 for hauling purposes, with a considerable saving of money. In 1879 he was involved in litigation with the local authorities for "extraordinary" traffic, the said traffic consisting in the use of locomotives for hauling wagons containing bricks to and from some farm buildings which he was erecting for the convenience of the farmers on his estate. The result of the litigation was that he had to take over the road said to be injured, and also pay certain costs. He had on several occasions since had to compensate for wear and tear of roads.

Mr. Edison, a director of Messrs John Fowler and Co., Leeds, was the next witness called. In answer to the chairman, Mr. Hobhouse, Mr. Edison informed the Committee that his firm had an annual output of more than one hundred road locomotives for use in England alone. He stated that the style of engines had altered very materially during the last thirty years, and that the wheel base had been much shortened, the motion and gearing all covered in, the tanks for carrying the feed-water enlarged, the steerage better arranged, and that by means of the differential gearing employed these engines were much more easily driven round corners than formerly. Roughly speaking, the weights of their engines are—6-horse power engines, 8 to 9 tons; 8-horse power engines, 10 tons; 10-horse power engines, 12 tons; and steam ploughing engines about 16 tons.

Questioned as to the hauling of trains of wagons on the roads, witness stated that there had not, so far as he knew, been any difficulty in this matter, and did not think that it was necessary to limit the number of wagons by statute. With regard to the clause in the statute relating to the type of wheels employed on engines, he suggested that this might with advantage be made more elastic, so that wheels suitable for the particular districts in which they were used might be employed. As an instance illustrating the necessity for this modification of the law, he mentioned that in Lancashire the present wheel with transverse bars had been found very unsuitable owing to the damage done to the hard pavements general in the streets. A model wheel was exhibited to the Committee having wood blocks round the rim, and this had been found to answer the requirements on such pavements admirably. With regard to wagon wheels, it is usual to arrange these so that the back wheels break gauge with the front ones, and that the gauge be narrower than that of the engine wheels, so that the effect of an engine and wagon passing over a road was to roll and solidify it. Mr. Edison considers that an inclusive licence fee of £10 should be sufficient to cover the whole of the country. He thinks that a differentiated fee upon engines above and below 10 tons would be a suitable arrangement, and that traction engines might with advantage be permitted to travel through towns at the same speed as ordinary traffic. The use of steam traction in agricultural districts would be greatly extended if the close hours were more uniform in adjoining counties, and other restrictions removed, while by raising the quality of all roads these would be improved rather than injured by road locomotives. As an instance proving the veracity of this statement, Mr. Edison pointed out to the Committee a certain road in Leeds upon which steam traction engines were constantly plying.

Mr. Allen, manager of the Oxfordshire Steam Ploughing Company, owning forty agricultural engines, in his evidence stated that a great increase had taken place during recent years in the number of engines employed for thrashing purposes. The witness informed the Committee that there were no close hours in the district where their engines were chiefly employed, and no complaints had been made respecting the movement of engines during the night. A great inconvenience was felt by owners of road locomotives in not being able to pass through the City of Oxford during the daytime, between the hours of 10 a.m. and 6 p.m. With regard to the licence fees, the three adjoining counties—Oxfordshire, Berks, and Bucks—each imposed the maximum duty of £10 if a licence is taken out for one of these only, whereas by taking out a licence in each of the three this sum was sufficient to cover the whole owing to the system of rebates. The following are the charges made by his company for agricultural purposes:—Ploughing, 7s. to 12s. per acre; thrashing, 30s. per day.

Mr. Fearnley, the manager of the Barnsley and District British Co-operative Society, next detailed the use this society made of traction engines, and complained chiefly of the restrictions of hours and types of wheels. The former in Barnsley are from 5 p.m to midnight.

On Monday, the 30th ult., four witnesses were called, the first being Mr. R. Bomford, a farmer of 4000 acres of arable land in Worcestershire and Warwickshire. Mr. Bomford stated that he owned six sets of steam ploughing plant, two road locomotives, and four road rollers, and considered that for haulage purposes the traction engines effected a saving of 30 per cent. over horse haulage. Referring to the nature of the roads in his district, the witness stated that those of Gloucestershire were mainly good, but in Warwick and Worcester chiefly poor. Nevertheless, he had not found that his engines did any damage, but rather improved the surfaces. Speaking of licence fees, these were as follows:—Gloucester, £10 for 10-ton engines, and £8 for 8-ton engines, subject to no rebate; but Warwick and Worcester each allowed a rebate of £5, if a licence had already been granted in a neighbouring county. The common complaint of want of uniformity in the close hours was made by this witness, who also considers that two men to each engine are ample to secure the public safety. Respecting the hauling of loads, the Warwick County Council prohibited the haulage of a greater weight than 12 tons net, a limit which ought to be increased to 25 tons. This weight the witness has repeatedly dealt with without damage to the surfaces of roads. He estimated the saving effected by steam traction over horse traction as 50 per cent. on heavy roads over eight miles, and 25 per cent. for short journeys. The following figures are given by Mr. Bomford as illustrating the relative cost of steam and horse haulage:—Horses, 8·2d. per ton mile; steam, 5·25d. per ton mile.

Mr. Cripps, solicitor, and town clerk of Tunbridge Wells, in his evidence stated that he had considerable experience of the working of the laws relating to traction engines, and strongly urged that the power to make bye-laws should be taken away from the county authorities and placed in the hands of a central authority. As bearing upon this he produced a new code of bye-laws recently proposed by the Kent County Council, some of which he considered vexatious and liable to hamper the steam hauling industry. As these have not yet come into effect, it will not be necessary to give them *in extenso*. Mr. Cripps considers that the words "on foot" in Section 29 of the 1878 Statute should be struck out, and cited a case of litigation in which the man preceding the engine had been provided with a cycle, was held to be contrary to the wording of the Act; although it was held that it would be legal for the man to lead a horse and cart. Respecting close hours, the witness holds that these are necessary, but should be universal. In Tunbridge Wells traction engines were prohibited between the hours of 10 p.m. and 6 a.m. which he considers as being the most suitable hours. On the subject of licence fees, Mr. Cripps advises that a levy be made on traction engines, and the same be distributed to the local authorities in which the engines are licensed. Questioned by the Chairman respecting Section 23 of the Highways and Locomotives (Amendment) Act, 1878, the witness maintained that the term extraordinary traffic applied to all kinds of traffic, but considers that, according to the wording of the Act, if a locomotive be used on any road on which such form of traction had not been employed previous to the said Act, such use is liable to be considered extraordinary traffic. An injustice in the administration of the law was pointed out in the case of certain owners of a traction engine who had been allowed the use of a road for seven years before the authorities came down upon them for damages over the whole of that period for extraordinary traffic. Mr. Cripps suggests the altering of the law so that such claims should be made within a specified time—say, twelve months.

Mr. Walter Carter, the well-known carrier of Manchester, was the next witness to give evidence, in the course of which he complained of the annoyance and expense he was put to owing to the arbitrary arrangements made by the different authorities with regard to the close hours. Mr. Carter is the owner of seven traction engines, each weighing 20 tons, which are chiefly employed in the transport of heavy boilers. Notwithstanding the express wording of the 1878 Act relating to the type of wheels used on engines, he informed the Committee that his engines were licensed with wheels on which the Bolton blocks are employed instead of bars, and caused considerable amusement by stating that one of the bye-laws made by the authorities of Ashton-under-Lyne required a toll of five shillings for each engine passing through the town unless the wheels are shod with the above-mentioned illegal blocks. Another bye-law made by the town of Bury necessitated that an owner of a traction engine going through this town should deposit a sum of £100, presumably to cover the cost of repairing the damage done to roads. The prohibited hours which affected the working of his plant are as follows:—Manchester, 9 a.m. to 5 p.m.; Salford, 9 a.m. to 5 p.m.; Bolton, 9 a.m. to 5 p.m.; while other places prohibited during the hours between 5 p.m. or sunset and midnight. The licence fees are:—Lancashire, £5; Cheshire, £10; and West Riding of Yorkshire (if the engine be licensed elsewhere), 1s. per annum.

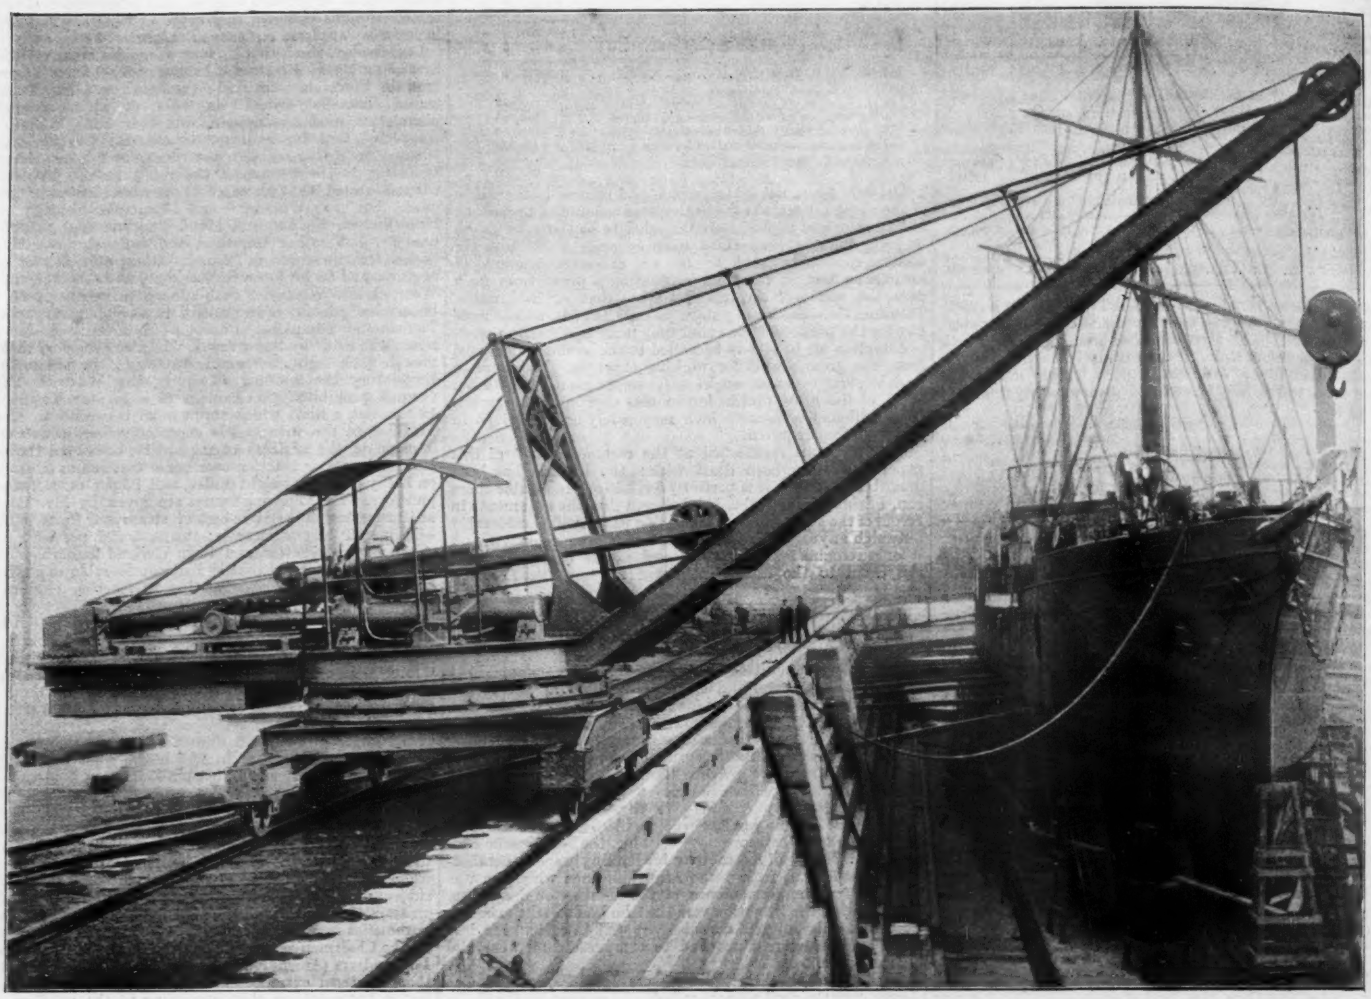
Mr. Mornement, a farmer residing at Thetford, was the last witness called, and generally confirmed the earlier witness respecting the economy of steam haulage, but suggested that the maximum limit of speed should be increased to at least six miles per hour outside of towns and three miles inside. He stated that in the counties of Norfolk, Suffolk, and Cambridge no licence fees were charged.

The Committee then adjourned till the 16th inst.

CHESTERFIELD AND MIDLAND COUNTIES INSTITUTION OF ENGINEERS.—A general meeting of the members of the Institution will be held in the Municipal Science College, Green-lane, Derby, on Saturday, 4th April proximo, at 3 p.m. The following papers will be read or taken as read:—"How a Mine may be Dry, but not Dusty," by Mr. George Fowler; "The Yorks and Notts Coalfield. Geological Suggestions Relative to its Eastern Extension," by Mr. W. S. Gresley. The following papers will be open for discussion:—July, 1895.—"Photometric Value of, and Notes upon, various Illuminants used in Mines," by Mr. A. H. Stokes. Fed. Inst. "Trans.," vol. x., pages 135 and 438. December, 1895.—"Fencing Gates for Winding Shafts," by Mr. William Hay. December, 1895.—"A Boring below the Blackshale Coal at Apperknowle, near Sheffield," by Mr. G. E. Coke. February, 1896.—"The Vibromotor as applied to the Screening of Small Coal," by Mr. Emerson Bainbridge, M.P. February, 1896.—"Lead and Lap of Winding and other Engines," by Mr. Hargrave Walters. February, 1896.—"The Eastern Limits of the Midland Coalfield," by Professor Ed. Hull, F.R.S

TEN-TON HYDRAULIC CRANE

MESSRS. FIELDING AND PLATT, GLOUCESTER, ENGINEERS



TEN TON HYDRAULIC CRANE.

The 10-ton hydraulic dock crane illustrated by the above engraving has been at work for some time past at the new graving dock of the Wallsend Slipway Company. The adoption of a crane of this type for putting the machinery on board new steamers is due to the initiative of Mr. Wm. Boyd, managing director of the Company, and the crane was designed jointly by the late Mr. R. H. Tweddell and Messrs. Fielding and Platt, who have built it. The crane is capable of lifting the load mentioned through a height of 50ft., and it is fitted with a treble ram arrangement, by means of which it can be used to lift 3⅓ tons and 6⅔ tons also, with a corresponding reduction in the consumption of power.

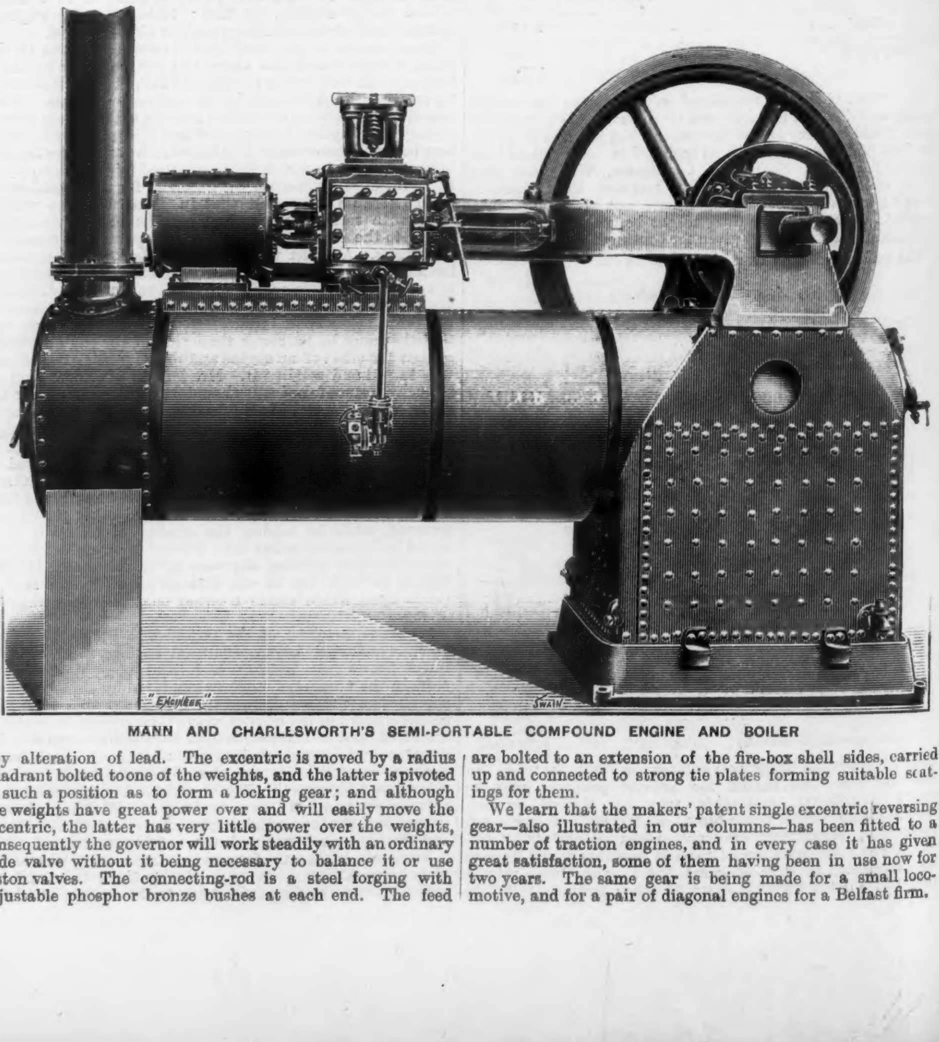
The crane is slewed by hydraulic pressure also, through rather more than a complete circle. The crane can be worked at any point around the sides of the graving dock, suitable pressure hydrants being provided at intervals. The whole arrangement of the crane on the turntable is well balanced, rendering the use of holding down clips unnecessary. A platform is provided for the man working the crane, who has complete control of the valves whilst he faces the load being lifted.

SEMI-PORTABLE TANDEM COMPOUND ENGINE AND BOILER.

We illustrate by the accompanying engraving a new type of engine made by Messrs. Mann and Charlesworth, of Leeds. It is a self-contained tandem compound, which, although quite independent, is shown mounted upon a boiler of locomotive type, forming a compact and substantial semi-portable engine, or, if desired, the engine may be bolted upon a stone or concrete foundation as a separate horizontal engine.

Side-by-side cylinders or double-crank compound semi-portables are frequently met with, but this is the first we have seen of the tandem type, with the engine self-contained and quite independent of the boiler. It has few working parts, and to secure simplicity it is fitted with the makers' automatic expansion gear, which we illustrated in The Engineer of July 5th last. It is also, we are informed, very economical in the consumption of steam.

The following is from a specification of the engine and boiler :—The cylinders are—high-pressure, 7in. diameter ; low-pressure, 11in. diameter ; stroke, 12in. The high-pressure cylinder is steam jacketed, and both are covered with non-conducting material cased with steel sheeting. They are connected and firmly tied together by the firm's improved double cover, which is made so that it may be drawn out of the other end of the low-pressure cylinder, in order to examine or take out the high-pressure piston. These covers being cast together, and having turned projections on them accurately fitting into the end of each cylinder, ensure the latter being concentric and perfectly true with each other. The bed-plate is of the double girder type, and is self-contained, relieving the boiler from all the working strain of engine, and requires no outside bearing. The crank shaft brasses, adjustable by wedges, are of gun-metal, with large wearing surfaces. The barrel part is bored out to form guides for the cross-head, and the flange forms the front cover of the high-pressure cylinder, into which it is recessed in order to get them perfectly true with each other. The crank shaft is 4in. diameter, bent out of a round steel bar, and is of sufficient length for the fly-wheel to be put on either side. The speed of the engine is controlled by the patent variable expansion governor, acting direct upon the slide valve of the high-pressure cylinder. The excentric is carried in a very similar manner to single excentric reversing gear, and automatically cuts off steam from nil to five-eighths of the stroke without any alteration of lead. The excentric is moved by a radius quadrant bolted to one of the weights, and the latter is pivoted in such a position as to form a locking gear; and although the weights have great power over and will easily move the excentric, the latter has very little power over the weights, consequently the governor will work steadily with an ordinary slide valve without it being necessary to balance it or use piston valves. The connecting-rod is a steel forging with adjustable phosphor bronze bushes at each end. The feed pump is fitted with gun-metal valve boxes, and phosphor bronze valves, and pumps the water through a feed-heater which is raised in temperature by the exhaust steam, the water thus entering the boiler a few degrees under boiling point. The boiler is constructed of steel plates, and strongly stayed for a working pressure of 140 lb. It contains 164ft. of heating surface and 7·5ft. grate area. The cylinders are fastened to a wrought iron fixing so that no studs or bolts enter the steam space, and the feet of the crank shaft bearings are bolted to an extension of the fire-box shell sides, carried up and connected to strong tie plates forming suitable seatings for them.

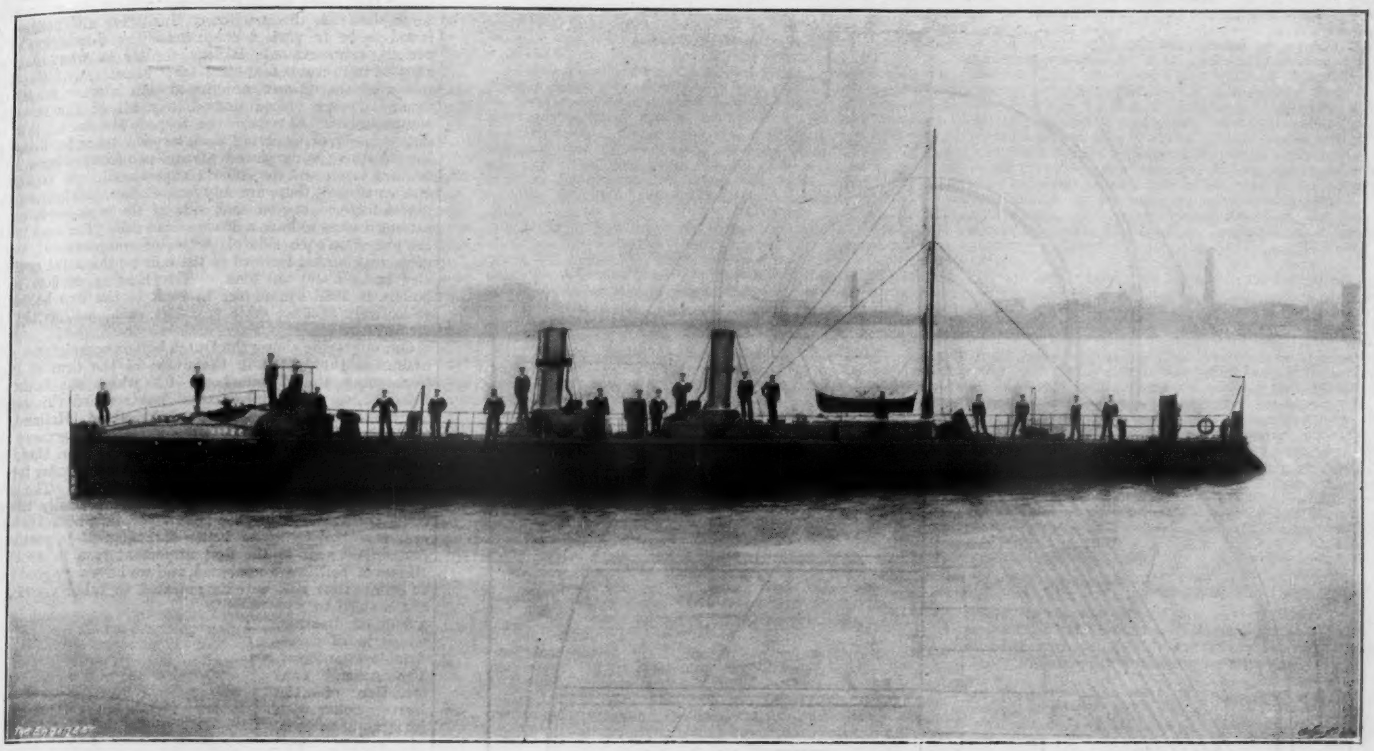


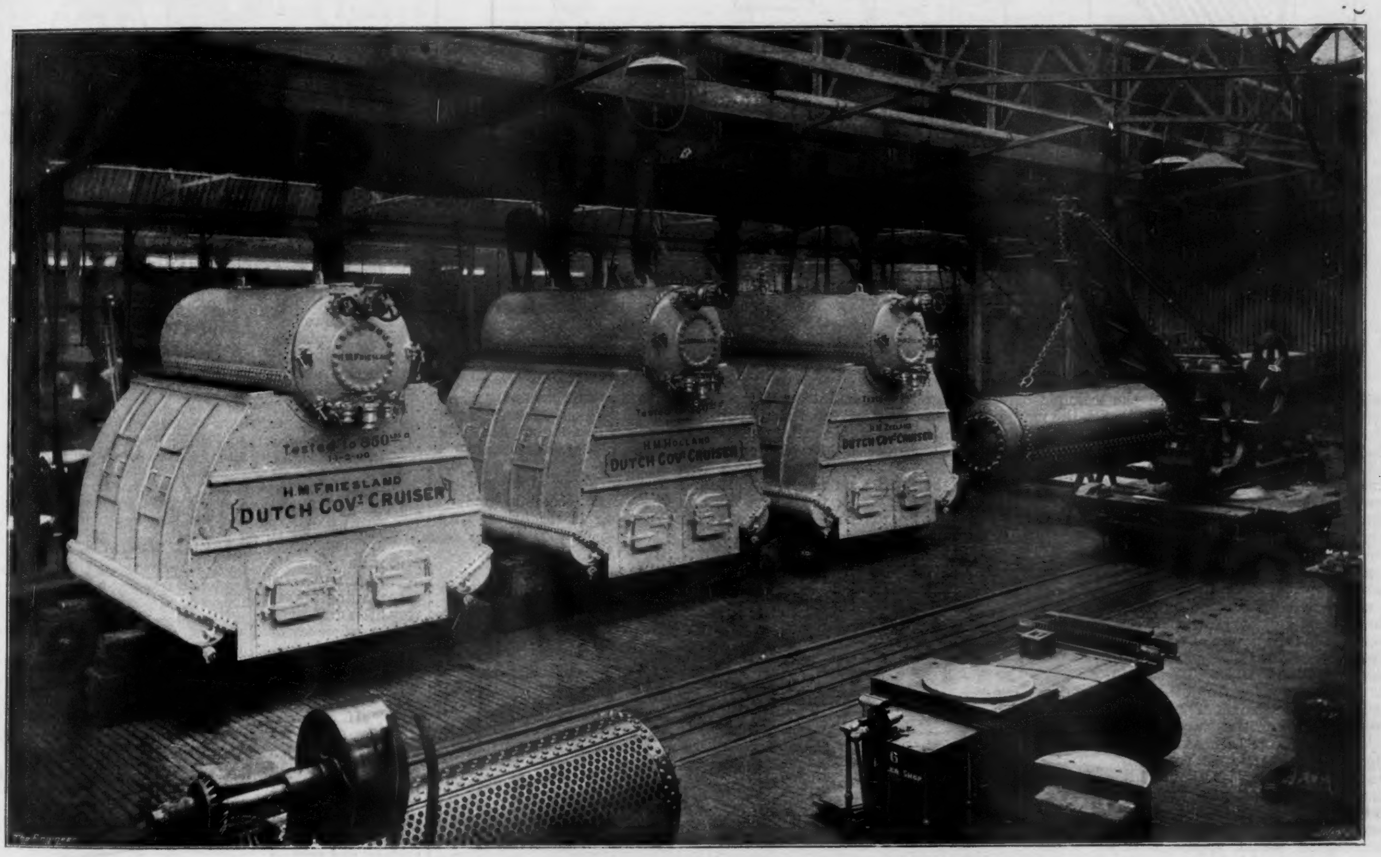
MANN AND CHARLESWORTH'S SEMI-PORTABLE COMFOUND ENGINE AND BOILER

We learn that the makers' patent single excentric reversing gear—also illustrated in our columns—has been fitted to a number of traction engines, and in every case it has given great satisfaction, some of them having been in use now for two years. The same gear is being made for a small locomotive, and for a pair of diagonal engines for a Belfast firm.

THE AUSTRIAN TORPEDO BOAT VIPER

MESSRS. YARROW AND CO, POPLAR, BUILDERS AND ENGINEERS





YARROW WATER-TUBE BOILERS FOR DUTCH CRUISERS

THE AUSTRIAN TORPEDO BOAT VIPER.

THROUGH the courtesy of Messrs. Yarrow and Co., we are enabled this week to illustrate the Viper, a large torpedo boat recently built by that firm for the Austrian Government, and a set of boilers constructed for the Dutch Government, which are similar to those in the Viper. The trials of this craft took place on the 5th of February last, in the presence of Chevalier Leopold von Jedina, Naval Attaché; M. Krainer, Engineer-in-chief to the Austrian Navy; Captain Padevit; M. Thiel, naval architect; and Lieutenant Schwarz and Mr. Nitsch, the future commander and engineer respectively of the vessel. The Viper is 147ft. 6in. long and 14ft. 9in. beam, and was guaranteed to attain a speed of 24 knots when fully equipped and in the loaded condition. With 26 tons deadweight on board to represent her armament, &c., the vessel left Poplar at 10 a.m., and on arriving at Thames Haven about noon commenced a three hours' continuous trial, during which six consecutive runs were made on the measured mile. A speed was attained on these runs of 26·633 knots. The boilers of the Viper are of the Yarrow water-tube type. The scheduled particulars of the run are given in the following table:—

Hour.	Steam in boilers.	1st R.	2nd R.	Vac.	Air P.	Revs. per min.	Time.	Speed.	Mean.	2nd means.	Notes.
							m. s.				
1·36	175	69	11	25	·875	379·84	2 10	27·692	26·703		Lower Hope.
1·43	175	69	16	25	·875	378·00	2 20	25·714	26·597	26·650	
1·51	173	68	10	25	·875	382·86	2 11	27·480	26·975	26·786	26·633 Slip 11·3 p.c.
1·57	173	68	10	25	·75	386·46	2 16	26·470	26·373	26·674	I.H.P. 1940
2·3	173	68	10	25	·75	362·19	2 17	26·277	26·471	26·422	
2·10	175	70	11	25	1·	390·00	2 15	26·606			
Means	174	69	10·5	25	·875	379·89	—	26·716	—		

After these runs, went down to the Maplins and back. Accepted mean revolutions for the three hours 379·888 per minute. Accepted mean speed 26·638 knots.

The Viper has since safely made her passage from the Thames to Pola. Her sea-going qualities were thoroughly tested on the passage out, as she experienced excessively rough weather in the Bay of Biscay. As a general rule in her Majesty's service first-class torpedo boats are convoyed by vessels of large size, but in the present instance the Viper made the passage from England to Austria unattended. This vessel attained on her trial on the Thames a speed, as shown above, of 26·6 knots with only ⅞in. air pressure in the stokehold, and it is instructive to draw some comparison between this result and those obtained with the destroyers, about which we have heard so much of late.

The object of the destroyers was to overhaul the torpedo boats, but it will be seen with the example of the Viper before us there cannot be said to exist the margin of speed between the two types of vessels which is generally believed. The weight carried on trial by the Viper was 26 tons, on the 27-knot destroyers the load carried is 30 tons, and on the 30-knot torpedo-boat destroyers 35 tons. From this it will be seen that the loads named are favourable to the speed of the destroyers, because to compare them on the same basis it is only correct that the load should be in proportion to the displacement and power to ensure a proportionate range of action and fighting power. The 27-knot destroyers will be about double the power of the Viper, and double the displacement, and the 30-knot destroyers about three times the power and displacement. Therefore to compare the various types on the same basis as the Viper which carried 26 tons, the 27-knot destroyers should carry 52 tons, and the 30 knots 78 tons; and if this load were carried on board the destroyers their speed would approach very near to that of the Viper.

No doubt the destroyers will have the advantage in rough weather owing to their better sea-going qualities, thanks to their size, but we greatly doubt whether the increased length of from 150ft. in the torpedo boat to 200ft. in the destroyers, will be sufficient materially to modify the comparative merits of the two types of vessels as regards speed in rough weather. Moreover, it must be borne in mind that in vessels of this type, which are quite unprotected, the destroyers expose a much larger area to the enemy's fire than the torpedo boats, and for this reason the larger vessels are the more vulnerable and more likely to be disabled in action. If the 27-knot destroyers were loaded with their proportionate load, there would probably be very little difference in speed between them and the first-class torpedo boats, and if the 30-knot destroyers were also proportionately loaded the probable difference in speed would not amount to more than 2 knots.

YARROW WATER TUBE BOILERS
YARROW WATER TUBE BOILERS

ARRANGEMENT OF SCOTCH AND YARROW BOILERS IN DUTCH CRUISERS

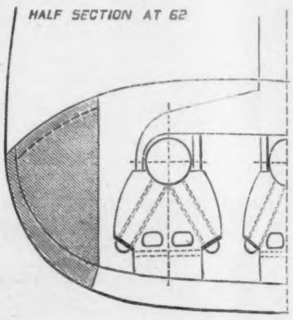
Now, assuming that a 30-knot destroyer were chasing a first-class torpedo boat, and the latter had the start of the former to the extent of ten minutes, which would give the torpedo boat a start of 4 knots, it would take about two hours for the one to overtake the other, during which time we may presume that both vessels would be firing at each other, and it is not unreasonable to suppose that under these circumstances the destroyer with its larger area exposed to shot would suffer most, and we very much doubt whether in practice the destroyer would get the best of the combat in a two hours' race.

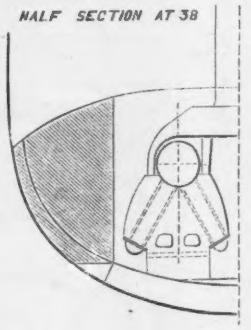
It should be borne in mind that in the naval manœuvres in which the destroyers and the torpedo boats have taken part, the former have the most improved machinery with water-tube boilers, and the latter are more or less boats of an obsolete type built years ago. The comparison would be very different if made between vessels in which modern improvements were introduced. Consequently, it becomes with the present light a question for Governments to consider how far they are justified in building vessels of the destroyer type, when the same expenditure of money would enable them to get two or three times the number of first-class torpedo boats. This is a matter rather for the naval officer than the engineer to decide.

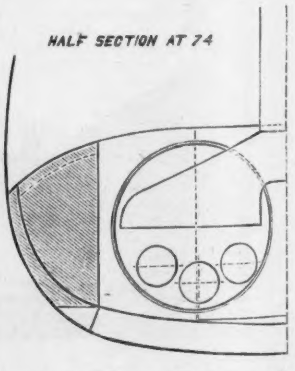
Returning now to the Viper, we may say that she has a single screw, and the engines indicated from 1900-horse power to 2000-horse power. The very low air pressure required to obtain this speed bears testimony to the great boiler power. After the run, the machinery, including the boilers, was found to be in perfect condition. The disposition of the various compartments is very similar to what has been adopted in previous first-class torpedo boats, with the exception that the officers' accommodation is more ample than usual, it being placed immediately aft of the machinery compartment. As regards the torpedo armament, that consists entirely of revolving deck torpedo tubes for firing over the sides, one being placed aft and two forward between the conning tower and the boiler compartment. As regards the gun armament, there are only two 47 mm. quick-firing guns, placed forward, one on each side of the conning tower, and arranged so as to have a direct-ahead fire. The coal bunkers are placed on each side of the boiler compartment, and one cross coal bunker forward of the boilers, the total coal capacity being about 30 tons. The heating surface in the boilers is 1868 square feet in each of the two boilers, *i.e.*, collectively 3736ft.; grate area 35ft. each, collectively 70ft.; air pressure ⅞in.

Our engraving shows the Dutch boilers complete with their casings as they stood in the works of the firm at Poplar. Concerning the Dutch boats for which the boilers are intended, very little information has reached this country. They are three cruisers, named Friesland, Holland, and Zeeland. The diagrams show the general arrangement of the boiler compartment, from which it will be seen there is an installation of two boilers of the old return tubular type and eight of the Yarrow water-tube boiler type. The Dutch boilers are, with very minor exceptions, practically the same as in the Austrian torpedo boat Viper, in which boat there are two boilers. The boiler arrangement is particularly interesting, as it is the first important case in which two classes of boilers are combined, and we have very good reason to believe that this will be repeated in other vessels. We are enabled to add a detailed drawing, which is of considerable interest. The general construction of the Yarrow boiler with its straight tubes is, of course, well known, but our engraving shows the thickened tube plates and the arrangement of the grate and air casing. It is a noteworthy fact that thick as the tube plates are, they can be distorted in expanding the tubes, and that skill and experience are required on the part of those setting the tubes, who work first at one side, then at another, as the indications demand; subsequently there is no trouble.

As it is a matter of very great interest to the profession generally as to the manner in which tubes can be renewed in a straight tube boiler like this, we append the following remarks—As a rule, if a few tubes burst they are plugged up. This is a very simple operation, and a few tubes failing makes very little difference to the efficiency of the boilers, considering the large number of tubes which each boiler contains. If, however, it is desired to replace the tubes, this can be done with very much greater rapidity than is generally believed. Messrs. Yarrow can replace and expand a complete transverse row in from three to four hours. The manner in which this is done is as follows:—The tubes in front of the burst one are removed, which may be done in the reverse manner to the way in which new ones are replaced. The tube is first inserted into the first hole in the drum and passed upwards into it; it is then lowered into the first hole in the water chamber below; after this is done it is then passed up again into the next hole in the steam drum, then brought down again into the next hole in the lower tube-plate, the tube being zigzagged as it were, into the position required. There is not the slightest difficulty in carrying this out, and it can be done rapidly. The upper end of the tube is expanded in the usual way from the inside of the steam drum. The lower end can be expanded in the same manner if the water pocket is sufficiently large to admit of a boy working in its interior, but if the water pocket is too small for this to be carried out, the expander is placed opposite the tube and the mandril of the expander is driven round by means of a jointed bar inserted from the steam drum.







One feature in the boiler arrangement is that the air passes to the fire through openings fitted with light non-return valves which are attached to a diaphragm plate, which is fixed to the front of the boiler. Immediately there is pressure in the stokeholds the air passes through these valves round the entire casing of the boiler, and then underneath the bars to the furnace. By this means the coal bunkers, which generally surround the boiler, are kept comparatively cool; and what is a much greater advantage, the hinged doors, from their position, are not likely to be distorted, while if these hinged doors are placed in front below the bars as previously done, they are very apt to get out of shape by the heat they are subjected to, and also by the accumulation of cinders preventing the doors from closing properly.

The advantage of straight tubes is self-evident, as they can be readily cleaned out and examined internally. It is a cheap form of construction, and the number of spare tubes required to be carried, as they are all straight, is much less than if they are curved to various forms. Boilers having straight tubes have now been in actual service for many years without any disadvantage being found through their adoption. The fact is the tubes are for all practical purposes, at the same temperature as the water, and are consequently of the same temperature as one another, therefore the difference through expansion—if there be any—is of such a trifling character as not to be beyond the limits of the elasticity of the material. This was clearly confirmed by Professor Watkinson's paper on water-tube boilers recently delivered at the Institution of Naval Architects.

LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

LIGHT RAILWAYS *v.* LIGHT ROAD LOCOMOTIVES.

Sir,—The following is written having particular regard to the probable effects upon the light road locomotive system of transport, consequent upon recent and future improvements in the construction and maintenance of country roads, and the possibilities incident upon repeals of the Road Locomotive Acts. It may be advisable at the outset to explain that my views are favourable to the use of light road locomotives in preference to light railways; but it is as well advisable to state that it is not intended to seek to claim general superiority of the former over the latter, but rather to advocate an extension of transport by light road engines under conditions favourable to their employment.

It is perhaps unfortunate for the pioneers of the "light railways panacea for the relief of distressed agriculture," that in many quarters too much by far is expected of it, and it may be taken for granted that the direct pecuniary relief to be gained by the distressed agriculturists from the laying down of light railways will be found—should the experiment be tried—in many cases rather theoretical than practical. Exponents of light railways should remember that at the present time, after over half a century's railway experience, one of the agriculturist's great grievances is that he is handicapped by high railway charges. To many it appears strange that a further commitment to railway enterprise, and that specially for agricultural produce purposes, should be so strongly advocated as a method of relief.

Now it is an admitted fact that road locomotive engines, in spite of the ridiculous restrictions imposed upon their use, have proved of very considerable service to the farming community in the matter of haulage of produce, manure, timber, &c.; and in considering this, special attention must be drawn to the fact that Acts of Parliament have not only restricted the employment of these engines, but have as a consequence restricted the manufacturers of them in the developement of design and construction, fitting them for up-to-date requirements. Added to these restrictions has been a not inconsiderable public prejudice, and, perhaps more important still, the undoubtedly bad condition of roads in rural districts.

It is in reference to this latter restriction that particular attention is drawn; it being almost unrecognised that in consequence of the results of the County Council and Parish Council Acts in the matter of an increased attention to road construction and maintenance, a condition of affairs is being produced that is certain to have a great influence on this question of the transport of agricultural produce from place to place.

The revolution effected in the construction and repair of macadam roads in towns and congested districts by the steam road roller is notorious; but it is little known that during the past two years in particular a most important innovation has taken place in rural districts—and is still developing—in this matter of improved roads; so much so, in fact, that the time is not far distant when our country roads will be in such a sound condition as would, a few years since have been thought not only improbable, but impossible. The value of steam road rollers was proved and settled a quarter of a century ago; but, owing to the peculiarities of our old system of rural district government, their use in country districts to any extent was hampered, and in fact almost impossible.

The new Acts have, however, by consolidating and grouping districts, and insisting upon a general system of public management, opened the way for improvements in road making, and these upon permanent and practical lines, with the result that during the past two to three years several hundreds of County and Rural District Councils have acquired steam road rollers of their own; very many more are hiring of other Councils or of contractors, and of the remainder it may be assumed that ere long they will have followed suit, rendering it more than probable that within a comparatively few years the whole of the main and ordinary traffic roads of this country will be in such an improved condition as will justify the opinion of interested observers that a great development of the road locomotive system of haulage on common roads is certain.

Another factor is at work hastening the consummation of this assumption, viz., the cordiality of the reception of the autocar, the commercial advent of which must mean such an alteration in the present Road Locomotive Acts as shall open up a very big field for the light, quick-running road engine, whether actuated by steam or any other motive power. In its present state the petroleum or electric motor-car does not seem to offer much scope for heavy traffic purposes, although it may be taken for granted that in this respect the future has many developments in store, and for practical purposes, as concerns the material subject in hand, steam engine makers of the standard type of road locomotive will probably very quickly take advantage of the licence a repeal of the Acts will allow, and produce engines which in such important points as speed, lightness, power, and economy, will mark an important departure from present practice, fulfilling the conditions required, viz., cheap and speedy transport.

In spite of the fact that Acts of Parliament make liable to a heavy fine the running of a steam engine upon the high road at a greater rate of speed than four miles per hour, there are at present working in this country a number of traction engines specially constructed for running at speeds up to seven miles per hour, and it may be assumed that, opportunities presenting themselves, these engines are frequently running at unlawful speeds.

In the early days of road locomotives there existed reasons for some of the restrictions imposed, the engines constructed thirty to forty years ago being at best cumbersome, noisy, and in many ways objectionable; but during the intervening period a number of improvements have been introduced, until the present day the traction engine is anything than the offensive object the early engine was regarded as. The principle of compounding has been adopted, economy in fuel consumption of 30 to 35 per cent. resulting; improvements in boiler construction have been continuous, with the same results; the spring difficulty has been practically solved, traction engines now being as well off in this respect as railway locomotives; noise in travelling has been much reduced; by the use of compound cylinders the objectionable beat of the exhaust steam is much reduced in intensity, and from being exhausted at a little above atmospheric temperature, is not nearly so perceptible as with single-cylinder high-pressure engines. Weight for weight, traction engines are much more powerful now than formerly. They are *recognised* "necessary evils," and as a proof of their success in the face of opposition, the fact of there being between 6000 and 7000 working in the British Isles is strong evidence.

An argument in their favour—and it is a strong one—is that traction engine development has been effected not only without the assistance of legislation, but in the direct face of its opposition, proving that these engines have been successfully meeting a practical demand, and meeting it to the advantage of both owners and employers. The question then arises, given fair play by law, and that official and public recognition their success warrants, in addition the advantage of better roads for travelling on, is it not probable that an important development is possible for road haulage by steam?

Judging by what has been so far accomplished in the face of obstacles, this deduction seems assured, and the question then arises, Is it certain that the present transition period is an opportune one, and would it seem prudent at such a time for the sinking of large sums of money, public or otherwise, in the laying down and equipping of light railways, whose future success or failure would in the majority of cases be quite problematical?

Belgium is quoted as an instance of successful light railways. But Belgium is practically destitute of traction engines; Belgium is not an agricultural country in the strict sense of the term. Distances between centres of population and industry are small; and Belgium has had no education in the subject of steam haulage on common roads. Ireland is quoted as possessing instances of non-success in light railways; and for comparison with the requirements and possibilities of Great Britain I would prefer to take Irish experience, case for case, than that of Belgium. Consider the difference in capital expenditure between the cost of opening up a district with a light railway and that with road engines. The former means purchase of ground in many instances, and in all instances the laying down and equipping of permanent ways, the building of stations, wharves and sidings, the permanent employment of officials, and the sundry incidentals necessary to the conduct of a railway; and in addition the heavy expense attached to the purchase of rolling stock. The latter means absolutely no expense whatever in the matter of permanent way, land, buildings, &c., nor a penny's expense in the matter of officials. A striking difference, surely?

But then consider the difference as regards security for capital expenditure. In the event of the failure, from a commercial point of view, of a length or system of light railway—and it is certain that such could not continue to be conducted at a loss—what becomes of capital sunk? To a large extent it would be lost, and the second state of those wont to depend upon the line for the transport of their produce and material would be worse than the first. With road engines a fiasco would be impossible; and, more important still for the users or customers, the competition that would be certain to result would ensure low rates of carriage. In the event of business on a particular route not proving remunerative to a road engine contractor, he would simply remove his plant to a more satisfactory locality; and should the user be the owner—which would be found in the majority of cases—he would in all respects be better off in keeping his engine at work, it being, in the first place, a fact that steam haulage on roads can be accomplished at half the expense of horse and with nothing like the trouble, and, in the second place, he would escape the inconvenience resulting from the abandonment of an unsuccessful light railway.

The point arises: Would it be possible for road engine haulage to be accomplished at as low rates as light railways? It is impossible to answer this satisfactorily in detail, circumstances being so varied. Where a light railway could command sufficient traffic to enable it to convey at low rates, the railway rates would in all probability be lower than those of the road engine, particularly if the distances traversed were considerable, and in such cases light railways would be of undoubted utility and pecuniary assistance to users. But it is unlikely that these instances would prove more than the exceptions; and bearing in mind the opinion generally expressed and nearly as generally accepted, that much reasonable doubt is allowable as to the success of much of the light railway that might be laid down, it would seem, in view of the promising prospects of road traction due to the several causes enumerated, that the time present is not to be considered propitious for a wholesale embarking in light railway schemes. There are doubtless many localities and districts in which light railways may prudently be constructed, and that as quickly as possible, but in many of such cases it is more than likely that distressed agriculture will not be found in a chronic state, lessening correspondingly the need prompting the railway's construction from the "distressful" point of view. The greater probability is that in districts where agricultural distress is chronic or intense, the very conditions accounting for such distress will militate against the success of light railways, and the responsibility attached to the sinking of capital under such circumstances would be more than sufficient for the man of ordinary conscience. It is to be hoped that public money will not be hazarded without the most careful consideration of not only the claims for and requirements of particular localities, but of the practical principles of the schemes, having in view the possible development of other methods of transport more likely to command success.

It remains a fact, however, that in spite of what may be done in the matter of light railways, the road engine has "come to stay," and is on the eve of a further important development. As a feeder for railways it is unequalled by any other system of motive power extant. It can be used nearly anywhere where it is possible to use a horse, and can accomplish under many difficult conditions work where horse traction is impossible. Its two chief drawbacks so far have been:—(1) That owing to law restrictions as regards speed, heavy slow-running engines for heavy loads have resulted. (2) That owing to the bad state of the majority of country roads, these heavy engines and their heavy loads have been in many instances held responsible for road damage, bringing upon the shoulders of their owners liability for heavy penalties. The latter of these drawbacks is being rapidly removed, and of the former it may be assumed that we have almost reached the end.

The position will then be that with better roads and fewer restrictions of the law, what is now being accomplished by road engines is as little compared with what will be possible under these altered conditions; it being recognised that the cost of transporting one load of, say, twenty tons, twelve miles in four hours, could be effected in two journeys, with half the weight, at double the speed, for at least no extra cost. But then an advantage would be that, whereas it does not pay to run heavy engines with light loads, thereby restricting their use, the light, quick-speed engine will be equally economical with light loads as the present engine is with heavy ones. That is to say, the light, fast engines will step in and deal with the light traffic heavy engines could not be profitably employed in; whilst, at the same time, by reason of their increased speed, they will be able to transport, when required, the same weight in the same time as the heavy engine, except in cases where bulk could not be divided, when the more powerful engine will still be employed.

There is another point worth notice in connection with this comparison of traction engines with light railways. It is impossible for the latter to reach the door of every customer; and except in the few cases where lines might pass or run through farms, produce and material will have to be transported to and from the line, incurring the expense of an additional loading and unloading when gauges might be different. With the traction engine the material can be loaded directly from the field, barn, or railway station, and conveyed to its destination without further handling; and it would be found in practice that, except in long distances, it would often cost as much to convey to the light railway as to the main line.

There is, of course, the question of capital, and it would be asked, Is there in rural districts the capital with which to develope this traction engine haulage system? From my own experience it can be assumed that to a very considerable extent private capital would be forthcoming for a further development upon paying lines, as indicated; but it can nevertheless be advocated that there would be good reasons for financial assistance in some public form, and that, too, with infinitesimal risk, should it be publicly and officially recognised that there is that sterling merit in the business by which the distinct probability of pecuniary advantage to agriculture could be anticipated. One advantage of immense importance possessed by the road haulage system is that to test its value for a locality no large initial outlay is necessary, as would be the case with a light railway. In fact, past experience has been that opportunities and demand have led to the development of road haulage, the one being automatic with the other. It has been a practical, profit-bearing business all through, and it is this that should make it worth the serious consideration of legislators and public men interested in this question of practical relief for agriculture.

It will be gathered from remarks in the foregoing that I do not put forward this road engine haulage system in direct antagonism to light railways. I have remarked that in many favoured localities the latter could well be laid down and profitably worked; and whilst my personal convictions on the subject are stronger than I have in this article given expression to, I admit and recognise that it would be almost as foolish to claim general suitability for road engine haulage as it is to advance the same claim for light railways. But from over twenty years' experience with business closely allied to that of agricultural haulage, and from having for a number of years made almost daily use of the oldest piece of open road light railway in the country, I have acquired the conviction that for the purpose in question the light, quick-speed road engine is capable of more general utility and benefit to agriculture than a wholesale system of light railways, having in view that the results attending unremunerative or lost capital, public or private, sunk in light railways, must in the end be felt by the public.

Slow Speed.

Maidstone, March 24th.

PERMANENT WAY.

Sir,—I pretend to something more than a mere practical knowledge of the above-mentioned matters, acquired during a series of years' service with the late Thomas Brassey, as "agent" entrusted with the construction of railways; and it is just possible, especially at the present moment, that a few words upon this very important matter may not be taken amiss by your readers—may possibly even be of use.

Whilst the locomotive has ever been the subject of consideration, to the last nut and rivet employed in its construction, or the endeavour to get the last unit of heat out of the fuel used, and every other department of railway manipulation—with one exception—has gone with the times, and has been subject to close practical and scientific investigation, that of the permanent way and platelaying—repairing—exist to-day just as when the department was handed over to the tender mercies of the navvy fifty years ago, a matter of "rule of thumb."

The great margin of safety which undoubtedly once existed between a tolerably well-bedded road, and the load rolling over it, does not exist to-day. Engines of four times earlier weights, and speeds of running at least double, constitute a coefficient of danger eight times, if not sixty-four times, what had once to be provided for. This is not accomplished now, with sleepers poised in the air upon not much more than 2ft.—certainly not 3ft.—super of surface of "packed" ballast, with all the rest of the sleeper in mid-air—"shovel packing" to the contrary notwithstanding—exactly as obtained fifty years ago, and under precisely the same kind of intelligences.

A body representing 90 tons, rolling down an incline of 1 in 200 at something like a speed of sixty to seventy miles an hour, would easily shift or "slew" a new road dangerously out of line, especially if it were not fully ballasted, and it had been subject to a soaking downpour of rain just before.

To be on the safe side in such an important work, something more should be required than the tap which the navvy gives with his beater on the sleeper when he moves away to "beat up" the next one; for dangerous forces have, with the time, come into play, far beyond what such a man or his ganger can appreciate, and which need all the intelligence of the professional man as well.

A new era of platelaying and maintenance will be inaugurated the day that a sufficient number of accidents have occurred to demonstrate the danger attending the present unconsidered and old-fashioned system, and, with all humility, I forward you these few lines in the hope that they may arouse the attention of the most interested in the business, and lead them to attempt the removal of one serious danger in railway travelling.

J. W. Wilkins.

15, Lilford-road, Coldharbour-lane, S.E.

(*For continuation of Letters see page* 354.)

King's College Engineering Society.—At a meeting of this Society, held on Friday last, a paper was read by S. L. Fletcher, entitled, "The Planets: Are they Worlds like Ours?" Reference was made to the doctrine of Copernicus that the earth was itself a planet, revolving around the sun, and turning upon its axis in the same direction as the other planets. In fact, the earth was so truly a planet, from the astronomer's point of view, that it was natural to inquire whether the planets were worlds, and whether life was likely to exist upon them. The planets naturally fell into two groups—the four small planets, including the earth, whose orbits lay within the ring of asteroids, and the four great planets, all situated further from the sun. The small planets were solid bodies, as shown by their densities, and revolved on their axes in about the same time as the earth; the large ones had low densities, and appeared to be in a heated and vaporous condition. The large planets were all attended by satellites varying from one to eight in number, and on these, warmed and lighted to some extent by the neighbouring bodies of their primaries, life might exist; though it could hardly exist at the present time on the giant planets themselves.

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Fleet-Engineers: John T. H. Denny, to the Trafalgar, additional, and for recommission; and Henry J. J. G. Moon, to the Thunderer; and Elijah Tucker, to the Colossus. Staff-Engineer: Henry J. Walker, to the Victory, additional, for the Boadicea. Chief Engineers: Edward R. Odam, to the Fox; and John G. Stevens, to the Nelson; and William F. Turner, to the Victory, additional, for the Mercury; Robert S. G. Norgate, to the Victory, for the Nymphe; Stephen Hockey, to the Sphinx. Engineers: Victor de Paris, to the Victory, additional, and afterwards to the Fox; Edward Chisman, to the Empress of India; and Herbert J. Little, to the Trafalgar, additional, for the Nelson; Ernest C. Thornhill, to the Redbreast; and Henry R. Teed, to the Pembroke, additional, for the Jaseur. Assistant Engineers: John L. Kimber to the Victory, additional, and afterwards to the Fox; Arthur Oliver, to the Resolution; Llewellyn Howell, to the Magnificent; and Gordon Robertson, to the Majestic; Thomas T. Brown, to the Trafalgar, additional, for the Nelson; and William Rattey, to the Nelson; and Edgar C. Smith, Henry R. S. Hughes, and Hugh L. M. Ford, to the Trafalgar, when recommissioned.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

R. J. G.—(1) *You can obtain full particulars from the Marine Department, Board of Trade, Whitehall.* (2) *You would be eligible for entry as an engineer student. Write to the Admiralty, Whitehall, for particulars.*

G. G.—(1) *It is used in various ways, and has no fixed value. If you will refer us to an example we will tell you the meaning.* (2) *Address Mr. Scott, care of the Secretary, Physical Society, South Kensington.* (3) *There is a number of books published by which you can teach yourself mechanical drawing. Messrs. Spon or Messrs. Lockwood will supply you with a list on application.*

S. H. M. (Commercial-road.)—(1) *There is no engineers' guide-book of the kind you want. It is not easy to see how one that was not misleading could be produced, seeing that the methods of production and cost of materials and labour vary in every district—see an article on estimating in our issue for March 13th, page 256, and that on wages in this issue.* (2) *You cannot harden soft steel or ingot iron without the aid of some carbonising agent, such as prussiate of potash or bone charcoal.*

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. *£0 14s. 6d.*
Yearly (including two double numbers) .. .. *£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. *£0 18s. 0d.*
Yearly .. .. *£1 16s. 0d.*
THICK PAPER COPIES—
Half-yearly .. .. *£1 0s. 3d.*
Yearly .. .. *£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS.—Wednesday, April 8th, at 2.30 p.m. To inspect the works of the Waterloo and City Railway.

GEOLOGISTS' ASSOCIATION.—Friday, April 10th, at 8 p.m. Demonstration, illustrated by the lantern, of Photographs taken on recent excursions of the Association, by Messrs. W. F. Gwinnell, F.G.S., and H Preston, F.G.S.

THE ENGINEER.

APRIL 3, 1896.

CIRCULATION IN WATER-TUBE BOILERS.

PROFESSOR WATKINSON'S paper, which will be found in another place, is a valuable contribution to the literature of an obscure subject, every point of which has been made matter of debate and controversy. How and why circulation is brought about, not only in water-tube, but in all other forms of boiler, is in no way obvious to those who are satisfied to think for themselves. At every step we take to an explanation of the phenomena we encounter difficulties and perplexities, contradictions and objections. It is not worth while to deal particularly with ordinary boilers, although on the circulation or want of circulation within them depends their success or failure when forced. We shall confine ourselves just now to the water-tube boiler. Professor Watkinson gave a very lucid statement of his theory of circulation. With that explanation we cordially agree. It would be remarkable if we did not, seeing that it is almost word for word the explanation that we have more than once advanced. To this explanation Professor Lambert takes exception. He says it is not true, and puts forward another. Professor Lambert's theory is that of many engineers. It is none the less unsound. Let us see what it is.

Taking the familiar illustration of a U tube, down one leg of which water descends, while up the other, heated by a suitable flame, steam and water rise, Professor Lambert asserts that the descent of the "solid" water results from the fact that the contents of the rising leg of the tube are less dense—in a word, lighter than the contents of the descending leg, or downcomer. There is a want of scientific precision about this statement, but we are not responsible for that. We must endeavour to find out what the statement means. The contents of the rising leg are water and bubbles of steam. Now Professor Lambert cannot possibly mean that the water in the riser is less dense than the water in the downcomer. What he does mean is, that the column of water containing bubbles of steam weighs less than the column of water without the bubbles, and is overbalanced by the downcomer, and so circulation is set up. But this bald statement will not suffice, for the simple reason that the weight of steam and water together in the rising leg may greatly exceed the weight of solid water in the descending leg, and yet rapid circulation will take place. In the Yarrow and Thornycroft boilers, for example, the weight of water and steam in the numerous risers very greatly exceeds the weight of solid water in the downcomers; yet circulation goes on, and this, too, although steam is actually made in the downcomers and bubbles are present in them. It is clear, therefore, that inasmuch as 5 lb. or 6 lb. of water in a downcomer can cause circulation, although opposed to 50 or 60 lb. of water in the risers, it is not mere relative weight that can bring it about. Let us suppose, indeed, that the water and steam are intimately mixed, and still the weight of the mixture in a number of tubes may be greater than that in a single downcomer. It is clear, therefore, that Professor Lambert, who doubtless knows all this, has something else in his mind. The moment, however, that the notion that mere difference of weight in the contents of the two tubes is the cause of circulation is abandoned, then the explanation which we have advanced, and which is accepted by Professor Watkinson, becomes the only explanation that is satisfactory. At the lowest point in the U tube we may conceive of the existence of a plane of demarcation dividing the water in the right leg from that in the left leg; we may imagine a diaphragm placed here across the tube. It is obvious that no movement of the water can take place down the right leg, let us say, so long as the *pressure* against the diaphragm due to the left leg is equal per square inch to the pressure of the water trying to descend. Now, so long as there is a column of water, no matter how thin or how light, extending from the top of the riser to the diaphragm, no movement can take place; the hydrostatic pressure being the same at both sides of the diaphragm. Of course it will be seen that the diaphragm is not in any way necessary. We suppose its existence merely to make our meaning clear. The contents of the riser may be broken up and ragged to any extent. There may not be half or a quarter of a tube full. So long as a column of water extends from top to bottom, so long will the water in the downcomer remain there. If it descends, it is not because of the fact that it weighs more than the contents of the riser, but for other reasons altogether. Neither Professor Lambert, nor any one else, has, so far as we are aware, attempted to prove that this argument is unsound. He will willingly admit, no doubt, that if a glass rod were put down the rising leg it would not cause the descent of the water in the downcomer, and he will not dispute that one riser, an inch in diameter, would balance the contents of a thousand downcomers of the same diameter. Thus, then, the controversy between himself and Professor Watkinson reduces itself to the assertion that such a column of unbroken water does not exist in a riser. On this point it is necessary to read carefully what Professor Watkinson has said. We assert that such columns always exist in the riser, unless the bubbles are sufficiently large to plug the tube; that is to say, to fill its whole diameter, as shown in Fig. 4 of Professor Watkinson's paper. But it is obvious that this plug action simply means cutting so much out of the hydrostatic column, and conditions may exist when a boiler is forced, under which an accumulation of foam takes place in the upper portion of the tube. The vertical length of the column producing hydrostatic pressure is correspondingly diminished, and a very violent circulation may result. But all this has nothing to do with Professor Lambert's views. He and many others with him hold that, under any and all circumstances, the presence of even a few bubbles in a tube is sufficient to produce circulation, because the water with bubbles weighs less than the water without them. It may be worth while to add one word here on the subject of entraining. Professor Lambert will have none of it. There is no such thing. Engineers would be only too happy if this were true, for then there would be no priming.

We may now proceed to inquire why bubbles of steam rise. The rising is often confounded with circulation; but, as a matter of fact, there is no very close connection between the two, and a water-tube boiler may get on very well without any circulation of water within the tubes. Thus, one speaker during the discussion at the Institution of Naval Architects, told the meeting that he had found the Niclausse boiler in a steam launch do just as well without as with the internal circulating tubes. We ourselves know of a large Field vertical boiler which worked successfully for more than twenty years without any internal or "Field" circulators whatever. The reason why a bubble rises is that it is pushed up. The pressure below it is greater than the pressure above it, and so it goes to to the top; and it will go to the top in a single tube so long as it does not fill the tube, and it will rise because water descends past it, between the sides of the bubble and the sides of the tube, and so circulation takes place under conditions which are certainly not those set forth by Professor Lambert. If the bubble quite fills the tube then there can be no movement. This can easily be proved by a very simple experiment with air bubbles in a small glass pipe. Now we may have conditions in which the bubble very nearly fills one leg of a U tube, but not quite. In that case it is pushed up from below, and it would rise, the water descending down the side of the tube. But water will take the line of least resistance, and inasmuch as it is easier to come down the open downcomer than it is to pass down round the sides of the bubble, it will take the downcomer as well as the sides of the riser, and the quantity descending in each tube will be as the areas open for the passage of the water, and so circulation will be produced. The downcomer and the riser may be regarded as one vessel for the time being. When the number of bubbles is so great that they quite fill the top of the riser with foam, the hydrostatic column is shortened by so much, and the circulation is correspondingly violent; and this is no doubt what occurs in nearly, if not all, water-tube boilers when pressed. It would be superfluous to reproduce here what Professor Watkinson has said on this point elsewhere.

We believe that we have now put this interesting subject into such a form that the issues are narrowed to the simple question—Does or does not a hydrostatic head exist at the base of the riser of a water-tube boiler? If not, what has become of it? We have shown that when the boiler is so pressed that the upper portions of the tube contain only foam, the hydrostatic head is reduced by the length of the foam column, and that in no possible case can the mere weight of water in the riser or downcomer have anything to do with the matter. The agent causing the flow or circulation of water is just the same as that causing the flow of water through any other system of pipes, and the laws of hydraulics operate without consideration for the circumstance that in one case the water may be hot, in another it may be cold. It is now for Professor Lambert, and those who hold his opinions, to find and point out the flaws in our reasoning and the inaccuracies of our statements.

INCANDESCENT GAS LIGHTING.

FOR many years attempts have been made, not without partial success, to convert a larger proportion of the total energy represented by the combustion of coal gas into light than is the case with ordinary burners, however good. The theory now generally received concerning the conversion of energy of combustion into vibrations of a wave length sufficiently short to be appreciable to the human eye as light, is to the effect that particles of carbon both solid and refractory are raised to incandescence at the high temperature engendered by the combination of the chief constituents of coal gas with the oxygen of the air. The nature and mode of translation of the bodies immediately concerned in the production of these solid refractory particles, and in their conversion into centres of radiant energy of short wave length, are still a matter of much controversy, pursued indeed by some of the combatants with a vigour bordering upon animosity. When the trifling percentage of the total energy of the combustion of coal gas which appears as light is considered, it is not surprising that means for increasing the output should have been earnestly sought, and that refractory particles less transient than those evolved by the action of combustion should have been tried as a medium for this conversion. The old Bude light, which exists to this day in the form of the lime light—still preferred for theatrical purposes over the light given by an arc lamp—is an instance of the kind, inasmuch as in that case the luminosity to be obtained by the consumption of gas with a normal quantity and pressure of air is sacrificed voluntarily, in order to attain a temperature high enough to raise a typically refractory substance, viz., lime, to incandescence. The obstacle to the general adoption of some such material thus heated arises from the fact that for the consumption of the gas in a manner capable of producing the requisitely high temperature a blast of air is indispensable. The prospect of supplying public and private burners with air under pressure is enough to make all but the boldest shrink. It could be done, of course—but the price? Consciously or unconsciously, inventors have gone at once to the root of the matter, and have sought a better refractory material—one which should be capable of yielding a fair output of light without needing special precautions for the raising of its temperature greatly above that attainable by a non-blast burner. Magnesia was tried in a variety of forms, one of the most efficient of which was probably that used in the Fahnehjelm burner, an apparatus consisting of a comb of magnesia rods suspended over a Bunsen burner and heated by the flame issuing therefrom. Similarly, some ten years ago, zirconia—the oxide of the rare metal zirconium—had a considerable vogue among magic-lantern exhibitors as a substitute for lime. From these facts it is clear that the instinct of the inventor led him to the exploitation of the matter to be heated rather than to the improvement of means of heating it, and events have shown that his instinct was sound.

The light now familiar to us as the incandescent gas light *par excellence*, more properly known as the Welsbach, may be truly regarded as the heir of previous devices, in that the refractory substance chosen is greatly better than that used in earlier attempts, while the burner embodies no new principle. Without being tedious, we may perhaps be permitted to touch shortly on the essential points of the modern Welsbach light. The burner is of the Bunsen type, *i.e.*, air is mixed with the gas before combustion in such a manner and in such quantity that the flame is non-luminous. Further, this Bunsen burner is of the "solid flame" class, its characteristic being that the supply of air is so ample that the inner cone visible in an ordinary Bunsen flame is diminished in size and sharpened in outline, and the flame as a whole would be on the brink of "catching back" but for the provision of a gauze cap over the mouth of the burner. This form of burner is capable of giving the highest temperature which is attainable without the use of a blast, and depends somewhat for its efficiency on the pressure at which the gas is delivered, about 1in. of water being a minimum below which the pressure should not fall. The jet from which the gas issues in the Welsbach burner is central, but the upper end of the burner is annular, the flame thus issuing so as to heat the mantle—of which more anon—in an efficient manner. From the centre of the ring-shaped mouth of the burner rises a rod of steatite, having a forked upper end adapted to carry a refractory mantle by a cross thread at the top of the latter. The mantle is thus hung in the flame from a single point of support. A chimney is used both to protect the mantle, from disintegration by chance draughts, and to ensure that the flame shall be caused to heat it uniformly. This chimney is generally provided with a choke, which, however, has no discernible influence on the efficiency of the burner, and may be conveniently reversed in position by turning the chimney upside down. Continuing a discussion of the mechanical arrangements, it may be said that most burners are provided with a bye-pass, so that they may be lighted without the use of a match, and with the avoidance of any slight explosion such as generally follows the lighting of a gas lamp having a chimney. Shock to the mantle on lighting is thereby mitigated. The bye-pass is a thing of dread; it has two adjusting screws, and conduces to profanity on the part of the regulator. One cardinal rule in the use of the burner should be observed: the cock proper to the burner should be turned full on, so as to shut off the bye-pass while the burner is alight, and regulation of the amount of gas supplied to the burner should be made by the cock on the common gas fitting, to which the burner is usually attached as a substitute for a plain jet. These matters are, however, not the kernel of the subject. Interest centres in the nature and properties of the refractory mantle. It must be premised that much which is known is not published, and many things published are much better unknown. The following description will nevertheless elucidate the principles concerned. There is a group of bodies of the same chemical class as aluminium, which includes the metals of what are termed "the rare earths." For the purpose of the present exposition they may be distinguished as substances forming oxides, viz., the rare earths themselves, which are exceptionally refractory and infusible. Their chief sources are certain minerals, formerly supposed to be extremely rare, and now found in fair abundance in Norway, Carolina, and other unconnected spots, known as thorite, orangite, monazite, æschynite, euxinite, and by similar esoteric terms. It is the oxides, fairly pure as regards common forms of matter, *e.g.*, silica, but judiciously blended among themselves, which constitute the material of which the mantles are composed. Thoria—the oxide of the metal thorium—is the chief constituent, its quantity amounting to 60 to 70 per cent.; the balance may consist of such bodies as terbia, yttria, and ceria. In the manufacture of the mantles the pure earths are first laboriously isolated from the cacophonously-named minerals containing them, and are then converted into nitrates by solution in nitric acid. The nitrates are chosen in preference to other salts, because they are freely soluble, and readily break up on heating, with the regeneration of the oxides. The substratum of the mantle is the best procurable cotton fabric, as nearly free as may be from ash; the reason for this freedom will be apparent later. The fabric is dipped in a solution or paste of the nitrates of the earths mentioned above, dried and ignited in a muffle until the organic matter of the fabric is burnt off, and the nitrates are decomposed, leaving a skeleton of the pure earths. This is much too fragile for transport, and is accordingly strengthened by treatment with a stiffening agent, the rationale of the operation being not dissimilar to that of domestic starching. The stiffening substance is of organic matter and free from ash, so that on first using the mantle it is burnt off, and the fragile skeleton of pure oxides is left once more. The operose character of the whole process is shown by the fact that whereas the cost of the raw material for one mantle—in the ore—may be taken as less than 1d., the manufacturing cost of the finished mantle is 8d. to 10d. The mantle thus made remains efficient until finally relegated to the dustbin. A passing word of pity for the fate of these rare earths, naturally shy and segregated, may possibly be permitted. The fate of these exclusive molecules, jostled by vulgar silica, and crowded by their poor relation alumina, is truly deplorable; moreover, it is not without practical inconvenience, for should failure of the present supply occur and the demand continue, the ruthless dissemination now taking place will indeed be regretted, but it cannot be repaired. A good mantle made in this manner gives a duty from gas much higher than can be attained by any other known means. Thus, a good governor burner, automatically lowering the gas pressure at the exit slit and burning 5 cubic feet per hour, will give about 15-candle power; 3¼ cubic feet of gas if burned in a Welsbach light will give 50 to 60-candle power when the mantle is new, and 40-candle power after 1000 hours' use. It must be remembered that but few mantles in use, even for domestic lighting, have a life of 1000 hours; the average is perhaps about half that period of time. The conditions which are essential for long life are, that the burner should not be on a swinging bracket, that it should be adjusted so that its axis is vertical—not often the case if a common gas fitting is used without correction—and that it should be protected from draughts and vibration.

The reason for the great light-emitting power of a mantle of those rare earths has been much debated. There are those who believe that the material has some specific property whereby it is capable of converting vibrations of large wave length—heat vibrations—into those of short wave length — light vibrations — and certainly the astonishing brilliancy of the rare earths compared with substances considered equally refractory, *e.g.*, alumina, gives some support to this view. The tendency of the results of such experiments as have lately been made is, nevertheless, in a contrary direction. It does not appear that thoria and its congeners differ from other relatively infusible substances in their power of emitting light. It is with them as with better known bodies, a function of the temperature to which they are raised. Logically it follows that a thoria, or similar mantle must be raised to a higher temperature than would be one of alumina when heated by the same burner. Now, the mean temperature of a Bunsen flame is approximately known, and is not inordinately high; very fine platinum wire will just fuse in it—as it will in a common luminous flame—a fact which gives the temperature as a little above 1775 deg. Cent. = 3227 deg. Fah.—always supposing that the fusion is not due to the formation of a carbide. However this may be, the temperature is not so high as to lead to the expectation that vibrations of very short wave length would be emitted by a refractory solid body immersed in the flame. But although the *mean* temperature of the flame may be moderate, *locally* the temperature may be exceedingly high. Hence an extremely fine fibre of refractory material may be raised to a temperature at which it emits white light. Such fibres would, of course, be vastly finer than the coarse strands composing the mantle, and, compared with them, the hair-like platinum wire mentioned above as fusible in a Bunsen flame, would be thick and coarse. The probable reason for the superiority of the rare earths over other refractory materials is at once apparent; it may well be that their infusibility is such that their most tenuous particles scarcely sinter or agglomerate even at the high temperature reached by them, whereas corresponding particles of alumina may tend to aggregate, and form fibres or masses comparatively gross. When once aggregation has occurred, the light emitted is no longer that proper to the local temperature of particular groups of molecules in the flame, but depends on the mean temperature of the flame, which is moderate enough. The necessity for the exclusion from the material of the mantle of all impurities capable of acting as fluxes, and favouring the sintering together of the fine fibres on which the efficiency of the mantle appears to depend, becomes evident from these considerations.

A final word must be said as to the products of combustion of the incandescent gas burner. Statements made for trade purposes are commonly allowed a little latitude, and in this case that axiom may be borne in mind when considering advertisements. There is no reason to suppose that an incandescent gas burner, working normally with an adequate air supply, does not consume the gas used as nearly completely as does a good Bunsen burner or a good flat flame luminous burner. The difference in the amount of products of combustion is, therefore, simply that due to a smaller consumption of gas for a given candle-power. There is no ground for believing that the products are less objectionable in kind than with a common burner; that most noxious impurity, sulphur, duly appears as its ordinary product of combustion, sulphur dioxide, and is only less harmful because its total quantity is diminished *pari passu* with that of the gas. The same is true generally. But this is a very different thing from basing the statement of the improvement in light on an equal consumption of gas, and in the same breath giving the diminution in quantity of products in terms of an equal output of light. One cannot eat one's cake and have it.

◆◆◆

WAGES IN THE CLYDE SHIPBUILDING TRADE.

As might have been anticipated, the settlement of the protracted and deplorable wages dispute in the Clyde and Belfast engineering trade, and the granting of a rise without the necessity of a strike to the iron shipbuilders, were the signals for demands by other sections of artisans—blacksmiths, carpenters, joiners, &c. All these branches have happily now been satisfied by an amended offer of the employers, and there is at last peace, or as near an approximation to it as possible, in the entire circle of trades connected with the shipbuilding industry. As the result of a ballot of the Clyde and Belfast districts of the Associated and Amalgamated Societies of Carpenters and Joiners, these bodies, on the 27th ult., agreed, by a majority of 858, to accept ¼d. per hour advance, dating from March 20th, and a further advance of ¼d. per hour on July 17th next. The men originally asked an immediate advance of ½d. per hour, and were offered ¼d., which they refused. Their acceptance of the amended offer means that their wages are increased as at the 20th ult., from 7½d. to 7¾d., and on July 17th they will rise to 8d. per hour. As to the duration of this agreement, the employers insist on a period of six months from the date of the second increase. This being agreed to means that there will be no change in wages either way before February 17th, 1897, as after the expiry of agreement either side would have to give one month's notice of proposed change. The work on hand, and already booked, in many cases will occupy builders during the larger part of the intervening period, so that actual work and further contracts will now be proceeded with cheerfully. There is cause for satisfaction also in the arrangement which has just been come to—as the result of conference in Glasgow—between the engineering employers of the Clyde and the Amalgamated Society of Workmen, on the subject of sectional or single-shop disputes. It has been agreed to form a Standing Committee composed of an equal number of employers and employed to deal with disputes prior to any stoppage of work. Many minor difficulties in individual shops have cropped up since the settlement of the larger dispute, and these having become so serious a trouble, a conference, having the above happy outcome, was arranged. In future no sectional dispute can reach a critical stage without first coming before the Standing Committee—a fact which in itself should go far to obviate strikes in individual shops, if not to prevent the disaffection which culminates sometimes in a general crisis.

THE COKE GAS POSSIBILITIES OF THE STATES.

The Dominion Coal Company of Nova Scotia, which produces and sells in Canada about 1,000,000 tons of coal a year, has applied to the Massachusetts Legislature for power to produce coke-oven gas at Boston, and to pump it through pipes to various parts of that State. The idea is to bring the raw coal from Cape Breton to Boston, erect a large central range of coke-ovens there, and then sell the resulting coke and tar and gas and ammonia. An Act is necessary, and the Committee on Manufactures has just heard evidence, the details of which have reached England since our last issue. The matter is more important than a mere commercial undertaking, because it virtually proposes to pipe coke-oven gas in the same way as natural gas, the supplies of which last illuminant and power producer are, as is well known, becoming short in the United States. The wholesale supply of coke-gas as a means of power and light would work an industrial revolution in the States if it were generally adopted; hence this first experiment in this direction is of great interest. The object of the promoters was explained by Mr. Henry M. Whitney, chairman of the Dominion Coal Company, who dwelt upon the desirability of locating the bye-product ovens near Boston, in the centre of a group of towns of over 500,000 people, where gas had a high commercial value. The inhabitants would, it is proposed, go to the expense of 1,500,000 dollars, or about £300,000, in laying down gas-holders and mains for the supply. The present consumption of gas in that group is 581,000,000 cubic feet, or 3,000,000,000 cubic feet short of a year's supply to Manchester in England—a city of 20,000 less people. The company aims at supplying this 3,000,000,000 cubic feet of coke oven gas. Either the inhabitants of the district or the promoters of the scheme would also have to put down plant for enriching the gas so as to give it adequate illuminating power. Mr. Joseph D. Weeks, of Pittsburgh, who has just completed his term as President of the American Institute of Mining Engineers, and who is a Government coke and gas expert, gave evidence in support of the scheme. He points out that natural gas is pumped 116 miles in some parts of the States, and coke oven gas could be treated in the same way. The highest coke production of the United States so far was in 1882, when it was 12,010,820 net tons, in the production of which 8,813,337 tons of coal were used. The official figures for 1895 are not yet issued, but they will be greater than these. Not one ounce of the valuable bye-products from these 18,000,000 tons of coal was saved. If we assume that 1 per cent. of sulphate of ammonia and 3 per cent. of tar are produced from each ton of coal coked, then it is clear—contended Mr. Weeks—that there were lost in the United States in that year 180,000 tons of sulphate of ammonia, which the land was crying for; 540,000 tons of tar—full of all the valuable coal-tar products, such as creosote oil, light oils, anthracene, and pitch—and in addition 10,000 times 18,000,000 cubic feet of gas, or in other words, 180,000,000,000 cubic feet of gas.

A QUARTER'S CLYDE SHIPBUILDING.

Clyde shipbuilding for the first quarter of the year—owing probably to the extra activity prevailing since the termination of the engineers' strike, and the retarding effect it had upon shipbuilding operations—has attained to record figures as regards tonnage output. Altogether, some 53 vessels of 98,700 tons have been sent off the stocks, this being the heaviest first quarter's tonnage ever put off the stocks of Clyde shipyards. The figures for March alone amount to 29 vessels of 40,700 tons. With the exception of March, 1891, and 1892, when 41,270 and 57,600 tons represented respectively the outputs, the present is the largest March output in the annals of the industry. As many as 11 of the vessels turned out during the period were over 3500 tons, and five were over 5000 tons. With the exception of the second-class cruiser Dido, of 5600 tons, all the work was for the mercantile marine. The total was made up of tonnage of the usual variety, large mail and passenger steamers, heavy deadweight carriers, swift river and channel passenger steamers, hopper dredges and barges, sailing vessels, and steam trawlers. As regards work on hand, this is estimated at somewhat over 300,000 gross tons. The total contracts booked since the year began aggregate about 100,000 tons, thus more than balancing the output, large as it has been. The bookings for March alone amount to over 45,000 tons, and several good contracts are known to be in the market, apart from the Government work still to be given out, in which the Clyde will probably share as usual.

LITERATURE.

A New View of the Origin of Dalton's Atomic Theory. A Contribution to Chemical History, together with Letters and Documents concerning the Life and Labours of John Dalton, now for the first time published from Manuscript in the possession of the Literary and Philosophical Society in Manchester. By HENRY E. ROSCOE and ARTHUR HARDEN. London: Macmillan and Co. 1896. Demy 8vo, pp. 191. 6s. net.

JUDGING from the fact that Sir Henry Roscoe has appended his name to two books on John Dalton within the last few months, it would seem that the chemical world is much perturbed concerning the origin of the atomic theory, and the object of the present volume is to set the matter all right, and incidentally to throw some light on the early days of present-day chemistry. The main point at issue is that it has hitherto been supposed that the atomic theory was the outcome of the experimental discovery of the law of combination in multiple proportions, whereas certain manuscripts and note-books of Dalton and others are taken to indicate that Dalton approached the atomic theory from a physical standpoint, and that this at once led him to conceive of chemical combinations as taking place between varying numbers of atoms of definite weight. The authors support the latter view, and ingeniously mould scarcely reconcilable data to bring conviction to the mind of the reader. The amount of success achieved in this directions will depend on the temperament and good nature of the latter, and whether he or she is sufficiently enthusiastic to weigh the conflicting statements with the perseverance displayed by the authors. One thing is very certain, that Dalton was endowed with a most fertile imagination, that was constantly at work suggesting consolatory explanations of tiresome problems arising from his investigations, that he thus propounded hypotheses, promulgated them, and frequently subsequently confirmed them, or even altered them, as his new knowledge dictated, and the atomic theory appears to have been one of these. Anyway, as the authors say at the end of the first chapter, to Dalton must be ascribed the rare merit of having, by the application of a single felicitous idea to a whole class of facts of chemistry, so completely comprehended the prevailing relations, that his generalisations have sustained without alteration the labours and changes of almost an entire century. The second chapter contains excerpts from Dalton's diaries—1802-1808—chronologically arranged. During the first four years his work was mainly physical, although there was some chemical work. In 1806 *et seq.* he did more chemical work, speculated about heat, &c. In the third chapter the various numbers suggested for atomic weights are set forth, with the considerations concerning them; whilst the fourth chapter is devoted to specimens of Dalton's lecture notes for lectures at the Royal Institution and elsewhere, the subjects being "On Heat," "Chemical Elements," "On Natural Philosophy, &c.," and "On Mechanics," and they form an interesting epitome of the views entertained on these matters eighty-five years ago. "Letters Written and Received by Dalton" is the title of the fifth chapter, and an insight is obtained into the reception of Dalton's views by chemists at home and abroad; into the work that was being done in those days, and the flounderings of the workers; and into the relations that existed between contemporary men of science. Here is an interesting example. Thomas C. Hope in 1811 writes to Dalton:—"I need not conceal from you that I am by no means a convert to your doctrine, and do not approve of putting the result of speculative reasoning as experiment. Still, however, I admire the ingenuity of your speculations, and the happy adjustment of its subordinate parts. It must be gratifying to you to see your doctrines adopted by the first names in the chemical world." In another letter Brewster refers to a proposed great meeting of scientific individuals in Great Britain, to be held at York on the 18th—25th July, 1831. This was the first meeting of the British Association. In conclusion, we may add that the work will provide instructive reading, more particularly for those interested in the rapid but gradual development of the science of chemistry; but to all who appreciate the progress of erudite thought and speculation its perusal can also be recommended.

Cinematica della Biella Piana. Per L'Ing. Lorenzo Allievi
Napoli. 1895.

ALL movements of articulated links in mechanism are reducible, as described in Kennedy's "Mechanics of Machinery," to what is technically called the three-bar motion; for instance, the beam, connecting-rod, and crank of a beam engine. The most complicated curves described by the different points of the parallel or valve motion of a steam engine are three bar motion curves. These curves are analytically of the sixth degree, and a most important discovery in their theory was made by Mr. Samuel Roberts, who showed that any such three-bar motion curve can be generated by three distinct arrangements of the mechanism. A very concise demonstration of this theory was given by Clifford in his "Kinematic." In Watt's parallel motion the head of the piston-rod is guided along one of these curves in the neighbourhood of a point of inflexion where the curve is straightest. For a long time it was supposed that an exact parallel motion, which should guide the head of the piston-rod in an exact straight line, was a mechanical impossibility; but the appearance of Peaucellier's parallel motion disproved this idea. Unfortunately, Peaucellier's motion did not make its appearance until parallel motion in steam engines was just going out of fashion, and the only place where it can be seen in active work is in the ventilating machinery of the House of Commons. Mr. Penrose, the architect of St. Paul's, has found that a modification of the Peaucellier cell will serve as a useful instrument for drawing the arcs and cutting the stones to circles of large radius, 200ft. or 300ft. Theoretically speaking, the Peaucellier cell and its modifications are the only mechanical means at our disposal for drawing an exact straight line; usually in geometry we copy a so-called straight edge when we carry out Euclid's instructions to draw a straight line; and however tight we may stretch a thread, we cannot pull it absolutely straight. Mr. Kempe's interesting little lecture, "How to Draw a Straight Line," will be found to be full of valuable criticisms and ideas on this subject.

The author of this book, L'Ing. Lorenzo Allievi, has made a collection of interesting and accurate drawings of all the most important cases that can arise in three bar motion. He starts with the well-known theorem that the relative motion of two planes in contact can be produced by rolling one curve fixed in one plane on another curve fixed in the other plane; these two curves are called the *centrodes*, by Clifford. At the point of contact of the two centrodes two equal circles are drawn, having the same tangent, and a diameter the reciprocal of which is the sum of the reciprocals of the radii of curvature of the centrodes; these circles afford simple geometrical methods of determining the curvature of any curve described by a point or swept out by a line which is carried round by the rolling centrode, the other centrode being taken as fixed. Carried points which lie on one of these circles—the circle of inflexions, *circolo dei flessi*—are passing through a point of inflexion on their paths; while carried lines envelope curves having cusps on the other circle——the circle of cusps, *circolo delle cuspidi.* In designing Watt's parallel motion, we draw the circle of inflexions of the centrode and place the carried point, the head of the piston-rod, on this circle. The amateur of mechanical movements, as well as the designer of working machinery, will find great pleasure and profit from a study of Signor Allievi's collection of diagrams; more especially if he will construct working models in accordance with the instructions given in Mr. Kempe's "How to Draw a Straight Line." Sheets of cardboard, or of zinc, will serve for the framework and moving parts; while the joints can be made rapidly and efficiently with the brass eyelet holes used by shoemakers, closed up by the bootmakers' pliers.

Sugar Machinery: A Descriptive Treatise devoted to the Machinery and Apparatus used in the Manufacture of Cane and Beet Sugar. By A. J. WALLIS TAYLOR, C.E. London: W. Rider and Son. 1896.

THERE is room for a comprehensive book on the subject which forms the title of this one. Mr. Wallis Taylor's book has made little difference. In his preface he speaks of the circumscribed limits permitted to a volume of moderate cost, and of his endeavour within those limits to provide as complete a compendium on the subject as possible. While, however, apparently sensible of the limitation as to space, he has filled a large number of his pages with matter which is not necessarily more appropriate in a book on sugar machinery than it would be in a book on brewing or brickmaking, or on steam engines, or boilers or pumps. For instance, there is no necessity for the author to go into a description on very inadequate grounds on what he considers the most suitable steam engine for sugar works; neither is it necessary that he should give a specification of a steam boiler which is neither complete nor brief; nor does the reason for occupying a lot of space with one kind of direct-acting pump when space necessary for relevant matter is absent, appear obvious. The same may be said of the room given to light railways and trucks, and to a large view of a centrifugal pump, or to much of the matter which is given in the appendix. There is, it must be admitted, a good deal in the book that is really relevant to sugar machinery or apparatus, but a great deal of the description is written in an involved style difficult to understand and incomplete in illustration. Examples of this are found on page 128 and many others. A description is given of the very elegant device of Mr. J. G. Hudson for an automatic pressure regulator for sugar mills, as made by the Mirrlees, Watson and Yaryan Company, and the description is more complete than that given of other apparatus, but the credit of the invention of the device is not given to Mr. Hudson. By revision and re-editing the book might be made much more useful than it is in the present edition.

SHORT NOTICES.

Physical Units, by Magnus Maclean, M.A., D. Sc., F.R.S.E. London: Biggs and Co. Price 2s. 6d.—This is in many respects a very useful book, more particularly to those who have to deal with facts, figures, and forces recorded and measured in C.G.S. units. The first chapters are on fundamental, geometrical, kinematic, dynamic, electric, magnetic, electrostatic, and electromagnetic systems of units, and these are followed by twenty-two tables relating to the physical properties of solids and gases, including modula of elasticity, moments of inertia, densities, molecular data for gases, specific conductivities and resistances, specific heats, boiling points, and so on. Amongst the tables there is one on indices of refraction of solids, liquids, and gases, in which several of the figures given are incorrect, and in the tables of specific heats of liquids and boiling points of latent heats of evaporation, the petroleums of which we so frequently want in these days to know, these values are not given. Useful as the book may be to those who are teaching physics, the use of metric and C.G.S. units limits its value to this field.

Griffin's Electrical Engineers' Price Book, for the use of Electrical, Civil, Marine, and Borough Engineers, Architects, Railway Contractors, Local Authorities, &c. &c. Edited by H. J. Dowsing. New edition, revised throughout and enlarged. London: Charles Griffin and Co., Ltd. 1896. Price 8s. 6d.—A price book like this provides with little trouble much of that information which can otherwise only be obtained from large numbers of catalogues. It provides, moreover, an index to the names of the makers of various machines and fittings, a selection of whose prices are given. A difficulty in preparing a price book lies in the necessity for selection among makers. The difficulty is in this case very well surmounted, but in the case of gas and oil engines the omissions are rather striking. The electrical apparatus, of which particulars, hints, and prices are given, are so numerous that every maker seems to be well represented. Beside the prices, the book contains a great deal of handbook information relating to statutory powers, and to each of the subjects of the thirteen chapters. These introductions to the chapters, and the hints with respect to the use and working of the materials, apparatus, and machinery dealt with, add considerable value to the book.

Light Railways for the United Kingdom, India, and the Colonies. A practical hand-book setting forth the principles on which light railways should be constructed, worked, and financed, and detailing the cost of construction, equipment, revenue, and working expenses of local railways already established in the above-mentioned countries, and in Belgium, France, Switzerland, &c. By John Chas. Mackay, F.G.S., A.M.I.C.E. Illustrated with photographic plates and other diagrams. London: Crosby Lockwood and Son, 1896. Price 15s.

YORKSHIRE COLLEGE ENGINEERING SOCIETY.

GAS ENGINES.

AT the meeting of this Society in the Yorkshire College on the 16th ult., Mr. Wm. Norris, M.I. Mech. E., gave a paper on "Gas Engines."

At the outset the author dwelt upon the early pioneering work of Messrs. Crossley Brothers in taking up the manufacture of the 1866 free piston type, which now appears so crude when compared with the celebrated 1876 pattern. In speaking of the further developments of the gas engine, Mr. Norris strongly deprecated the tendency to construct engines having a large bore and short strokes, which from a mechanical, and even a scientific, point of view is wrong. With regard to "self-starters," Mr. Norris thought their introduction was due to Messrs. Hamilton and Rollaston, who brought out the first hand pump starter, whereby a charge of gas and air is pumped into the cylinder. Illustrations were shown of Lanchester's low-pressure starter, and Clerk-Lanchester's high-pressure starter. The author then described the methods of governing gas engines adopted by Messrs. Robey and Co. on most engines. The application of Mr. J. Richardson's electric governor to a gas engine was described and illustrated. This consists, briefly, of a solenoid wound as a shunt from the main current, into which an iron core is drawn by the magnetic force. This movement actuates the pecker of the gas valve, and cuts out the supply as the speed rises. The "Scavenging Method" was well described and illustrated; results of tests with and without the scavenging method were given. Mr. Norris said there was little or nothing to be gained by using more than 95 lb. compression; in fact, very good results have been obtained by using a much less compression.

Dealing with the question of impulse every revolution, Mr. Norris said that in his opinion this cycle would ultimately take the place of the now almost universal Otto. The early Clerk and Robson engines were described, and though it was considered by some that the Clerk engine was obsolete, the author thought very good results might be obtained by modyifying the construction of the engine. The author then described his own "impulse-every-revolution" engine, which has been very favourably received. In this engine the exhaust products are discharged at the extreme end of the combustion chamber by a charge of pure air; the piston to be taken out at the front end without breaking any joints; the gas injected into the combustion chamber on the return or compression stroke, and the whole operation performed in one cylinder, with an ordinary crank and connecting-rod. The front end of the cylinder—unlike the Clerk and Otto engines—is closed, the motor piston having a rod and gas pump combined. There is a compression space as in other engines containing the exhaust valve and gas inlet from pump. The action is as follows:—During the return stroke air is drawn into the front end of the cylinder at atmospheric pressure through an automatic valve, and gas is also drawn into the small pump cylinder. The next outstroke compresses the air into an intermediate chamber—at about 4½ lb. per square inch above atmosphere—until the piston has travelled nine-tenths of the outward stroke. A port in the piston then opens communication with the air-port passage from an intermediate chamber, and remains open until the piston has travelled one-tenth of the inward stroke. The exhaust valve having already been opened before the piston has travelled nine-tenths of its outward stroke, and the exhaust column having been put in motion, the air in the receiver accelerates the products. In the meantime, the compressed charge of air has been transferred from the front end to the combustion chamber, and immediately the air and exhaust ports are closed the gas is tripped at a high pressure. The remaining nine-tenths of the inward stroke is available for compressing the gaseous mixture, which is fired by the ordinary incandescent tube when the piston has reached the end of its inward stroke.

Owing to free passages the power absorbed by gas and air pumps is, it is said, only about 1¾ indicated horse-power with an 8in. cylinder.

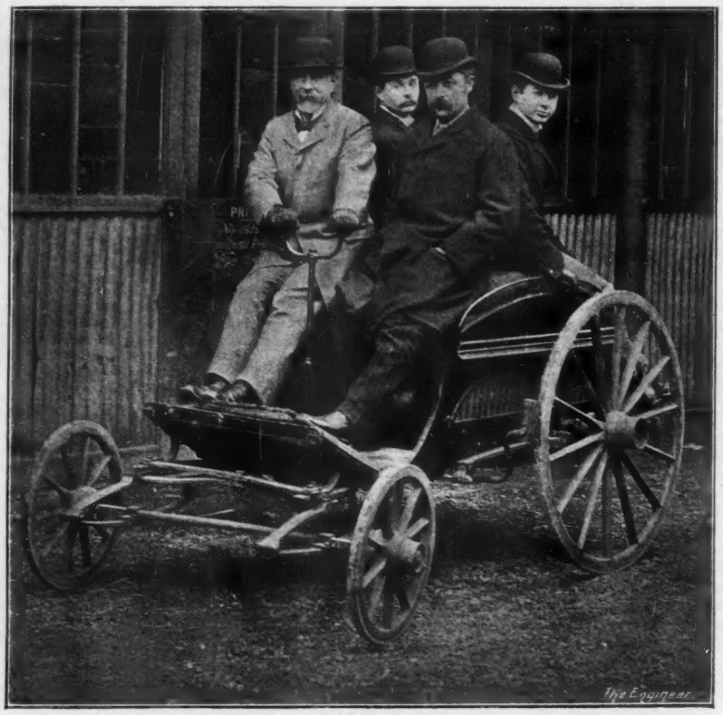
The governor is arranged so that when a cut-out is effected the gas is allowed to pass back to a small reservoir which is shut off from the gas main by means of an automatic valve. There is, therefore, no gas stored up at a high pressure. This engine is also made with a differential piston, having the same cycle of operations, though fitted with a double-acting air pump. The advantage gained by using a differential piston is, that when working up full power with large engines, a greater quantity of air is allowed to pass through the combustion chamber. Should, however, this engine be required at half-load, only one side of the differential piston need be used. The air inlet may be spragged; and the governor may be arranged to act on the suction valve at the back end of the differential piston with great advantage. The maximum pressure from explosion is said not to exceed 200 lb.

A RICHMOND paper announces that Mr. Arthur Peirce, son of Mr. Peirce, the borough waterworks engineer, has been appointed to the post of assistant engineer to the Calcutta Corporation out of seventy-seven candidates. Mr. A. Peirce, who will leave England shortly to take up his new post, has held an appointment in South Africa, and is at present engineering assistant to Mr. Gaskin, the chief engineer to the Nottingham Corporation.

SOME MORE HORSELESS CARRIAGES.

THE engravings on this page illustrate, and the following is a description of an experimental horseless carriage, constructed conjointly by Mr. G. B. Petter, engineer, and Messrs. Hill and Boll, carriage builders, Yeovil. It is driven by an oil motor, the cylinder of which is of cast iron, 3·5in. diameter and 6in. stroke, with light steel water jacket. It is bolted to two parallel steel bars, which carry the main bearings. The crank shaft is balanced, and has a bored recess for oil, of which it carries sufficient for a day's run. The first motion chain E E^1, Fig. 2, conveys power to the intermediate shaft H by means of a friction gear operated by a lever at G, Fig. 2, and A, Fig. 3. This lever, pressing by means of frictionless steel centres against the bell crank W, slightly moves the shaft, and grips the chain wheel E between the wood blocks F F F F. The same lever, pulled instead of pushed, puts on the brake V V, and thus forms in one, starting, stopping and brake lever. M, Fig. 2, and B, Fig. 3, is the lever for changing speed, and the slow speed wheel L has a ratchet box at R, which enables the axle to overrun when the high speed is in operation. T T, &c., are the carriage springs, and X X the axle bearings. The steering gear requires no explanation.

The water and oil tanks are at the rear immediately under the back seat. The total weight of the carriage, with oil and water complete, is 9 cwt., of which the engine proper, including fly-wheel and side bars, weighs 120 lb. Mr. Petter thinks considerable reduction can be made in the total weight without decreasing the strength of the engine. The carriage is intended for two persons, with which a speed of ten miles an hour is obtained on level road. It will mount the hills of the neighbourhood with two persons, but larger power would be used for four persons. The vehicle shown will carry four persons on level roads and small gradients as in the engraving, which shows Mr. James B. Petter, of the Nautilus Grate Works, steering; Mr. H. W. Southcombe, magistrate, of Yeovil; and Mr. G. B. and Mr. E. W. Petter.



The Engineer.

Fig. 1—PETTER AND HILL AND BOLL'S OIL-MOTOR CARRIAGE

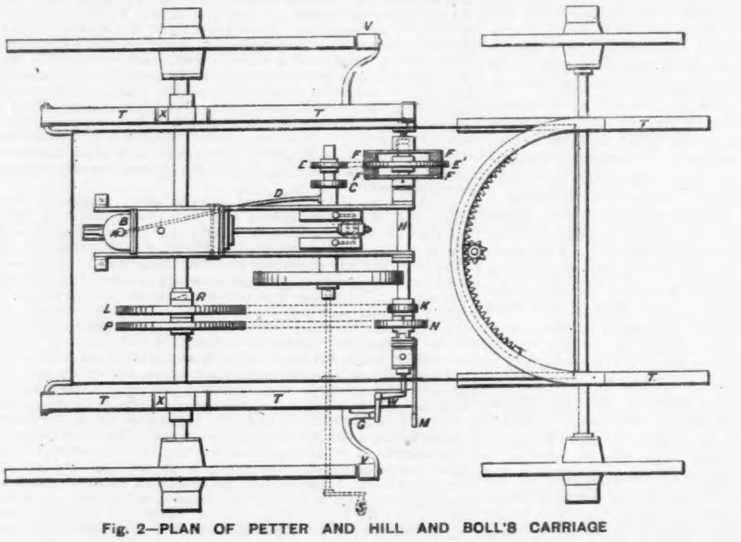


Fig. 2—PLAN OF PETTER AND HILL AND BOLL'S CARRIAGE

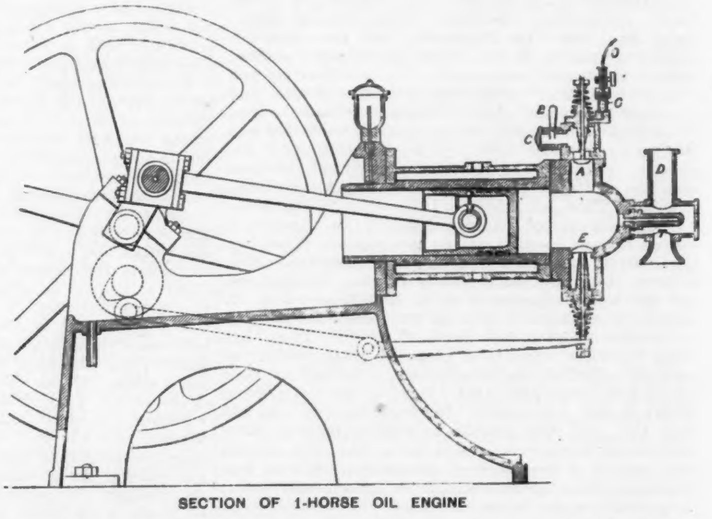

SECTION OF 1-HORSE OIL ENGINE

The exhaust is, we are informed, quite invisible, and the engine almost noiseless. The whole of the machinery is enclosed and completely out of sight, but can be easily reached for oiling, &c., by raising the back and seat covers. The levers are conveniently placed for the right-hand driver. A removable handle S is used for starting the engine in the first place, and an arrangement — not shown on plan — is made so that this handle when put in position automatically opens the exhaust valve, which closes instantly, when a good impulse having been given, the handle is withdrawn and the engine starts. The main road wheels are 42in. diameter.

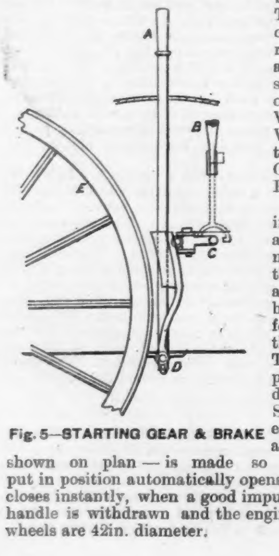

Fig. 5—STARTING GEAR & BRAKE

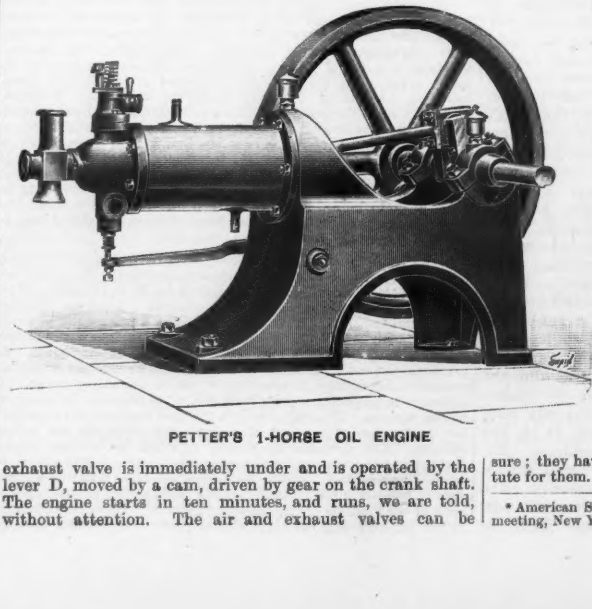
The 1-horse power oil engine used in the carriage is shown, as made in the form of a horizontal stationary oil engine, by the accompanying engravings, the principle of both engines being the same. As illustrated, however, it is mounted on a cast iron bed and has a heavier fly-wheel for stationary purposes. The oil gravitates to the combustion chamber, into which it enters through the air valve. The exhaust valve is opened by a lever operated by a cam driven by spur wheels from the crank shaft. Tube ignition is adopted, and a small heating lamp is used. The air valve A opens by the suction of the piston, and forms also the oil inlet to the combustion chamber B. The oil drops from an oil receiver through a glass tube to the top of the valve, where it spreads and is drawn in and broken up into spray by the entering air. The exhaust valve is immediately under and is operated by the lever D, moved by a cam, driven by gear on the crank shaft. The engine starts in ten minutes, and runs, we are told, without attention. The air and exhaust valves can be removed for cleaning when necessary, and replaced in two or three minutes without breaking any joints. The cylinder, vaporiser, and valves are shown by the sectional engraving.



PETTER'S 1-HORSE OIL ENGINE

SCREWED FITTINGS FOR HIGH PRESSURE.*

By HUGH J. BARRON.

ONE of the most remarkable things in the development of the use of iron pipe has been the standard fitting and standard thread, both of them depending primarily on the standardising of wrought iron pipe. When we come to think what the pipe industry would be without these standard articles, we begin to think it marvellous that they have been devised, and that an agreement in regard to standardising was reached so early in the development of the industry. Standard articles of every character tend tremendously to the cheapening of their production, and thus fill an economic necessity, but this very advantage has its drawbacks. With standard fittings the great difficulty to-day is that the refining process of cheapening production has gone so far as to call for a reaction in favour of special fittings for special work, and the purpose of this paper is to advocate the manufacture of wrought iron or wrought or cast steel or malleable iron fittings for screwed work for heavy pressures and for all large pipe work except that used for very low pressures. Forged fittings are so much more reliable, so much surer in every way, that it is strange efforts have not been made to displace the cast iron fittings. When the fittings that are now in use were designed, low pressures and small sizes of pipe were the rule. Within a few years the conditions have changed; high pressures are now the rule, and large sizes of pipe in connection with large power plants are no longer the exception. The changes that are required by modern conditions are confined to ells and tees and to sizes larger than 3in.; all other fittings, I believe, are safe and satisfactory, and the smaller sizes of tees and ells are not seriously objectionable, even at high pressures, but the ordinary 3in. ell or tee at 100 lb. pressure is decidedly dangerous, and the engineer who does not feel nervous when he is close to one of these fittings when there is water hammer and heavy pressure combined, must be very courageous or very reckless. When the various strains that such fittings are subjected to are considered, instead of the usual factor of safety of six being present, there is absolutely no factor of safety at all, or the factor is so slight as not to be worth considering; first there is the pressure, then there is the pressure or tension set up by the taper thread when it is jammed in by the fitter and the chain tongs—this is a constant strain tending to burst the fitting—then there is the shrinkage strain of the casting, slight of course, but must be considered as increasing the complexity of the tension on the fitting. To these add the strains due to the expansion of the pipes and the tremendous strains due to the blow a fitting receives when water jumps into a partial vacuum, and is it any wonder that fittings burst? Blow holes and imperfect castings add to the danger and unreliability of cast fittings; the marvellous thing is that there is not more trouble from this cause, but as pressures continue to go up this trouble will increase. None of the ordinary ells and tees above 4in. in size should be used for pressure above 50 lb.

These remarks do not apply to flanged cast fittings, and many get over the difficulty of the screwed cast fittings for power work by specifying and using flanged cast fittings and flanged cast pipe or wrought iron or steel pipe with cast flanges, but I am inclined to think that there is a better way of overcoming the difficulty; that is, either make cast screwed fittings for power work twice as heavy as they are made to-day, or substitute forged fittings or cast steel or malleable fittings. I am one of those who do not like flanged joints if they can be avoided, and I believe that, with the proper fittings, screwed joints are far more satisfactory. The question of pipe and fittings for high-pressure steam is outside the scope of this paper, but that there is room for improvement in ordinary power piping is evident by even a slight examination of any large plant. Engine builders some years ago, in order to get the initial pressure in their cylinders as close as possible to boiler pressure, advocated long sweep fittings, similar to hydraulic or hot water fittings. Some engine builders make patterns for these fittings that were extra heavy, and I think with a sufficient factor of safety, but I am inclined to believe that a forged wrought iron fitting would be the best, and to have the pipe work almost entirely wrought iron; that is, the fittings and even the valve bodies forged, would be the safest for high pressures. A possible solution of this problem may be in the gradual introduction of malleable steam fittings of heavy pattern for steam work. I have used such fittings for many years and have always found them satisfactory, but the larger sizes are entirely too light for present day pressures. If, in addition to the standard flanges which have been adopted by the trade, we had a standard ell and tee, it might possibly be a step in advance. I am averse to advocating special measures of this kind, as I am afraid they interfere with the natural development of the best device, or have a tendency to do so, but I do not believe any harm can be done by condemning the present cast fitting for high pressure; they have outlived their usefulness, and we need a substitute for them.

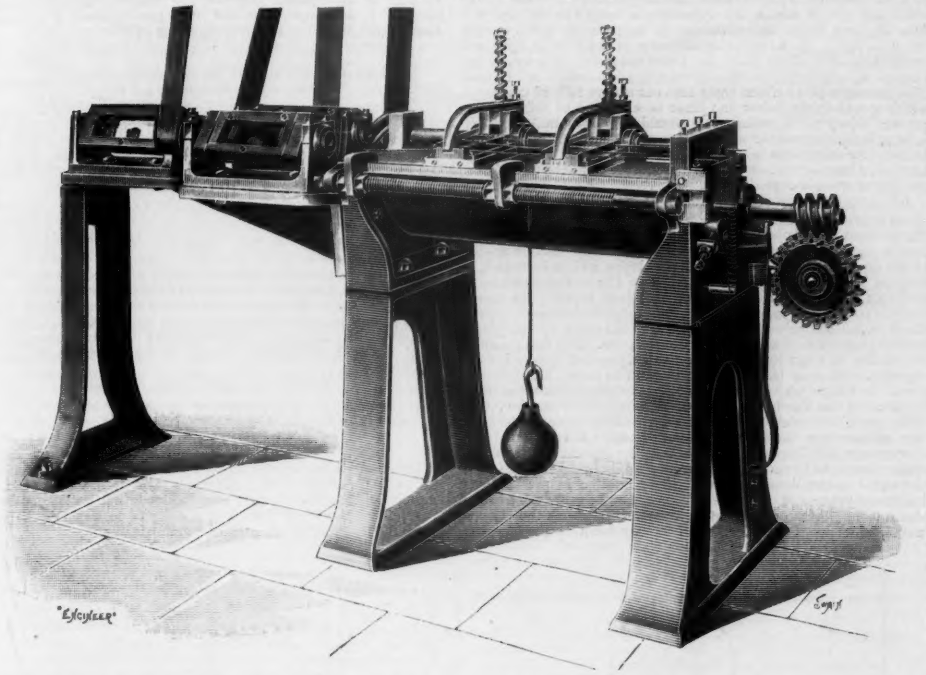
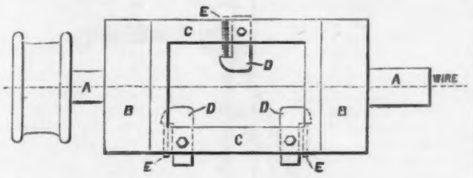
THREE-WIRE CUTTING AND STRAIGHTENING MACHINE

MESSRS. TAYLOR AND HATTERSLEY, BRIGHOUSE, ENGINEERS



THREE-WIRE CUTTING AND STRAIGHTENING MACHINE.

By the accompanying engravings we illustrate a three-wire cutting and straightening machine, designed to keep pace with the demand for cut wire of various lengths, more particularly as used in the cycle trades. The machine under notice will take a range of sizes from No. 7 S.W.G. to No. 14. The carriages with the nipping device are of new form and design. They are shown separately, and are so arranged that each wire receives exactly the same pressure, so that no slip can possibly take place when the tension is once adjusted. The carriages are moved forward by a cam, and drawn back by the weights shown hanging down. The cutting-off device is operated by a worm and wheel motion, into which are inserted pegs, thus avoiding the trouble and delay when change wheels are employed. The three revolving spinners, into which the brass or hard steel dies are inserted for straightening the wire, are arranged to be driven by one belt. This device, along with the cut-off motion and nipping arrangement, is the subject of a patent. The weight of the machine is about 14 cwt. Its output is equal to three single-wire machines, but we understand its price is little more than that of a first-class machine of the old sort. The revolving spinners are separately shown by the above diagram, in which A are the bearings; B is the body of casting; C is the loose piece bolted on to B; and D are the brass or hard steel dies set up by screws E. If the wire is stiff more tension is put on it by advancing the dies towards each other. These dies revolving round the wire at a speed of 2000 revolutions per minute, make it perfectly straight. The two carriages carrying the nipping dies working alternately, carry the wire forward to the cut-off dies, the motion of which is regulated by the worm and wheel device shown in illustration.



CIRCULATION IN WATER-TUBE BOILERS.*

By Professor W. H. Watkinson, Glasgow.

The main object of this paper is to draw attention to a series of models, which will be shown in action at the meeting, and which I have had constructed in order to show the nature of the circulation in the various types of water-tube boilers. The tubes in these models are of glass, ranging in internal diameter from $\frac{3}{8}$in. to $1\frac{1}{4}$in., and the drums are provided with glass ends, so that the whole of the action in the boilers can be observed. As there has been a great deal of discussion, and as inaccurate views are still prevalent regarding the causes of circulation in water-tube boilers, it will be well, before describing the action in the various models, to summarise the author's conclusions regarding this matter.

Causes of circulation.—"The causes of circulation in water-tube boilers are:—(1) The difference in density of the water due to difference in temperature when the fires are first lighted. This circulation is very sluggish. (2) When the water is all at approximately the same temperature, and steam is being generated, but not with sufficient rapidity to cause a break in the continuity of the water, a much more vigorous, but mainly local, circulation is set up by the entraining action of the bubbles of steam rising through the water. (3) When steam is generated with such rapidity, that in some part of the circuit there is steam or foam only present, a very rapid circulation takes place, due to the difference in density between this steam or foam and the continuous water in the downcomers, internal or external."† These conditions are illustrated by the annexed diagrams. In Fig. 1 steam is not being generated rapidly enough to completely fill any portion of the tube A with either steam or foam, and the continuity of the water in A being unbroken, the only cause of circulation, assuming the water to be all at the same temperature, is the entraining action of the bubbles rising through the water. By many the circulation, in this case, is said to be due to the difference between the density of the column of water in B, and the average density of the steam and water in A. That this is not so is shown by the experiment illustrated in Fig. 2, in which air is sent into the inner tube from a horizontal nozzle at C. When the top of the inner tube is above the water level the rise of level in the inner tube is very small, and when the conditions are as shown the circulation is comparatively sluggish. If the nozzle C, however, be turned upwards a much better circulation is induced, but the action in this case is not analogous to that in a boiler. Another way of regarding the matter is indicated in Fig. 3, where a series of beads are shown attached to a fine wire. When the beads are moved either upwards or downwards a circulation is set up due to their entraining action, exactly as in Fig. 1. The circulation, therefore, under the conditions shown in Fig. 1 is due solely to entraining action, and not to difference in density of the substance in the two legs. It is due really to the difference in density between the steam and water in the same leg, which sets up a relative flow of the two, and the entraining action of the rising bubbles causes the circulation round the circuit, as well as the local currents which are at the same time induced. In Fig. 4 steam is being generated more rapidly, and portions of the tube are filled with steam to the complete exclusion of water from these portions. In this case a rapid circulation takes place on account of the average density of the substance in A being less than that in B. This kind of circulation is by far the most thorough, as none of it is merely local. When working at atmospheric pressure, at rates exceeding about 2 lb. of steam per square foot of heating surface per hour, and with tubes $1\frac{1}{4}$in. in diameter, the bubbles do not fill up the whole diameter of the tube, as shown in Fig. 4, but the upper part of the tube becomes filled with foam to the complete exclusion of continuous water, as shown in Figs. 7, 8, and 10. The circulation in this case is, of course, due to the difference in density between the foam in tube A, and the corresponding column of water in tube B, Fig. 10. The circulation in this case is also vigorous, but, as a considerable amount of water falls down from the foam, it is more local, and not as thorough as in the last case.

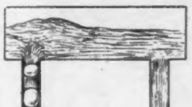

Fig. 4.

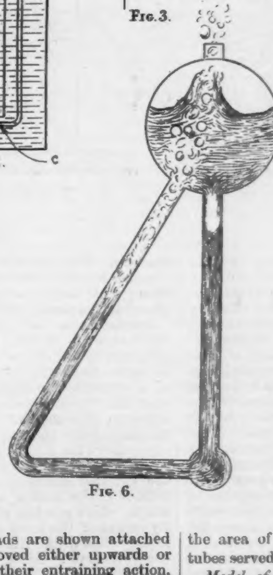

Fig. 6.

Description of Models.

Model of Belleville boiler (Fig. 5).—This consists of two elements, each containing twelve tubes of $\frac{11}{16}$in. internal diameter, joined in series. The distance between the centres of the end boxes is 2ft. 3in., and the inclination of the tubes is 4 per cent., as in actual boilers of this type. The action of the automatic non-return valve at A is very clearly shown. The normal level of the water is about that of the middle tube, but in starting, in order to prevent overheating of the upper tubes, it is necessary to have water in all the tubes. The action in the Belleville boiler is so different from that in any other boiler that it may be well to explain it somewhat fully. As is well known, this boiler consists of a number of elements connected in parallel between the feed distributing box—as I prefer to call it—and the steam drum. The total length of tube in each element is, roughly, 150ft., and, as the inclination is only 4 per cent., the upper end of this 150ft. of tubing is only 6ft. above that of the lower end, and the discharge into the drum takes place at about $1\frac{1}{2}$ft. above this. If each element consisted of one straight tube 150ft. long, instead of twenty tubes connected by end boxes, as in the actual boiler, the circulation would be of the same nature as that in other water-tube boilers, and a circulating force of, say, 1 lb. per square inch—assuming the head effective for circulation to be 2ft.—might be great enough to push the water through the tubes, in spite of their great length. Owing, however, to the abrupt changes in the direction of flow of the water which take place at each junction box, the total resistance to the flow is too great to allow sufficient circulation with this circulating force. To get over this difficulty the orifices through which the water flows from the feed distributing box to the elements are very contracted, and at the bottom of each of the two downcomers is an automatic non-return valve. With these arrangements the action of the boiler is similar to that in the old-fashioned Savery steam pump; the water is forced into the elements intermittently by the available head of about 2ft. instead of by the atmosphere, as in Savery's pump, the non-return valve and the contracted orifices serve as the suction valve, the steam is generated in the tubes themselves instead of in a separate boiler, and the necessity of a delivery valve is got rid of by discharging into the steam drum above the water-level. The action, therefore, is intermittent, and some water is driven backwards through the contracted orifices during the time plugs of water and steam are being pushed forward into the steam drum. The non-return valves prevent water being driven back through the downcomers into the steam drum. When warming up the action is intermittent, as in all cases where the discharge takes place above the water-level, but in this case there is a violent water-hammer action, owing to the form of the end boxes, and to steam being generated in several of the tubes at once. Steam generated in the lowest tube pushes the water up into the upper tubes; the steam formed in the upper tubes tries to push this water back again at the same time that it pushes the water in front of it forward into the upper drum; and on this account when first raising steam the shocks are often very violent. When properly in action the circulation is very vigorous and thorough, the alternating plugs of water and steam racing each other through the tubes of the element at a very high speed. The amount of water in the tubes is, however, very small, excepting in the lowest tube of each element, which contains much more than any of the others. The circulation in the lowest tube of the element is least thorough and is partly alternating.

Model of the Yarrow boiler (Fig. 6).—It will be observed that one half of this boiler is arranged with the tubes discharging below the water-level, as in actual boilers of this type, and the other half with tubes discharging above the water-level. An external downcomer is provided for each half, and a plug is provided so that the downcomer for the drowned tubes may be closed. Either half of the boiler may be used separately. (1) Action with the submerged tubes and with the downcomer shut off. As soon as the fires are lighted circulation commences, and when boiling first begins, plugs of steam and water are periodically projected into the upper drum, causing a considerable disturbance of the water level there. When the boiler is working at a high rate of evaporation the discharge from most of the tubes is practically continuous, and the disturbance of the water-level not so violent. Some of the tubes, which are not as highly heated as the rest, act as downcomers, while in some others the flow is alternating in direction. When the external downcomer is used an improvement is observable in the general circulation; there is less alternating flow, but some of the tubes still act as downcomers. When the other half of the boiler is used, in which the tubes discharge above the water-level, there is, of course, no circulation until boiling begins, but on this account steam begins to be formed in the tubes nearest the fire almost immediately after the heat is applied. This steam projects the water in the upper part of the tubes into the steam drum, cool water flowing from the drum through the downcomer to take the place of the water thus discharged. The action during warming up, then, is of an intermittent character but, as the average temperature of the water in the whole boiler is increased, the intervals between the discharges become less and less, and when the boiler is working at a high rate of evaporation the action is quite continuous. Each half of this model consists of sixteen tubes, in four rows, each tube being $\frac{7}{16}$in. internal diameter, and the tubes in the different rows are opposite the spaces in the other rows. The internal diameter of the down-comers is $\frac{11}{16}$in., therefore the area of each downcomer is equal to $\frac{1}{5\cdot4}$ of the area of all the tubes served by it.

Model of Thornycroft boiler (Fig. 7).—This consists of twelve tubes, $\frac{7}{16}$in. internal diameter, with a downcomer $1\frac{3}{8}$in. diameter. The area of the downcomer is therefore approximately equal to the area of the tubes served by it. When heat is applied to this boiler, an intermittent discharge of plugs of water is almost immediately set up, due to formation of steam in the tubes, although the water in the upper and lower drums is practically cold. This action is obviously of great service in preventing overheating of the upper portions of the tubes which, before this action commences, do not contain water. In actual boilers of the Daring type, with internal heated downcomers, circulation of water between the drums will be started through the downcomers as soon as the fires are lighted. As before remarked, at high rates of evaporation, even with tubes below $\frac{1}{2}$in. in diameter, the water and steam do not follow each other in plugs; the upper halves of the tubes are more or less filled with coarse foam, to the complete exclusion of continuous water. Under these conditions the circulation is wonderfully active, and the water part of the foam is projected in a continuous stream right across the steam drum, as

---

[*] Read at the Thirty-seventh Session of the Institution of Naval Architects, March 26th, 1896

[†] From a paper by the author, Inst. Engineers and Shipbuilders in Scotland, January, 1895.

shown, the steam being given off freely, and the water level is only very slightly disturbed.

Model of Babcock boiler (Fig. 8).—This model consists of three tubes, each $1\frac{7}{16}$in. internal diameter, and the distance between the centres of the headers is 33in. The tubes are inclined at 15 deg. to the horizontal. The circulation in this case is due partly to the entraining action of the bubbles moving through the inclined tubes, partly to the foam filling the upper ends of these tubes, but mainly to the column of foam in the front header. When the level of the water before starting is below that of the bottom of the steam drum, a much smaller drum may be used, without priming taking place, than when the water-level is above. When the water-level before starting is below the bottom of the steam drum—see Fig. 8, line A B—as soon as the boiler has got into full action a large amount of water is carried up into the drum along with the steam, and there is a continuous and very rapid flow of water along the bottom of the drum, as shown.

Model of Niclausse boiler (Fig. 9).—In this model there are five tubes, each 1in. internal diameter and 18in. long. The internal tube is $\frac{3}{8}$in. internal diameter, and the inclination is 15 deg. The action is practically the same as in the Babcock boiler.

Effect of inclination of tube on velocity of circulation.—When each tube draws its supply of water directly from the water drum, and discharges it directly into a steam drum, the greater the inclination of the tubes to the horizontal the better the circulation. If the tubes draw their supply from, and discharge their steam into, headers, the inclination of the tubes does not greatly affect the circulation, providing it does not fall below about 15 deg., and providing the currents from the different tubes do not interfere with each other. This is because the circulation in boilers of this type is mainly due to the low density of the foam in the upper part of the front headers. When the inclination is much below 15 deg., no matter whether the supply of water to the tubes is from a back header or is by means of internal tubes, the circulation is largely local, and the amount of water in the tubes is very small. When the tubes are only slightly inclined to the horizontal, the only safe way of preventing the water being driven out of them is to use a non-return valve, or a very contracted orifice at the lower end of each tube; with a non-return valve the tubes may be quite horizontal.

Relative advantages of above and below water delivery of steam.—When the discharge takes place just at the water-level, it seems evident that the velocity of circulation must be a maximum, because the head of water effective for circulation is the same, whether the discharge takes place at or below the water-level. In the latter case, however, part of the energy due to this head is expended in giving motion to a considerable body of water in the drum, and the velocity of circulation through the tubes must necessarily be less than when the discharge takes place at the water-level. If tubes are carried much above the water-level the circulation is, of course, reduced in these tubes. When the discharge takes place above the water-level the area of the downcomer is constant under all conditions, but when the discharge is below, this area varies even when external downcomers are used, because the number of tubes acting as downcomers varies with the rate at which steam is being generated. When the discharge takes place above the water-level a much smaller drum may be used for a boiler of a given power, and priming is less likely to take place, because the water level in the drum is only very slightly disturbed, whereas when the discharge takes place below the water-level the disturbance is considerable. Should straight or curved tubes be used? From what has been said in connection with the action of the boilers when the fires are first lighted, it will be evident that when the discharge is above the water level, some parts of the boiler may be at a very much higher temperature than other parts. From this it seems to follow that, when the discharge is above the water level, provision must be made for free expansion of the tubes, either by bending them or by leaving the ends free, as in the boilers of Belleville and Niclausse. When the discharge is below the water-level, the temperature throughout will never differ much from that of the water, providing the circulation is good, and in this case straight tubes may be used without difficulty. The author has found, by calculation, that when evaporating at the rate of 20 lb. of steam per square foot of heating surface, the difference in temperature between the inside and outside of the tube is only 2·6 deg. Fah. for each $\frac{1}{16}$th of an inch in thickness of the tube in the case of steel. The temperature of the metal will, of course, be a few degrees above that of the water, but the more rapid the circulation the less the difference in temperature between the water and the tube. When working at the above rate, if the water be entirely driven from the heating surface for one second, and the thickness of the tube is $\frac{1}{8}$th of an inch, the rise in temperature in that time will be less than 10 deg. Fah. Assuming a difference of even 100 deg. Fah. between the temperature of some of the tubes and that of others, the difference in length in the case of a tube 5ft. long due to this difference in temperature would be only ·04 of an inch. If the external diameter of the tube be $1\frac{1}{8}$in. and its thickness $\frac{1}{8}$th of an inch, the force necessary to prevent any increase in length due to this increase in temperature is 3·15 tons. This corresponds to about eight tons per square inch of the metal, which is sufficiently below the limit of elasticity of mild steel to prevent injury to the boiler, even should the above unlikely difference of temperature ever exist between the different tubes of the boiler. By using bent tubes it is possible to obtain a much larger amount of heating surface for a given number of joints, and a given amount of space occupied by the boiler.

Relative advantages of heated and non-heated downcomers.—With a given rate of evaporation from a given amount of heating surface, the greatest velocity of circulation will be obtained when all the heat is supplied to the upcomers; but if additional heat be applied to the downcomers, the velocity of circulation will be increased, so long as the amount of heat supplied to the downcomers is insufficient to generate steam with sufficient rapidity to nearly exclude continuous water at some part of the downcomers. In all these models the velocity of circulation is increased by applying a moderate amount of heat to the downcomers. For this reason it is probable that the circulation in the Thornycroft boilers is more vigorous in those of the Daring type than in those of the Speedy type. In boilers where the discharge takes place below the water level, as in the Yarrow, Normand, Babcock, D'Allest, &c., even when special external downcomers are provided, some of the tubes most remote from the fire act as downcomers. In connection with downcomers it is important to note that the entrance to the downcomers ought to be removed as far as possible below the surface of the water in the drum, otherwise the reduction in pressure just inside the upper end of the downcomer may be sufficient to cause steam to be generated in it at that part. The steam thus formed would, of course, be condensed on its way down by the increased pressure. This action is indicated in Fig. 11. In connection with internal heated downcomers, insufficient attention has, I believe, been paid to the advantages of a few tubes of larger diameter being placed in the midst of tubes of smaller diameter.

Determination of weight of circulating water ÷ weight of feed water. — When considering the best method to be adopted in order to determine this ratio, the author first thought that the best arrangement would be by means of a circular thin-lipped orifice, of known dimensions, placed near the top of the downcomers, but it soon became evident that although this method might be adopted for cases where the discharge takes place above the water-level it could not be used in cases where the discharge is below the water-level, because in these cases some of the tubes act as downcomers, no matter how large the external downcomer may be. In order to get over this difficulty the author used the model illustrated in Fig. 10, above, which consists of only one upcomer and one downcomer. By means of the loose glass tube shown attached to the brass rod in the steam drum, the discharge may be made to take place above the water-level. After trying various methods for measuring the circulation it was found that the simple water column pressure gauge was the most convenient, and of sufficient accuracy for present purposes. In Fig. 10 this is shown attached to the top of the lower drum, another column being attached to the bottom of the steam drum as shown. The head available for circulation is the difference in the heights of these two columns, and the velocity of the water in the downcomers is proportional to the square root of this difference of levels. In connection with this, it is important to remember that this difference of level may be increased, either by an increase in the velocity of circulation, or by an increase in the resistance to the flow of the water from the upper to the lower drum. By means of the glass-tube extension to the upcomer, it was possible to take the readings of the columns when discharging above, and when discharging below the water-level, immediately after one another. To determine the weight of circulating water in each case, separate tests were made for each size of downcomer with the upcomer disconnected, and the outlet from the bottom drum contracted to give a suitable difference of level between the columns. Water at about 200 deg. Fah. was then syphoned into the upper drum, and the weight of water flowing down the downcomer per minute, and the difference of level of the column being obtained, it was possible to determine, with considerable accuracy, the weight of circulating water under the actual conditions of working as given in the above table.

The following results were obtained with this apparatus when working at atmospheric pressure and evaporating 13 lb. of water per hour; the evaporation per hour per square foot of heating surface actually subjected to flame being 10·8 lb.

Area of Down-comer.	Depression of Water Column.		$\frac{\text{Weight of Circulating Water}}{\text{Weight of Feed Water}}$		Remarks.
	Discharge above.	Discharge below.	Discharge above.	Discharge below.	
sq. in.	in.	in.	lbs.	lbs.	* The difference between these two readings was so small that it could not be read.
·087	21	18	40	37	
·359	$8\frac{1}{4}$	$7\frac{1}{4}$	147	138	
·994	$8\frac{1}{4}$	$8\frac{1}{4}$	242*	242*	

When I commenced to write this paper my intention was merely to describe the action in the various models shown, but as practically the whole of the problems connected with the design of water-tube boilers depend on the nature and amount of the circulation under various conditions, I was gradually led into a discussion of some of the most important problems which are affected by the circulation.

AMERICAN NOTES.

(*From our own Correspondent.*)

New York, March 26th.

The trade situation throughout the United States is not altogether satisfactory. Manufacturers are not working to full capacity. The banks are not accommodating customers freely. Throughout the West there is a scarcity of money that serves to intensify hostility to the present administration.

Conditions are improving slowly in most lines, but in several, raw material, such as cotton, wool, ore, and coal are too high. There is a reviving demand for reciprocity arrangements, and steps will be taken next month under the new republican silver president the people will elect, to return to the discarded reciprocity policy.

The Brazilian and Argentine Governments have extended an invitation to the Chambers of Commerce of our leading American cities to visit those countries this summer to arrange for the establishment of banks and steamship lines, and save us and them the circuitous methods of business, *viâ* Liverpool and London. The iron trade don't know whether to cry or not. Business is not up to expectations.

Pig iron accumulates. Billet mills have too many furnaces idle. Rolling mills are reducing output. Summer orders are not coming in, though promised. There is a general holding-off policy among large buyers. Railroad companies are still economising. Locomotive builders are hopeful of catching good home and foreign orders next month. Recent estimates of cost of pig iron show cost at Southern furnace to be 7·50 dols., at Eastern Pennsylvania furnace 9·60 dols. High freight rates work against the long hauls of southern pig into northern markets. The best posted in the American iron trade have the least to say these days. Political questions are calculated to restrain activity. The consumers demand cheaper Lake ore and cheaper coke, but the dozen men who control these products are hard of hearing.

Trade and Business Announcement.—Mr. W. Schroller, of Old Elvet, Durham, announces that he has changed his address to 38, Claypath, Durham.

A Local Government Board Inquiry was held, on the 19th inst., by Mr. Rienzi Walton, C.E., into an application of the Todmorden Urban District Council to borrow £40,000 for sewerage and sewage purification purposes. Evidence in support of the application was given by Mr. Shaw, surveyor, Dr. Thorp, the medical officer, and Mr. A. Crossley, chairman of the Sewerage Committee. Mr. Sutcliffe, the clerk to the Council, stated that the sewage would be treated by the International system, precipitation by ferozone, and filtration through polarite.

RAILWAY MATTERS.

The text of the edict of the Emperor of China relating to railway construction shows that the Emperor now, without doubt, recognises the importance of railways in peace as well as in war.

Mr. William Pollitt, of Fornlea, Bowdon, the general manager of the Manchester, Sheffield, and Lincolnshire Railway Company, has been put upon the Commission of Peace for the County of Chester.

In the German Empire 1087 miles of new railways were opened during the year 1895, as compared with 500 miles in 1894. About 435 miles opened last year were built under the provisions of a Prussian law of 1893, providing for light railways and private lines making junctions with established lines. The longest single line opened had a length of less than 45 miles.

A German resident at Mombassa writes, says the Berlin correspondent of the *Standard*, that the staff of sixty Europeans and about eleven hundred labourers, who have been sent from British India to assist in the construction of the Uganda Railway, have been quartered near Mombassa since the middle of last month. The scarcity of water for the first hundred miles or so will be met by the use of sea water condensing apparatus.

A good deal of public interest attaches to the Ahmedabad-Parantij railway line from the fact of its being the first railway constructed by private enterprise in India with rupee capital. Lord Sandhurst, Governor of Bombay, recently performed the ceremony of cutting the first sod of the line. The necessary funds have or had to be desposited with the Bombay-Baroda and Central India Railway Company, which is to construct and work this feeder line to its system.

Under instructions from the Secretary of State, the Government of India has issued orders to the agents and managers of the metre-gauge State Railways in India, through their respective Governments, to afford every facility to Mr. T. H. Trevithick, Superintendent of Locomotives and Rolling Stock of the Egyptian Railway Administration, who is to make a tour in India with a view to acquaint himself with the metre gauge rolling stock used in this country for the purpose of adopting the same for use on the Egyptian line now under construction from Kineb to Assouan.

On Saturday last an inaugural trip upon the North Wales and Liverpool Railway was made, Mr. and Mrs. Gladstone being of the party. The line is only fifteen miles in length, but it is one that cuts through a portion of Cheshire hitherto untraversed by a railway, joins the existing Mersey Railway under the river, and gives to Liverpool a direct access to North Wales. Mr. Pollit, chairman of the new railway, and general manager of the Manchester, Sheffield, and Lincolnshire Railway, presided, and gave the health of Mr. and Mrs. Gladstone, who were present, which was cordially received.

The Directors of the South-Eastern Railway Company received on Monday, at the Charing Cross Hotel, a Sub-Committee representing the agriculturists of the whole district served by the line, in order to consider the proposed reduction of rates on agricultural produce. The discussion was of the most friendly character, and a number of important reductions were agreed to, subject to confirmation by the London, Chatham, and Dover Company. An arrangement to lower the rates for the carriage of milk by 15 per cent., and for small parcels up to 56 lb. by 30 per cent., will take effect on and after Saturday next.

The experimental car of the New York and Brooklyn Bridge Railroad, equipped with four 50-horse power electric motors, has been subjected to tests in shunting trains at the Brooklyn terminus, and is reported to have saved about half the time required to shunt trains by the steam locomotives. At a meeting of the Bridge Trustees, February 10th, Chief Engineer Martin submitted a report on the successful trial of electricity on the railway, and recommended that a contract be made with the General Electric Company for equipping sixteen cars with the necessary electric apparatus. The report was adopted.

An influential syndicate in London has put forward a proposal to connect the East Indian with the East Coast Railway by a line between Raniganj on the former and and Midnapur on the latter. The importance of this proposed connecting line can hardly be over-estimated, for it will not only afford the much-needed direct route to Juggernath—Puri—for the north-western pilgrim traffic, but, better still, says the *Indian Engineer*, from an industrial point of view, bring the coalfields of Jherria and Raniganj into immediate touch with the Southern Presidency. In addition to these desiderata, a large and new area for produce will be effectually tapped in the interests of mercantile Calcutta.

Official returns regarding the rail and river-borne trade of Bengal during the quarter ending the 30th September, 1895, show a decrease of 9,59,868 maunds, or 11·94 per cent. in the total external trade of the Lower Provinces, in comparison with the corresponding period of the year before. The falling off occurred entirely under imports, which decreased by 17,24,518 maunds, or 41·49 per cent. This was due to an absence of demand for export to Europe. The decrease was especially conspicuous in the consignments for Calcutta and Behar from the North-Western Provinces and Oudah and Punjab. As regards exports, there was an increase of 7,64,650 maunds, or 19·17 per cent. The largest increase was in the import of rape and mustard seed, which amounted to no less than 1,71,654 maunds, and was due to a good demand in Calcutta for local consumption.

It is reported that successful arrangements for preventing damage to merchandise through excessive cold have been experimented with on a German railway. The winter 1894-5, which was particularly severe throughout Central Europe, caused great losses of perishable freight in transit during the winter months. It was, therefore, proposed to heat freight cars carrying such goods. A stove in the centre part of the car, which is fed from without, supplies the necessary warmth, and a thermometer, which is visible from the outside, reveals to the inspector, whose duty it is to ascertain the temperature of each car at every station, whether he has to open the ventilators on top to reduce the heat, or whether new fuel ought to be introduced to keep up the fire and increase the temperature. A slight additional freight is charged, and as the shippers prefer this increase to the uncertainty of the weather, the *Railroad Gazette* says, the entire system is said to have been pronounced a success on all sides.

A company is likely to be formed for the purpose of acquiring the tramways in Middlesbrough, Thornaby, and Stockton, and working the same by the overhead electric system. The tramways at Middlesbrough are owned by the Imperial Tramway Company, and are worked by horses, while those at Stockton and Thornaby are owned by the Stockton and Darlington Tramways Company, and are worked by steam power. Mr. Emile Garcke, the engineer of the British Electric Traction—Pioneer—Company, has just inspected the Stockton Company's lines, and also those of the Imperial Company's at Middlesbrough, and as a result a scheme has been formulated to acquire the entire properties of both companies if the local authorities would assent to the construction of the requisite overhead electric plant. The Stockton authorities have refused permission. It is, therefore, now intended to obtain the assent of the Town Councils of Middlesbrough and Thornaby, and if it is granted, the Stockton and Darlington Tramway Company and the Imperial Tramway Company will be amalgamated, so far as Middlesbrough and Thornaby are concerned. New lines will be laid down of a uniform gauge, and a connecting line constructed between Thornaby and Newport.

NOTES AND MEMORANDA.

Aluminium is now being used instead of magnesium for "flash-light" photography. The light is said to be equally actinic, while *Aluminium* say the metal keeps better and burns away more completely.

It is stated that after an aluminium cooking utensil has been in use for some time, a brown enamel or coating is formed on the inside, which is perfectly harmless, and Messrs. Bowen, of the Phœnix Foundry, Clerkenwell, say this acts as a protection to the surface of the metal.

An American contemporary makes the statement that the greatest corporation on earth is the London and North-Western Railway Company. It has a capital of 595,000,000 dols. and a revenue of 6500 dols. an hour; has 2300 engines, and employs 60,000 men. Everything is made by the company—bridges, engines, rails, carriages, wagons, and an innumerable lot of other things; even the coal scuttles and wooden limbs of the injured of its staff.

The Philadelphia Natural Gas Company, of Pittsburg, have a larger supply of gas for their private customers than at any time within the past three years. The prices charged are:—For the first 500,000 cubic feet or part thereof consumed per month, 15 cents per 1000; for the second 500,000 cubic feet or part thereof consumed per month, 10 cents per 1000; for all over 1,000,000 cubic feet consumed per month, 8 cents per 1000, subject to the conditions and provisions of the regular form of contract.

The decomposition by shock of endothermic compounds, discovered by M. Berthelot, and the explosion of carbon bisulphide vapour described by Dr. Thorpe, led Messrs. H. B. Dixon and J. A. Harker to determine whether a true explosion-wave was transmitted through these compounds. The results of their experiments are given in the Chemical Society's *Journal*. It was found, however, that when a charge of fulminate was fired in a steel bomb attached to a long tube filled with cyanogen or acetylene, the detonation was not transmitted through the gas in the tube except for a short distance. With carbon bisulphide the flame extended for some distance, but gradually died out. M. Maquenne has recently obtained similar results. It would appear from the experiments that a true explosion-wave is propagated through chlorine peroxide.

In view of the enormously increased consumption of platinum in electrical work it is agreeable, says the *Engineering and Mining Journal*, to note the well accredited statement that large deposits of this valuable mineral have been discovered at Fitfield, New South Wales. It has been known for several years that platiniferous lead existed in this locality, and the deposits have been worked, though only on a small scale. It is now found, however, that the platiniferous lead is over a mile long, varying in width from 60ft. to 150ft., and covered with from 60ft. to 70ft. of loam. The precious metals are practically confined to the bed-rock and the drift for 3in. above the bottom. Nuggets which weighed from a few grains up to 5 dwt. have been occasionally found. The crude metal contains about 75 per cent. of platinum, and realises at the present time upon the field 24s. per ounce.

In a recent paper read before the Chemical Society "On the Mode of Formation of Carbon Dioxide in the Burning of Carbon Compounds," Mr. H. B. Dixon, F.R.S., says:—"Assuming that in the combustion of carbon compounds the carbon burns first to carbonic oxide, the author discusses the views that have been advanced concerning the function of steam in promoting the union of carbonic oxide and oxygen. Professor Armstrong considers that the moisture acts as an electrolyte, and that chemical change only takes place when carbonic oxide, steam, and oxygen are in contact. The chief difficulty in this theory is to account for the great velocity with which the explosion wave is propagated through a damp mixture of carbonic oxide and oxygen. In gaseous mixtures the rate of explosion approximates to the rate of the forward movement of the reacting molecules, *i.e.*, the wave is transmitted like sound from molecule to molecule. According to the electrolytic theory, the chemical change could only occur on the simultaneous collision of at least three molecules; yet the explosion wave is propagated in carbonic oxide, steam, and oxygen at a rate of 1738 metres per second. In the explosion of cyanogen, carbon dioxide is formed without the intervention of steam. This theory, which has the advantage of including a number of cognate phenomena, seems better suited to explain reactions at ordinary temperatures than those occurring in the explosion wave."

In a recent paper before the Geological Society on "Observations on the Geology of the Nile Valley, and on the Evidence of the Greater Volume of that River at a former Period," Professor E. Hull, F.R.S., drew attention to the two great periods of erosion of the Nile Valley, the first during the Miocene period, after the elevation of the Libyan region at the close of Eocene times, and the second during a "pluvial" period extending from late Pliocene times into and including the Pleistocene. He notes the course of the river through escarpments of the granitic and schistose rocks of Assuad, the Nubian sandstone, the cretaceous limestone, and the Eocene limestone, and observes that in places the line of erosion of the primæval Nile was directed by dislocations of the strata. In a second part of the paper he dwelt on the terraces of the Nile Valley, and the characters of a second terrace, at a height varying from 50ft. to 100ft. above the lower one, which is flooded at the present day. The second terrace is devoid of vegetation, and its deposits have frequently furnished river-shells. The second terrace is traceable at intervals for a distance of between 600 and 700 miles above Cairo. Two old river channels are also described, one at Koru Ombo, and the other at Assuan itself. The author discussed the mode of origin of the second terrace and the old river valleys, and believes them to be due to the former greater volume of the river, and not to subsequent erosion of the valley. He gave evidence of the existence of meteorological conditions sufficient to give rise to a "pluvial" period, and points out that other authors have also considered that the volume of the Nile had been greater in former times.

Some very interesting tests which have been applied to standard Clark cells have recently been described in the *Electrician* by Mr. Fisher. The cell used is Muirhead's, in which the positive pole consists of a spiral of platinum wire amalgamated and filled with mercury. It is very generally believed that if by any chance a Clark cell becomes short-circuited, then the cell is either totally ruined or only recovers after a very long time. Mr. Fisher has shown that the Clark cell will stand very much rougher usage than one would think, and still recover even in a very short time. In one set of experiments a Muirhead pattern cell had for one minute a potential applied to the terminals of $\frac{1}{100}$ volt in excess of the electromotive force of the cell. As a result, the electromotive force rose about three parts in 14,000, but regained its normal value after ten minutes. After short-circuiting for one minute through 500 ohms the electromotive force fell from 1·4323 volts to 1·431, but recovered its normal value after thirty minutes. Short-circuiting the cell through 2in. of No. 18 copper wire for thirty seconds caused a drop from 1·4319 volts to below 1·431, but after thirty minutes it had almost recovered. A cell having been short-circuited through a few inches of copper wire—No. 20—for twenty hours, its electromotive force fell to 0·17 volt. The recovery was at first very slow, and continued so till it reached 0·5 volt, the average rate of recovery being 0·03 volt per hour. After this the recovery was much more rapid, and in twenty-four hours the cell had almost completely recovered. The effect of applying a constant potential of 1·4 volts to a cell which had been "dead" short-circuited for twenty hours, was to very much hasten the recovery, so that after two and a-half hours it had regained its former value.

MISCELLANEA.

Richmond residents in the neighbourhood of Petersham-road and the main streets of the town were during last week somewhat troubled by a series of concussions underground, which they attributed to various alarming causes. They were, however, only the effect of the heavy gelignite shots fired in the Richmond well adits, in the hope of increasing the water supply.

In accordance with a recent amendment to Section 63 of the Baltimore City Code, the City Commissioners hereafter are to be civil engineers. The Code says:—"There shall be appointed biennially in the month of March, by a joint convention of the City Council, a City Commissioner, who shall attend daily at his office, and there shall be also appointed three Assistant Commissioners, who shall be under the direction of the said City Commissioner; said City Commissioner and Assistant City Commissioners to be practical civil engineers of not less than five years' actual experience, and the entire time of both commissioner and assistants shall be devoted personally to the interests of the Corporation; and should it be ascertained that any of the aforesaid officers is engaged in or connected with any business or pursuit other than that appertaining to his official duties, it shall be deemed good and sufficient cause for his removal."

After experiments extending over a period of two years, the Admiralty have now decided to generally adopt the "Temperley Transporter" for use in battleships and first-class cruisers. It is probable that the apparatus would have been adopted before had it not been for its awkward length and the difficulty of stowing it clear of the working parts of the ship. The trials, however, says the *Naval and Military Record*, have resulted in most favourable reports, and the commanding officers of the vessels in which the transporter has been tried are unanimously of opinion that the time and labour saved when coaling ship far outweigh the inconvenience occasioned by stowing the gear away. Apart from this, it has been found that the transporter will enable a torpedo boat or destroyer to fill up with coal from her parent ship when both vessels are steaming at a fair rate of speed, pro viding, of course, the sea is moderately calm.

The fate of Bruxelles, port-de-mer, hangs once more in the balance. It may be remembered that the contract for the conversion of the capital of Belgium into a seaport was signed on October 21st last, the cost of the undertaking, estimated at £1,400,000, being divided between the State, the city of Brussels, the suburbs, and the provinces. Latterly, however, a modification of the original plan has been proposed by the Minister of Finance, following which the waterway would be carried through the plain of Monplaisir, instead of that of Tour and Taxis. The *Times* Brussels correspondent says this scheme, while connecting the docks with the line of the Metropolitan Railway now under consideration, would have the effect of removing them further from the capital. The town of Brussels resents the Minister's interference, and at a meeting of the Communal Council M. Buls, the burgomaster, has moved that Brussels should withdraw the promised subsidy, and refuse all participation in the enterprise in its altered form. The vote upon the motion was adjourned.

The building up of industrial towns in the natural gas regions of Ohio and Indiana during the past few years has been marvellous. In the glass trade particularly these new conditions have been felt, and the centres of business have shifted westward. It has since been demonstrated that the supply is limited. Now the manufacturing concerns, built on practically free fuel, are wondering what is to be done when the gas becomes exhausted. A recent dispatch to a leading Chicago journal states that the Chamber of Commerce of Brazil, Ind., is in receipt of many letters from manufacturers in the actual gas belt, stating that they realise that the life of the gas is not more than four or five years, and that they are taking time by the forelock in arranging for a suitable location in the coal fields when the blow comes. Some, the *American Manufacturer* says, are securing all new gas territory they can. If the next few years do not develope some great changes in the production and application of fuel, there will be some very cheap factories in the western gas belt.

The Renown, battleship, was taken on the 27th ult. into the Channel by Captain H. Rose for the first of her series of official speed trials. The trial was of eight hours' duration, with natural draught, and throughout the engines and boilers worked satisfactorily. The *Times* says the mean results were:—Steam, 143 lb.; vacuum, starboard 26·9in., port 26·9in.; revolutions, starboard 97·5, port 98·2; indicated horse-power, starboard 5233, port 5475—total, 10,708; speed, 17·9 knots. Messrs. Maudslay, Sons, and Field, the makers of the machinery, were responsible for an indicated horse-power of 10,000 only on the natural draught trial, but more than once on Friday's steaming the engines easily attained 11,000 indicated horse-power, while the mean was 708 in excess of the stipulated power. The mean speed was exactly one knot more than her designers anticipated that the vessel could attain on her natural-draught trial, and two-tenths of a knot more than it was estimated she would steam under forced draught with 12,000 indicated horse-power. The Renown returned to the Hamoaze in the afternoon to be prepared for a four hours' forced-draught trial on the 6th inst. Before she passes into the Reserve she is to carry out a thirty hours' full-power trial in the Channel.

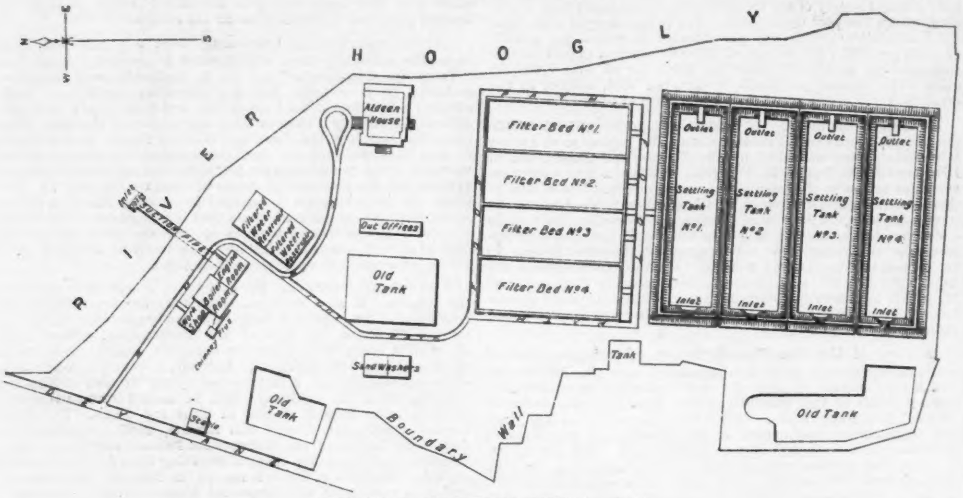
The following resolution has been passed by the Grand Jury of County Waterford:—"That having learned that there is a probability of torpedo boat stations being established at several ports upon the Irish coast, we wish to point out the strong claims that Waterford possesses for selection. The harbour is spacious, safe, and easily entered at all times; it is the only harbour between Queenstown and Kingstown, being 60 miles from the former, and 110 miles from the latter, while it is 80 miles from Pembroke Dock. From its geographical position it commands the approaches to St. George's Channel and the Bristol Channel. It has two piers, one at Duncannon and one at Dunmore, and at both places the Government possesses ample accommodation for coal stores. Dunmore is practically upon the sea, and in addition to affording a safe berthage, has a good anchorage off its entrance, making it suitable for occupation by torpedo boats; so having regard to these considerations, and to the fact that since Duncannon has been abandoned as a fortress, leaving no defence of any kind for the harbour, we are strongly of opinion that, both on imperial grounds and the grounds of its local utility, the claims of Waterford to be made a torpedo boat station are greater than any port in Ireland."

The screw steamer Algoa, which has recently left the hands of her builders—Messrs. Doxford and Sons, Sunderland—in addition to being the largest cargo boat ever built on the Wear and the third largest deadweight carrier afloat—being in that respect beaten by the Georgic and her sister ship the Civic of the White Star Line, built by Messrs. Harland and Wolff—possesses several other points for which she is noteworthy. She is plated on the Bell-Rocliffe system, whereby packing is dispensed with, and on this account is some 68 tons lighter than if plated on the old system, and has a very large number of steam derricks on board—eighteen—and is further equipped with a new design of steering gear, the invention of Messrs. Fawcet, Preston and Co. This gear is worked on the hydraulic principle, having attached to it a duplex steam pump. For the hydraulic cylinders oil is used instead of water to obviate the chance of the fluid being affected by frost. The advantages of gear on the hydraulic principle over the ordinary steam steering gear are numerous. It is noiseless and safer, inasmuch that it has not connected with it chain and toothed gearing, and there is less likelihood of a breakdown if a sea strikes the rudder. The hydraulic cylinder applying the power also acts as an elastic brake, and allows the rudder to give way before the sea. By an automatic readjustment arrangement the rudder is afterwards replaced in position. The Algoa is owned by Messrs. Crow, Rudolph, and Co., Liverpool.

HOWRAH WATER SUPPLY.

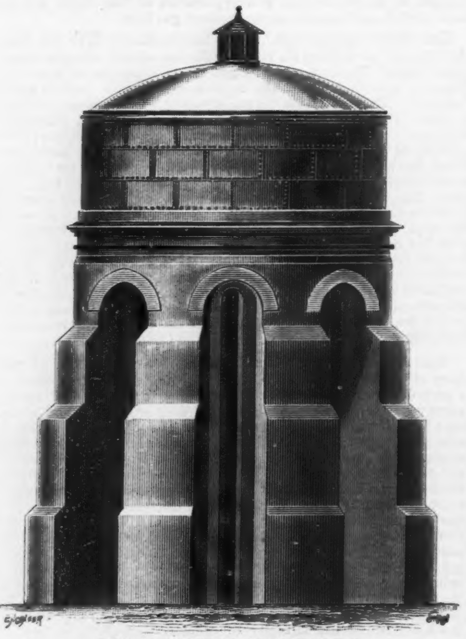
The waterworks are designed to provide a domestic water supply of 1,250,000 gallons a day, or 10 gallons per head, for a population of 125,000 persons in the Howrah Municipality. The water is pumped against a total head of 42ft. from the river Hooghly at Serampore through a 22in. steel hydraulic riveted suction pipe, carried out into the river on a wrought iron screw pile jetty, 130ft. in length. The mouth of the suction pipe, which is protected by a rose, is 12ft. above bed of river, and will be always covered with water at the lowest known river level.

The river water is delivered into four settling tanks, a distance of about 1500ft. from the engine house, by duplex compound condensing steam pumping engines, of which there are two sets, each capable of pumping 1,300,000 gallons in ten hours, or a little more than a day's maximum demand. The settling tanks are 250ft. long by 100ft. wide at bed level, each capable of holding a day's supply. They are constructed with earth banks, the slopes being 2 to 1 outside and 1½ to 1 inside. The width at crest is 8ft. The water is delivered into masonry inlet chambers forming a trough and tumbling weir about 40ft. in length. After the water has been allowed to settle for about three days, it passes by gravitation through iron pipes to the filters, the take-off being always surface water. This is accomplished by means of floating pipes supported by small jetties.



HOWRAH WATERWORKS—GENERAL PLAN

The filters are four in number, 181ft. long by 81ft. wide, each having an area of 14,661 square feet, and the process is mechanical through filtering media consisting of fine sand, coarse Mugra sand, pebbles, and close-jointed bricks, the whole being supported on brick channels laid on a masonry floor. The water, after filtration, passes along a masonry channel, formed in the centre of the filter, to the filtered well, where the results of filtration can be observed. From this well the water is delivered, also by gravitation, through iron pipes to the underground filtered water reservoir, a distance of about 500ft. from the filters. The reservoir is divided into two compartments each holding 183,000 gallons of water, and each formed by a series of five masonry-arched passages, supported by masonry walls, with an opening at one end for the passage of the water. These are so arranged as to ensure circulation of the water during filling and emptying, thus advoiding any chance of stagnant water at any point in the reservoir.



TOWER—HOWRAH WATERWORKS

From the filtered water reservoir the water is pumped against a total head of 215ft. by duplex compound condensing pumping engines, of which there are two sets, to the three raised reservoirs in Howrah, and, practically speaking, the water does not see the light after leaving the filters, until it is taken from the standposts in Howrah. These three reservoirs, which supply three sections of Howrah with water, are circular in shape, and constructed of masonry piers arched across to form the flooring for the iron tank. No. 1 reservoir is 60ft. in diameter and holds 176,714 gallons of water. No. 2 is 65ft. in diameter and holds 207,394 gallons of water. No. 3 is 36ft. in diameter, and holds 63,619 gallons of water. The height of the three reservoirs to full supply level averages 51ft. above ground level. From the three raised reservoirs the water is distributed through 37 miles of iron pipes, varying in size from 16in. bore to 2in. bore, to the different roads and lanes of the town.

Along the pipe lines are placed 120 sluice valves, by means of which any line of pipes can be shut off from supply. For the use of the public there are placed 240 taps on standposts, the design being such that water can only be obtained so long as the tap is held open by the hand, thus preventing waste. In addition to the 37 miles of distribution pipes, there are 15 miles of main piping, principally 15in. bore, between Serampore and Howrah, and to provide against the discharge of the water backwards, through the main, eight reflux valves are placed with sluice valves and scours. In the event of a fracture occurring between the head works and the reservoirs, the water can be at once shut off, and only a small portion of the pipes requires to be emptied. The mains are also provided with air valves. The supply pipes to the raised reservoirs in Howrah are so arranged that, in case of anything happening to the reservoir, the water can be supplied through a by-pass direct to the town distribution.

The engines are of a very high class, both in design and finish, and embody all latest improvements. A remarkable feature in their design is that for the high and low-pressure cylinder only one casting is used, this being double the length of the stroke, and the high-pressure cylinder is formed by means of a trunk connecting the two pistons. The valve gear has Evans' improved valve motion, and the cut-off valves, which are most perfect in their action, are of the circular type, driven direct from the crossheads, so that the point of cut-off, and thereby the number of expansions, can be regulated while the engines are in motion. The unfiltered engines have each two high-pressure cylinders of 8in. and two low-pressure of 14in. diameter by 18in. stroke, and the filtered engines have each two high-pressure cylinders of 11in. and two low-pressure of 20in. diameter by 12in. stroke. Steam is supplied by three Lancashire boilers, each 28ft. long by 7ft. diameter, any two of which are capable of doing the work required. An economiser is fixed in the flue, between the boilers and the chimney; the waste gases passing around the pipes are thus utilised in heating the feed-water, which is pumped through them by donkey engines—in duplicate.

The contract was commenced on November 1st, 1894, and completed on January 15th, 1896, or a period of fourteen and a-half months, and the cost has been:—

	Rs.
Pipes, valves, standposts, reservoirs, tanks, buildings, and jetty, &c.	11,34,500
Engines and boilers..	1,30,000
Land, preliminary expenses, establishment	1,30,000
Or a total of	13,94,500
Against the estimated cost of	14,86,980
Showing a saving of..	92,480

The works, which in Bengal are next in extent to those of Calcutta, have been carried out under the supervision of Mr. W. Parry, M. Inst. C.E., as resident engineer for the municipality, and Messrs. Burn and Co., of Calcutta and Howrah, have been the contractors for the whole, including the engines, which were supplied by Messrs. Joseph Evans and Sons, of Wolverhampton. The works were opened on February 8th last by Sir Alexander Mackenzie, K.C.S.I., the Lieutenant-Governor of Bengal.

THE INSTITUTION OF CIVIL ENGINEERS.

THE THERMAL EFFICIENCY OF STEAM ENGINES.

At the ordinary meeting on Tuesday, March 24th, Sir Benjamin Baker, K.C.M.G., the president, in the chair, the paper read was entitled "The Thermal Efficiency of Steam Engines," by Captain H. Riall Sankey, R.E. (ret.), M. Inst. C.E. The question of the standard with which the results of steam engine trials should be compared had occupied considerable attention in several papers on steam engine economy which had during the past fourteen years been read and discussed at the Institution. The matter was nevertheless in an undecided condition, and the author expressed the hope that discussion on this paper might prepare the way for the adoption of some definite standard. He urged that in order to obtain full information of the thermal performance of an engine, two efficiencies had to be stated, namely, the absolute thermal efficiency, and the "standard" thermal efficiency, the latter denoting the comparison of the actual engine with an ideal steam engine working within the same temperature limits. In other words, the "standard" thermal efficiency was the absolute thermal efficiency of the actual engine divided by the absolute thermal efficiency of the ideal steam engine chosen as the standard. It was the choice of this standard which had caused so much discussion. Many views were held as to what should constitute the ideal engine required for this standard of comparison; but the author considered that the true object of such a standard was to provide ready indication as to how far the particular engine under consideration fell short of what was physically possible within the limits of temperature by which the engine was bound, having regard also to the varying temperature at which the heat was supplied to the feed-water. It was shown that this requirement was met by the Clausius "perfect" steam engine, slightly modified, however, as regards the point to which the expansion was carried, for practical reasons which were universal and permanent.

To assist in a decision as to the standard to be adopted, other ideal engines which had been proposed or used as standards were considered; for instance, the Carnot cycle, the engine whose expansion line was the saturated steam line, and the engine the expansion line of which followed the law $p\,v = \text{constant}$; and in each case it was pointed out in what respects the requirements of the standard were not fulfilled. This comparison was also made by means of the $\theta\,\phi$ chart.

After considering certain points in connection with the various lines of the indicator diagram of the standard in greater detail, the author proposed the following as the standard of comparison:—(1) Admission line at the temperature of the steam at the stop valve of the engine; (2) expansion line adiabatic, and carried to within 0·15 atmosphere of the back pressure; (3) back pressure, that in the exhaust immediately outside the engine; (4) compression nil, and clearance nil.

The object of limiting the expansion, as suggested, by carrying it down to within 0·15 atmosphere of the actual back-pressure was to obtain a compromise between the two following conditions:—If the expansion were carried to the back-pressure, the standard would lead to the use of engines too large for their work; if, however, the expansion in the standard were only carried to a pressure equal to the back-pressure plus the mean pressure—referred to the low pressure—corresponding with the friction of the actual engine, a premium was, so to speak, awarded to a stiff engine, and the standard would be made to vary with the stiffness of the actual engine. To avoid the lengthy calculation of the absolute thermal efficiency of the proposed standard, curves had been prepared enabling the required result to be obtained by inspection, and numerical examples were given to show the method of application.

The author pointed out that in many cases a comparison of the actual engine with what he proposed to call the "type" standard was useful. The type standard was an ideal engine which took into account the clearance, compression, back-pressure, &c., necessary with the particular type of engine under consideration. For instance, the ideal engine with an expansion line following the saturation line was the type standard for a jacketed engine. The difference in the amount of heat utilised by the standard and the type standard showed the unavoidable loss normal to the particular type of engine, whereas the difference in the heat utilised by the type standard and the actual engine gave the more or less avoidable loss.

The proposed standard was applied to the case in which superheated instead of saturated steam was used, and the $\theta\,\phi$ diagram of this standard was given, and two numerical examples were worked out. It was pointed out that the actual commercial criterion of a steam engine's economical performances, namely, the number of pounds of water per indicated horse-power, led to errors of about 1 per cent. as a maximum when using saturated steam; but that the error might be as much as 13 per cent. when superheated steam was used. This difficulty would be met by stating the amount of heat required per indicated horse-power, as proposed by Mr. Mair-Rumley in 1882.

The paper was accompanied by appendixes demonstrating the use of the $\theta\,\phi$ chart for finding the absolute thermal efficiency of the proposed standard engine, and an investigation of the efficiency of the fluid in heat engines in general.

LETTERS TO THE EDITOR.

(*Continued from page 345.*)

THE FIRST STEAM HAMMER.

Sir,—In your issue of the 20th inst., while referring to the works of the late Mr. Crawshay, you state:—"The first Nasmyth hammer ever erected in England was put up at these works." Permit us to say that the first order given Nasmyth for a steam hammer was for our works—see Nasmyth's "Autobiography" (Smiles), Chap. XIII., where he states:—"The first order came from Rushton and Eckersley, of Bolton, who, by the way, had seen the first copy of my original design a few years before. The steam hammer I made for them was more powerful than my own. The hammer block was of five tons weight, and had a clear fall of five feet. It gave every satisfaction, and the fame of its performances went abroad among the ironworkers. The Lowmoor Ironworks Company followed suit with an order for one of the same size and power, and another came from Hawkes and Co., of Newcastle-upon-Tyne;" and in Chap. XV. he mentions the working of this hammer in the presence of the Admiralty representatives.

It may be of interest to your readers to know that this hammer is still in use. Charles Harrison.

Bolton, March 25th.

NAVAL ARCHITECTURE—NO. IV., STABILITY.

Sir,—In my letter to you on the above subject, which you kindly inserted in the last number of your valuable paper, it should read, "b_1 b_2 b_3 will be the three vertical centre lines of three different centres of buoyancy, because in each case we have a simple balance with the weight of the ship G at one end and the ballast W at the other." F. W. C.

March 28th.

Sir,—Your correspondent "F. W. C.," whose communication appears in the last issue of The Engineer, has fallen into a not uncommon error in supposing that the vertical height of the shifting weight used in inclining experiments for determining the centre of gravity of a ship has any more influence upon the result than is due to the centre of gravity of the ship, inclusive of the shifting weight, being raised or lowered, according as the shifting weight is put on board at a level above or below the centre of gravity of the ship itself. If the weight to be shifted is put on the uppermost deck it will, of course, slightly raise the centre of gravity of the whole mass; and if it is put on a deck below the centre of gravity of the ship, it will lower the centre of gravity of the whole mass. But as the shifting weight bears but a very small proportion to the total weight of the vessel, and as the available vertical range in the vessel is not many feet, the vertical change in the centre of gravity is scarcely appreciable. Such as it is, an allowance is always made for it at the completion of the experiment.

But your correspondent does not refer to this small matter at all. He seems to think that the higher the shifting weight is placed in the vessel, the greater will be its effect in inclining her from the upright; and by his diagram it is clear that, in his opinion, the highest position of the weight possesses double the heeling moment of the lowest position. Herein lies the fallacy of his reasoning. The effects of the weights in the three positions are practically the same. What little differences there are consist in the fact that, when the shifting weight is put in at the highest level, the centre of gravity of the vessel is very slightly raised, and she therefore inclines a little more readily than if the weight had been put on board at the lowest level. But with the small ratio which the shifting weight bears to the displacement of the vessel, the differences are immaterial. The Writer of the Articles.

March 30th.

HORSELESS CARRIAGES.

Sir,—In your last week's issue the full text of the proposed alteration of the law contains in the first clause the words, "shall not apply to any vehicle propelled by mechanical power if it is under two tons in weight unladen, and is not used for the purpose of drawing any other vehicle, and is so constructed that no smoke or visible vapour is emitted therefrom."

These words seem to shut out from the benefit of the Act a light carriage—carrying a motor—which could be attached to all existing carriages without alteration. Probably this will deter many people from having such a tractor, which could easily be attached to either summer or winter carriages suitable for invalids.

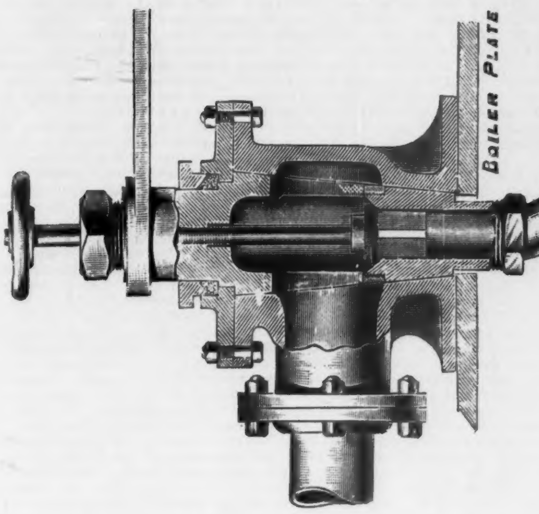
Messrs. Lister and Co., of Keighley, have been for some time engaged in perfecting a tractor which can be fitted to all vehicles without alteration, and probably other firms have it also under consideration. One advantage of the tractor is that, being a separate carriage, no vibration would be felt in any carriage to which it is attached.

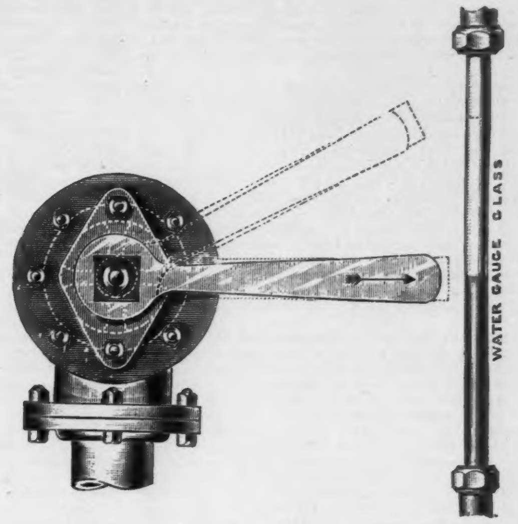
To me it seems that this should be brought to the notice of the Parliamentary Committee now inquiring into the subject.

March 30th. John Todd.

MARKS AND MORDEY'S SURFACE SCUM COCK AND VALVE

MESSRS. HUNT AND MITTON, BIRMINGHAM, ENGINEERS





MARKS AND MORDEY'S SURFACE SCUM COCK AND VALVE.

The accompanying sketches illustrate a novel invention, the object of which is to take the scum off the surface only of the water in a boiler without drawing off and wasting any body of water. The invention also fulfils the double purpose of not disturbing the scum on the top of the water by sudden withdrawal of water. By this arrangement it is possible to take the scum off the water at any height without disturbance of water or distributing the scum. The arrangement is as follows:—

The combination consists of a plug cock and a valve inside the plug, to which plug the movable pipe is connected on the tail end, and is moved into position by setting the handle to the level of the water. The handle of the plug cock is parallel to the line of the revolving arm pipe in the boiler, and when at work is set to the water level by the indication in the gauge glass, and when not at work is put into the steam space, which prevents any leakage of water through the valve. When the plug is set to the surface level of the water, the valve is opened, which releases the scum from the surface only, and does not disturb the body of the water. The scum is directed through valve to the waste pipe.

The advantages claimed are—(1) Economy of water in any position of scumming; (2) perfect scumming of the surface of the water at any level; and (3) security from leakage when not at work. The mounting is made entirely of gunmetal in small sizes, and the scum pipe is bell mouthed. The sole manufacturers are Messrs. Hunt and Mitton, Oozells-street, Birmingham.

LOCAL ANNEALING OF HARD FACED ARMOUR PLATES.*

By Herman N. Lemp, Jun.

Every one is now more or less familiar with the Thomson electric welding process, which in past years has been introduced in almost every metal industry in one shape or another. This process created a new field in the technical application of currents of large volume and small electro-motive force, a field which, while it was primarily intended for welding, naturally suggested a number of other applications to so fertile an inventor as Prof. Thomson; and so it happened that early in its fundamental inception the use of large currents was contemplated to be utilised for heating plain metal bars or parts of sheet billets, &c., for forging purposes, to rivet, upset, to temper or withdraw the temper, or to be worked upon in any well-known manner while being kept heated by current. It has been the good fortune of the writer to lately work out one of these novel applications, and since the literature concerning this branch of electro-technics is somewhat limited, he has thought it advisable to bring an account of the same before the Institute.

One of the latest advances in the making of protective armour for battleships, or even forts, has been the introduction of what is known as the Harvey process. For those not conversant with the latter, I will briefly state that it consists in taking an ordinary low carbon steel plate and introducing an additional percentage of carbon into the surface metal, thus changing the crust to the depth of about an inch into a steel resembling tool steel. A plate thus treated is lastly water-hardened, similarly to an ordinary tool, and by experience has shown to offer, under equal conditions, more resistance to the impact of a projectile than any other armour known. And, therefore, we will take this as an illustration of hard faced armour. The extreme hardness of the surface of a Harvey plate, while exceedingly valuable in preventing projectiles from piercing it, has a disadvantage when it is required to be pierced by a drill and tap. Such holes may be required either for fastening ladders, swivels, or other appliances to the hull of the vessel, or to fasten T flanges supporting the deck to barbettes or turrets.

The methods heretofore used to produce these holes were principally two:—(1) To protect the surface of the plate in patches or strips, to prevent carburation, wherever holes were expected to be drilled; (2) to make accurate drawings and patterns of each plate beforehand, to which all holes are drilled before plate is hardened. Plan No. 1 was practised in the United States until it had to be abandoned. In practice it was found that numerous alterations in construction, errors in either draughting-room or mills, made it necessary to pierce holes where no provisions for annealing were made. It also happened quite frequently that the method for prevention of carburation did not always work satisfactorily, and while white paint indicated well enough where soft metal was expected, very often hard metal was actually found. Hence it was patent from the first that some process was needed to rectify errors of this kind. Experiments were then made with oxyhydrogen blowpipe, or the electric arc, to anneal such spots as were required to be drilled, and numerous mechanical devices for drilling, with drills of every design and method of tempering, were tried, until it seemed that the case was without a remedy. It was at this stage that the problem was referred to the Thomson Electric Welding Company, of Lynn, and experiments were immediately undertaken to solve it. The process and apparatus necessary to carry it out, all resulting from the experiments undertaken, will be described presently.

The second method, which is used in England, has the advantage over the first that there is no difficulty in carrying it out, provided there are no alterations made and no errors committed. The present method of construction seems to be to make beforehand a complete model of the vessel to be built; then make accurate drawings and full-size patterns of every plate, giving the exact location of every hole. These are then bored, tapped and countersunk to a depth of approximately ⅝in., and of a much larger diameter, filled with clay, and then the plate as a whole is heated and hardened with water—see Fig. 1. This method works apparently all right, although in spite of drawings and models errors are made. There is no doubt, however, that it is a slow and very costly method of working, and would hardly ever be resorted to in the United States. From the above it seems clear that there has existed a need for a process by mean of which isolated spots, regardless of location, might be annealed so as to permit drilling and tapping. If, by sending a current of large volume through any spot thus to be treated, the spot is brought to a temperature of, approximately, 1000 deg. Fah., there can be no doubt that the temper has been withdrawn. Experiments carried out to that effect at once showed, however, that upon taking off the heating current the heat was so rapidly conducted away by the surrounding metal masses as to cause the heated spot to become chilled just as effectually as if it had been plunged into cold water. No method of outside protection of the heated spot would prevent this, and the gradual cooling of the spot had to be attained by different means—namely, a gradual and slow withdrawing of the heating current. The method of introducing the annealing current is best shown in Fig. 2. C C are two copper contacts cooled by water circulating inside. The current enters the plate by one end, and leaves it by the other. Right under the contact the metal comes to a bright cherry heat—shown in black—while the portion intervening and partly surrounding the contacts acquires a temperature of just a visible red. Line H H indicates where the influence of the Harvey treatment stops.

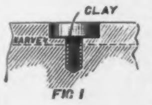


FIG. 1

The shaded portion in Figs. 2 and 3 shows the zone softened and ready to be machined, while the dotted line shows how far the heat radiation would cause the metal to turn blue. When cooled, the annealed portion shows a chocolate colour, while the place where the contacts have been resting is scaled and hard, and cannot be touched by a tool to a depth of about ¼in. These places can again be annealed later on, if required. The apparatus necessary to carry out this process consists of the generator, the annealer proper—transformer—and the regulating apparatus. The generator is commonly a separately excited alternator of variable potential, of a maximum of 300 volts and 100 ampères. The frequency, preferably, should be low, 50 cycles per second being used. When more than one annealer is to be run simultaneously from one generator, constant electro-motive force of the latter should be used, and each annealer regulated separately by a reactive coil. The annealer proper is a transformer similar to the well-known welding transformers. As the apparatus is to be operated outdoors, on board of vessels during construction, it is important that the same may be handled with immunity from electric shocks, even when operated in mist and rain. To meet these conditions a copper-clad type of transformer is used, one in which the secondary is composed of two copper castings, each having a rectangular groove, which two halves, when bolted together, form a closed rectangular frame in which the primary is held enclosed. The hollow space intervening between primary and secondary is, moreover, filled with a heavy oil, which acts both as the insulator and conductor of heat from primary to secondary. The secondary, by completely surrounding the primary, affords an excellent mechanical protection, and prevents electric as well as magnetic leakage. The primary is a copper ribbon insulated with asbestos, and the ratio of conversion is 100 to 1. The transformer has two trunnions fastened to its sides, in a line a little above the centre of gravity, which trunnions swing in bearings, part of a yoke which straddles the whole. The yoke in its turn has a hook which may be secured to the latter at any place of the arch, thus allowing the transformer to be suspended, like a compass in gimbals, in any position desired.

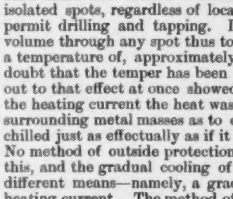

FIG. 2

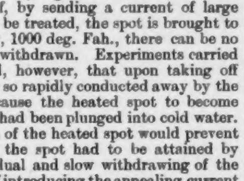

FIG. 3

It goes without saying that the copper castings which compose the secondary are cut through at one place in the circuit. On either side of the cut, two short platforms form the base for copper contacts of various shapes and sizes, by means of which the currents are made to enter and leave the plate to be annealed. These copper contacts are of forged copper, hollowed out to receive water circulation for cooling purposes, and terminate in narrow tips rounded at the end. The weight of the whole annealer, being approximately 1000 lb., is sufficient to give proper contact pressure for all work on a horizontal plate. When inclined surfaces, vertical or otherwise, are to be worked upon, the transformer is suspended so that its weight shall not interfere with the contact pressure, which is obtained for work by bracing the contacts directly with wooden wedges against any object near by. On the outside of a hull it is proposed to use a pair of electro-magnets, which are made to hold themselves against the iron hull, and form a support for the annealer.

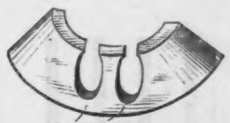

FIG. 4

The remarkable thing is the great amount of current that is being carried by the copper contacts into the plate. The contact surface is seldom more than about ½in. square, and yet 10,000 ampères are made to flow through it continually. This is equivalent to 40,000 ampères per square inch, a density which is only possible on account of the thorough cooling by the water circulation.

The regulating apparatus is in most cases simply a rheostat in series with the field of the generator. When more annealers than one are run simultaneously from one generator, as mentioned before, a reactive coil is interposed between the two, and this latter has been made automatic; that is to say, provided with a dashpot, which permits the current to be reduced uniformly and at any given rate it is set for. This reactive coil is composed of a solenoid coil of cable, well insulated, having a movable laminated iron core which is raised out of the coil by means of a leather strap and winch. The core is composed of thin iron strips placed side by side around a circle, and projecting radially from the same, and being held on top and bottom by a slate disc, in a manner similar to the securing of the copper segments of a commutator. No insulation of the core is necessary, and good ventilation is obtained. The core once raised out of the coil tends to return by gravity and the attraction of the solenoid, but is checked in its descent by a pair of dashpots, one on each side of the coil. These latter communicate with each other, top and bottom, and have one of the pistons provided with a valve which opens when the core is raised, and closes when the core descends. The dashpot cylinders are filled with a light mineral oil, which does not freeze nor clog under any ordinary conditions of temperature. An adjustable by-pass valve allows the oil to flow from the tube to the top side opposite. By opening or closing this valve more or less, any rate of descent, and, consequently, diminution of current, can be uniformly obtained, without requiring any skill on the part of the operator.

The annealing operation is carried out as follows:—The transformer is placed in position, the contacts touching the plate either side of the place marked to be annealed, and the primary current brought up by means of a rheostat to from 75 ampères to 90 ampères for about two minutes, according to the size of spot to be annealed, which will bring the metal to a dull red heat, a temperature at which a pine stick catches fire when held in contact with the plate. If no reactive coil is used, the current is now diminished by turning the rheostat one point every minute. If the reactive coil is used the core is now raised by winch, the coil put in circuit by opening a short-circuiting switch, and then is allowed to descend on its own account. The operation generally takes seven minutes, all told. No difficulty has been experienced from the beginning. The annealing of individual spots was, however, only the stepping-stone to a more important work of a similar nature: work which was about to be given up, owing to what was considered insurmountable difficulties.

In the construction of a modern man-of-war there are many armour plates which act as shields to the guns, and have to be perforated to allow the gun muzzle to pass through and to be either raised or lowered. Some of these shields are circular or oval, with narrow edges around the ports, in the case of Harveyed plate. To perforate these shields after carburation, and before being water-hardened, was the only possible way, since previous experiments had shown that prevention of carburation could not be relied on, and no process was known to anneal the plate locally after hardening. The hardening of a plate once perforated showed itself to be, however, almost impossible; in fact, a matter of chance. In most cases the plate cracked in two—as shown in Fig. 4—or the whole plate became distorted in such a way that it could not be used. As individual spots for holes could be annealed, there could be no doubt that a series of annealed spots could be likewise obtained by the electric process, following a line along which a cutting tool was expected to be run. The first attempt, therefore, and made in England, was to anneal a number of spots in proximity to each other in such a way that the annealed zones should overlap each other.

As described above, it is very important that the temperature of any individual part should be gradually and slowly withdrawn; and while for individual spots the only possible way was to do this by gradually diminishing the current, it was obvious that when a line was to be annealed, instead of annealing a number of spots side by side, the same effect of withdrawing the heat gradually from one portion could be obtained by moving the apparatus itself relatively to the plate to be treated. The rate of this movement, of course, depended upon the rate at which the temperature should be allowed to fall in any particular spot to prevent chilling. The apparatus was therefore arranged to be moved along a line to be annealed, the motion being obtained by an ordinary screw and nut held in a bracket, the nut being turned at a predetermined rate controlled by a watch. It was found that a speed of about ¼in. per minute was sufficiently slow to ensure thorough annealing.

---

* American Institute of Electrical Engineers, New York and Chicago.

The copper contacts were of the simplest kind, as described above, bedding themselves partially in the surface, and when being dragged along by the screw and nut, raised in front of themselves a burr or chip similar to a planing tool. After a whole day's continuous use the copper contacts were found intact, while a number of chips from the steel surface were lying about. We thus had the peculiar phenomenon of a hard steel chip cut with a copper tool.

Upon the completion of the work, it was found that a strip about 2¼in. wide throughout the length over which the machine had been moved could be operated upon by drills or a shaper in a manner as easily as if it had never been hardened before.

In the work just described, the apparatus was moved about, but in regular practice it would be better to construct a machine consisting of a large bed, on which the plate to be treated may be fastened and moved in any direction automatically at a predetermined speed, while the annealer proper is suspended in a given position above plate. The annealing operation occupies but a small percentage of the time required for the cutting.

It is unnecessary to state that when the apparatus is used for continuous annealing, the primary current is kept at a nearly constant value, the diminishing of heat at any individual spot being obtained solely by the moving of the apparatus from it.

As mentioned before, the places where the contacts are passing over the plate, being brought to a higher temperature than any other, remain hard. Experience has demonstrated, however, that they may be re-annealed later on, by treating the spots in the same way as any other hard spot on the plate. By this means we are therefore able to anneal any shaped portions, not merely lines. This is best seen in Fig. 5, in which a series of strips are annealed side by side—shown in shaded lines A. The soft faced surface is then removed on such places by a planer and drill; the machine is then run a second time over the annealed strips, resting it this time on the bottom of the groove and on the softer metal, thus annealing the ridges C left between the annealed strips, on which ridges the contacts were running previously. When all these strips are annealed they may be removed by machine tools without any further difficulty. In a similar manner a large round place may be annealed, as shown by Fig. 6. The transformer is set on the plate, one contact resting on C′, the other at any other place in circle C; the apparatus is then slowly revolved around contact C′ as a centre, until the second contact has completed the circle C. The shaded portion A represents now the annealed surface, which is removed by a cutting tool. The contacts are then made to rest on either side of the centre C′, and the latter is annealed and removed in its turn.

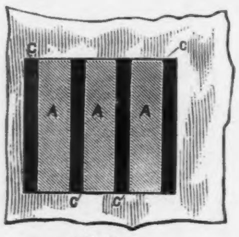

FIG. 5

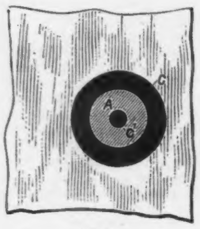

FIG. 6

The apparatus may also be used for the reversal of the annealing process; that is to say, for creating isolated hard spots in soft tool steel by sending a current through the spot to be hardened until it reaches a bright cherry heat, and then suddenly removing the current or machine.

Various other applications will suggest themselves in the operation of this process, already adopted by the United States Government. It may be used in the construction of burglar proof safes, for dies and punches, for projectiles, and other articles of a similar nature.

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Large freight cars.—Most modern freight cars have a weight-carrying capacity of 30 tons, while some cars for coal and ore traffic can carry 40 tons, exclusive of the weight of the car. In a recent discussion on the capacity of cars for general interchange traffic—that is, of traffic hauled over various connecting roads—at a meeting of the New York Railroad Club, a resolution was adopted that cars of over 30 tons capacity should not be built for this class of traffic, but should be confined to local traffic on such roads as desire to use them. This was largely in view of the fact that in ordinary freight service cars are rarely given a full load in each direction, but are often hauled empty in one direction. As to the relative damage to permanent way by engines and cars, Mr. E. E. Russell Tratman pointed out that the intensity and concentration of wheel loads had more to do with such damage than the distributed load of the train, the engine wheels, with three or four driving-wheel loads of 6 to 10 tons on a wheel-base of 12ft. to 20ft., while the car-wheel loads of 4 to 7 tons per wheel are on a total wheel-base of 20ft. to 35ft. Cars of less than 20 tons capacity are not to be accepted for interchange service, as being unfair to the roads owning larger cars. Some large grain cars built by the Northern Pacific Railroad have six sills 5in. by 9in., four 1½in. truss rods below the underframe, riveted steel body bolsters, Fox steel framed bogies, automatic couplers, and air brakes. The dimensions and particulars of these cars are as follows:—

	ft.	in.
Length over end sills	42	0
,, inside	41	0
Width over side sills	9	1
,, inside	8	6
,, over roof	9	11½
Height from sill to roof-plate	7	7
,, rail to side of roof	11	9
,, ,, to top of roof	12	5¼
,, ,, to bottom of sill	2	7¾
,, ,, to c. of coupler	2	10¾
Wheel-base, truck	5	2
,, total	37	0
Body, cross-section	77 sq. ft.	
,, cubic capacity	3157 cu. ft.	
Weight of body	20,000 lb.	
,, of two trucks	12,000 lb.	
,, total	32,000 lb.	
Freight capacity	70,000 lb.	

The Detroit River bridge.—The channel or so-called river which forms the connection between lakes Huron and Erie is a bar to railway traffic, for the elimination of which many plans have been proposed. At the upper end the Grand Trunk Railway on the Canadian side, and the Chicago and Grand Trunk Railway on the American side, are connected by a single track tunnel from Port Huron to Sarnia, but at the lower end the Michigan Central Railroad, the Grand Trunk Railway, and the Canadian Pacific Railway have to carry their trains across on large steam ferry boats, between Windsor on the Canadian side and the important city of Detroit on the American side, a distance of about 2500ft. This ferry system is the source of considerable delay, on account of the lake navigation and of the ice in winter. The largest of these boats is 280ft. long, 45ft. beam, 74½ft. wide over the deck, and 17¼ft. deep. With twenty-one loaded cars on board the draught is 11ft. to 12ft. There are paddles—each worked by an independent engine—and a screw propeller. The bow is formed for breaking the ice. A tunnel was commenced some years ago, but abandoned on account of the peculiarly difficult material, involving great expense. The navigation interests strongly oppose a bridge, but the latest project is for a cantilever bridge with a central span of 1130ft., carried by masonry towers, the shore arms being of 527ft. span, connecting with approach viaducts having lattice deck spans. The headway under the channel span would be 140ft., and the foundation would reach bed rock at about 100ft. below the water, passing through 50ft. to 60ft. of mud, sand, clay, &c. The height from water-line to top of cantilevers over the piers would be about 317ft. The rest piers for the shore arms are on the bulkhead lines. The main channel for the navigation of the larger lake steamers is 35ft. to 50ft. deep. The preliminary plans have been approved by the Chief-of-Engineers, United States Army, and by the Secretary of War.

Sewage pumping plant.—The city of Ithaca is about to put in a duplicate plant for pumping sewage, consisting of two engines, two boilers, and two air compressors, each half of the plant being of the full capacity for the estimated requirements. The pumps, however, are to be arranged so that they can be worked together if required by exceptional circumstances. Each pump is to be of a capacity sufficient to lift the sewage from the screening chamber at the pumping station, raise it to the 14in. discharge main, which is 10,700ft. long, and discharge it into the lake at a rate of at least 1500 gallons per minute. While tenders will be received for any suitable kind of pump, the station is arranged to be equipped with centrifugal pumps, and special excellence in design and guaranted duty will have to be obtained in other designs to ensure favourable consideration. They must deliver the stipulated discharge when running at the most economical speed, and with the sewage 12in. above the suction pipes in the pump well. Steam will be supplied by two boilers. The air compressors will be of a capacity to deliver each 200 cubic feet of free air per minute under a working head of 12 lb. per square inch. Proper means must be provided for priming the pumps and for draining the pump well. The two suction pipes will connect with 12in. pipes at the bottom of the well, and the two discharge pipes must unite before connecting with the 14in. outfall main. The engines are to be fitted with variable cut-off mechanism. The foundations will be of concrete, capped by stone masonry. The duty test will consist of a run of each engine with each boiler for twenty-four hours, or four runs in all, being conducted by one representative of the city, one for the contractor, and a third appointed by these two. For these tests Cumberland bituminous coal at 10s. per ton will be used. Any part found to be defective or overstrained by excessive wear, strain, bad material, or faulty design within the first year of operating must be replaced by the contractor.

Gasoline tramcar.—A self-contained tramcar, operated by a gasoline engine, is now in use at Dayton. It is an ordinary four-wheel car, with vestibuled or enclosed platforms. There are two cylinders, side by side, driving a shaft having a 40in. fly-wheel at each end, these fly-wheels giving a steady motion. Both cranks are in the same plane. On the middle of this shaft is a 12in. friction wheel, 8in. wide. On each axle of the car is hung a frame carrying a friction wheel running on another friction wheel keyed to the axle. For the reverse or backward motion the swinging wheel is brought into direct contact with the friction wheels on the shaft and rear axle, but for the forward motion another small wheel is interposed between the swinging pulley on the front axle and the wheel on the shaft. The swinging frames are operated by screws, the nuts of which are turned by bevel gear on a longitudinal horizontal shaft, the gearing being such that as the forward motion is brought into action the backward motion is thrown out of action. A vertical shaft through the platform, with a crank handle or hand wheel, is used by the driver to regulate the speed and direction of the car. The engine runs continually at unvarying speed. The gasoline is stored in a cylinder tested to 2000 lb. pressure, from which it is admitted to the engine cylinders and exploded by an electric spark from a four-cell battery. The exhaust is discharged through pipes, which in winter pass through the car for heating purposes. A tank is also provided to carry water to cool the cylinder. All the machinery is mounted on the truck frame, thus preventing vibration of the car body.

AUSTRALIAN NOTES.

The drought and hot weather which have been experienced in New South Wales for several months past culminated during the past few weeks in heat waves of an intensity never before experienced throughout the Colony. In the interior the thermometer has stood at over 110 deg. for a fortnight, scorching all vegetation and killing live stock to an extent that will take another season to recover; in fact, in several of the country towns business was at a complete standstill.

The wool season has been successful so far as quality of clip and prices realised are concerned; but, owing to the drought, the clip has fallen short to the extent of about 150,000 bales. The settlement of the tariff in New South Wales has opened up capital, and business shows a better tone than any time during the past year.

A new line of railway has been sanctioned by the Public Works Committee, from Jerildine to Berrigan, the successful tenderers being Smith, Finlayson, and Jones, the price being £19,879.

Walkers, Limited, engineers, Maryborough, Queensland, have secured the contract for the supply of thirty locomotives for the Queensland railways. The contract price is £2390 each. An order for ten more has been placed with the Yorkshire Engineering Company, at, it is stated, £1620 each.

The increase in business in West Australia continues in a marked degree—the revenue returns showing a substantial increase in every branch. For the month of December the principal items were as follows:—

	1895.	1894.
	£	£
Customs	66,423	41,548
Land revenue	19,887	1,670
Mining	7,044	682
Railways	40,815	26,151

The revenue for the year ending December, 1895, being £449,878, showing an increase of £202,814 over the previous year.

The report of the Railway Commissioners of New South Wales for the quarter ending 31st December, state that the earnings show a decrease of £72,263, arising entirely from the effects of the drought. The working expenses for the quarter were reduced to the extent of £22,676, and the percentage of working expenses to revenue stands at the low figure of 47·52 per cent. The figures for the quarter are as follows:—

	£
Gross revenue	870,838
Working expenses	413,865
Net revenue	456,973

A mining conference has been opened by the Minister for Mines in Sydney, and attended by about 300 delegates, who have not yet completed their labours. It is expected that a more complete development of the mineral resources of the Colony will be the outcome of their investigations.

REDUCING JOURNAL-BOX FRICTION.

The resistance of trains to being hauled constitutes the work that locomotives in overcoming it must perform. Any increase in this resistance is a tax upon locomotives, and any decrease in such resistance enables locomotives to perform more useful work—haul more cars or make better time—with the same expenditure of power. It is, therefore, evident that efforts to decrease train resistance are in the line of economy and greater efficiency. Train resistance is really made up of several "resistances," or it has several elements, such as the resistance of the air, the rolling friction of the wheels on the rails, journal-box friction, and the inertia of the load. Probably the most susceptible to reduction of all these is journal-box friction. In cold weather this friction is greatly increased because of the viscosity of the congealed oil. We treated this matter at some length in the last—December, 1895—issue of the *National Car and Locomotive Builder*, and will not go into it again here further than to say that carefully conducted railroad laboratory tests have demonstrated that with a fall of temperature of 70 deg. the friction was doubled with the same oil. Dilution, preferably with kerosene, to a fluid consistency in actual service is the best remedy for this evil.

Our present purpose is to call attention to another possible means of reducing journal-box friction, and this is by giving to new axle-journals a smoother finish than is generally done before they are put in service. Persons familiar with the usual condition of new axle-journals know that they are much less smooth than journals that have seen some service. Actual service gives a smooth, high polish, the equal of which is not even attempted in most shops building new equipment or putting in "new wheels" beneath old equipment. In fact, it is commonly expected that new equipment will have hot axle-journals, and that "new wheels" in old equipment will "run hot." This is principally because of the commonly too rough surface of new journals. There are few more potent causes of train delays than "hot boxes," and in this connection the experience of the Missouri Pacific Railway should be valuable to every person interested in the most efficient operation of rolling equipment. As we announced a year ago, it is the practice of the mechanical department of this road to give a high polish to the journals of all axles and crank pins before they are put in service, and we then illustrated—*National Car and Locomotive Builder*, January, 1895—and described a tempered steel roller of cheap and simple construction used for burnishing the journals. This roller burnisher takes no metal from the journal, but compresses the surface about ·002in., and imparts a harder and smoother finish, and higher gloss than we ever saw imparted by the longest and most successful service. On the road named this method has been found to give the *sine quâ non* for avoiding hot boxes.

Car Work
Swindon

It may be assumed as true that the harder and smoother any two surfaces are, the less will be the amount of friction between them. Watchmakers know that fine steel pivots, running in highly polished holes cut in the hardest jewels, give rise to the least amount of friction, and consequently such surfaces are always chosen for fine watches, as the disturbance of the motion is thus reduced to a minimum. An apparent exception to this is found in the case of Babbitt metal, which is comparatively soft. We do not attempt to offer any explanation of this apparent exception to the general rule—for an exception it certainly is. In selecting the material for axle and crank-pin journals it is important that the material be hard and close-grained. Open-grained surfaces will begin to cut sooner or later, and when once this action fairly sets in it is almost impossible to stop it. Where wrought iron is used, it is important that the fibres of the bar of which the axle is made be thoroughly welded together. If they be left in a loose and fibrous condition, and the direction of the motion be at right angles to the direction in which the fibres run, it will be impossible to produce a smooth-running journal.

One of the greatest benefits conferred upon mechanics by the modern improvements in the manufacture of steel and iron is the introduction of a hard, non-fibrous material for journals. Common steel, good enough for all purposes except the making of fine edge tools, can now be had at a very moderate price, and wherever a journal is required to give the best satisfaction, it should be made of steel. In finishing the surfaces of journals, great care ought to be taken to avoid the use of emery. It is wonderful how readily the hard-cutting grains of emery and similar polishing substances become imbedded in iron, brass, and other materials, and then act just like diamond drills. Every watchmaker knows that a copper wheel or disc smeared with diamond dust will rapidly cut the hardest steel, and the action is the same in regard to all metal surfaces to which emery has been applied with considerable force, as in the ordinary process of polishing. Smoothness is an essential requisite in all surfaces that slide or roll one upon the other, but this smoothness ought in all cases to be attained by burnishing in the manner described, or by cutting with sharp steel tools, and not by polishing with grinding substances.—*The American Engineer.*

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

A meeting of the sub-committee of the Midland Iron and Steel Wages Board was held at Dudley on Tuesday. The certificate of the accountants showed that the average selling price of finished iron for January and February was £5 16s. 8·02d. per ton. In accordance with the sliding scale puddlers' wages will continue at 7s. 3d. per ton, and millmen's wages in proportion, from April 6th to June 6th.

The quarterly meetings will be held next week, and a fair amount of new business is looked for. The works have been finishing old contracts before the Easter Holidays, and business is now practically suspended until these are over. Prices of pig and finished iron are therefore at the moment nominal, but they are slightly weaker than hitherto; though steel is well maintained.

The will of the late Mr. John Lysaght, of Hengrove Hall, Suffolk, and Springfort, Clifton, founder of the firm of John Lysaght—Limited—of the Patent Galvanised Iron Works, of Bristol and Wolverhampton, and head of the firm of Lysaght Brothers and Co., of Sydney, has been proved. It shows personalty to the amount of £424,000, making with other property upwards of half a million. The duty paid on personalty alone reached £32,000. His shares and interest in the business are left to his sons. There are legacies of £250 to several Bristol institutions.

The heavy ironfounders have lately been keeping their men steadily employed, and the producers of all classes of machinery have been fully employed, while the bridge and girder makers have been engaged on some valuable contracts. A considerable amount of work has been turned out by the electrical engineers, who have a great deal of business on their books, and have had recently to keep their men engaged night and day.

A meeting of the General Committee of the Unmarked Bar Association has been held, under the presidency of Mr. S. Hingley. A conversation took place on the present position of trade, and it was reported that all works were well employed, the demand for every description of finished iron was greater, and it was expected that prices would advance in a short time. The chairman said the Association had proved of great service to the trade by assisting in the maintenance of prices, which were relatively higher than formerly.

At the annual meeting of Muntz's Metal Company, at Birmingham, the chairman of the company, Mr. A. Keen, presided; and there were also present Sir H. Wiggin, Bart., deputy chairman; Mr. P. A. Muntz, M.P., Mr. G. Heaton, and Mr. A. W. Marriott, directors; with Mr. R. L. Thompson, general manager; and Mr. W. T. Balcombe, secretary. In moving the adoption of the report and accounts, the chairman said that the shareholders would have observed that the profit for the year amounted to £6767 15s., and, as their reserve fund was created for the purpose of equalising dividends, they proposed to take £4000 from that fund to enable them to pay the same dividend as they paid for 1894, namely, 7½ per cent. The motion was carried unanimously, and a dividend of 7½ per cent. for the half-year on the ordinary shares, making, with the 5 per cent. interim dividend for the first half-year, a 10 per cent. dividend for the year, was declared. Sir H. Wiggin said they had £16,000 left in the bank for equalising dividends, and £55,000 besides. At the time of the great boom in copper the company had large stocks in hand, and this was sold out. The £20,000 extra profits they made that year was invested outside the business, and had remained intact until the present year.

An event of the week is the revolt of a section of the metal trade against the combination for lifting prices and wages, which has been formed in that branch. The dissentients resist a movement which they believe would deprive them of freedom of contract and give a new impulse to foreign competition, and they complain of the form of pressure which is brought to bear on them through their workpeople. With some of the leading and second-class firms in opposition, it will be difficult for the newly founded association to enforce its programme. The German and French competition in sheets, tubes, and wire, has for some time past been very keen. It is now extending to cased tubes, and the German makers of metallic bedsteads, taking advantage of the recent advance in English makers' prices, are reported now to be invading this country. It is understood that a large London house has recently placed an order for 30,000 bedsteads, which will be "made in Germany," with the help, presumably, of Birmingham closed tubes and brass bedstead mounts.

A midland counties district meeting of the Incorporated Association of Municipal and County Engineers was held at King's Heath Institute, on Saturday, there being upwards of a hundred members of the Association present. Mr. T. R. Bayliss—Chairman of the King's Norton Rural District Council—presided at the outset, and welcomed the Association. The president, Mr. E. R. C. Escott, Halifax, thanked Mr. Bayliss, who then vacated the chair. Mr. Robert Godfrey—Kings Heath—read a paper descriptive of fourteen years' work in Kings Norton.

An interesting discussion on motor cars has taken place at a meeting of the Walsall Chamber of Commerce. The president—Mr. E. J. Rhan—said the committee had considered the Locomotives on Roads Bill, and had decided to recommend the chamber to ask that the placing of a light on all vehicles passing along roads be made compulsory, the motor cars to carry a distinguishing light—by preference, red and white; that a speed indicator be attached to every such car, the speed in towns being limited to six miles an hour, and in the country to twelve miles; that bells, or some other similar appliances be placed upon the cars, and that provision be made for the car to be stopped on the appeal of a person riding or driving until he had passed the car. Mr. J. Scott proposed the adoption of these recommendations, arguing in favour of the chamber doing all it could to safeguard riders and drivers, and to protect the interests of Walsall, which were so largely bound up in the continuance of the use of carriages and horses. Mr. Hill seconded the motion. It was useless to attempt to prevent motor cars coming, but they ought to do all they could to make them as safe as possible. Mr. Rathbone thought it would be impossible to stop the motor car, and it was unfair to compare it to the steam car. Mr. Leckie thought the chief objection to the motor car was that it was to be used for the conveyance of heavy traffic. Mr. Hulton proposed as an amendment that the speed suggested should be eight miles for towns and fifteen miles for the country. He thought the benefit that would accrue to the trade of the country at large from the introduction of the motor car would more than counterbalance any harm to the trade of Walsall. Mr. Blyth seconded the amendment, which was agreed to by seven to six.

The remainder of the collieries, machinery, and plant belonging to the New British Iron Company, which is in liquidation, were offered for sale by auction recently at the Queen's Hotel, Birmingham, by Messrs. T. J. Barnett and Son, by order of the Court of Chancery. Mr. W. N. Fisher was present as the receiver and manager of the estate, but there was only a small attendance. The auctioneer—Mr. T. J. Barnett—said that a very large portion of the estate had been realised, and the collieries were practically the remainder of the mineral properties belonging to the estate. The parties interested in the sale were anxious to dispose of the whole of the property as speedily as possible, and the collieries would be sold if there were any reasonable offers for them. The first lot was the Fly and Black Wagon Collieries, in the parish of Rowley, comprising a freehold mineral area of over 66 acres, and a freehold surface area of over 18 acres, with plant, machinery, tramways, and buildings. There was no bidding, and the property was withdrawn. Lot 2 consisted of the Codsall and Bearmore Collieries, embracing a mineral area of 93 acres, and a surface area of 40 acres. The first bid was £1000, and then £1250 was offered. After some persuasion there was a bid of £1500, but beyond that figure nobody was inclined to go, and consequently the property was withdrawn.

The seventh annual dinner in connection with the Birmingham Municipal Technical School Engineering Society has been held recently at the Colonnade Hotel, Councillor Martineau, chairman of the Technical School Committee, presiding. Among those president were Mr. F. C. R. Marks, president of the society; Councillors Howard Lane and Jephcott; Dr. Sumpner, principal of the Technical School; Mr. Mellor, secretary to the Technical School, &c. The chief feature of the after-dinner proceedings was the delivery of a presidential address by Mr. Marks, who said the society had had a very successful session, and was now in a very flourishing condition. Proceeding to deal with various sources of mechanical power, the president predicted that superheating would be again resorted to for the purpose of increasing the efficiency of the steam engine. Numerous forms of energy applicable to practical uses, including gas, water, tidal motion, the wind, electricity, &c., were touched upon by Mr. Marks, who said in conclusion, that whilst heat was the great source of mechanical energy, they had to recognise that our coalfields would not last for ever; there was plenty of energy bottled up in the earth, however, and was it too much to expect that the day would come when means would be found of drawing from that enormous reservoir of heat beneath the comparatively thin crust constituting the earth's surface.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—Just for the present there is very little to really test the actual position of the market, as not only are merchants and consumers for the most part more than fully covered for present requirements, but the holidays act as a further check upon buying, where orders might otherwise be given out. There is consequently a general absence of inquiry, and this tends to give a weakness to prices, as although makers are mostly in a position to hold with tolerable firmness to their full quoted rates, merchants, in many cases, have iron bought which they are compelled to put upon the market, and this is being pushed for sale at very low figures. The position, however, taking it all through, as I have previously reported, continues satisfactory, and temporary fluctuations in prices, or underselling by merchants, have no appreciable effect upon the strong confident tone prevailing with regard to the future.

The Manchester Iron Market on Tuesday was not more than moderately attended, and there was only a slow sort of business doing generally. In pig iron very little business was stirring, and although makers held to late rates, prices in the open market were very irregular. Local and district brands were firm at recent quotations, so far as makers are concerned, but in Lincolnshire iron there were second-hand parcels to be bought at about 6d. under makers' quotations. In outside brands offering here there is some very keen cutting to get hold of business, and for immediate delivery small parcels could be bought at excessively low figures, both in Middlesbrough and Scotch iron. Delivered by rail, Manchester, 46s. 6d. to 47s. are about the average figures for No. 3 foundry, Middlesbrough, and delivered Manchester Docks, orders could be placed at 45s. 3d. to 45s. 6d., net cash; whilst for Eglinton the average quotations, delivered Lancashire ports, are about 47s. 3d. to 47s. 9d., and, delivered Dock Quays, Manchester, 49s. 3d. to 49s. 6d., net prompt cash.

Finished iron meets with a moderate demand, but as regards bars, it is only in exceptional cases where the full quoted list rates are being secured. Delivered Manchester district, £5 10s. represents about the average figure for Lancashire bars, in most cases, with Staffordshire qualities, £5 12s. 6d. to £5 15s.; sheets remain at £7 10s. to £7 12s. 6d., and hoops at £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

In the steel trade, makers of hematites are very firm at their full rates, but merchants would sell at lower figures, ordinary foundry hematites being obtainable through second hands at about 56s. 9d. to 57s., less 2½, with ordinary steel billets about £4 7s. 6d. to £4 10s. net cash, and boiler plates to be bought at £6 5s. to £6 7s. 6d. delivered in this district, although makers nominally hold to £6 10s. per ton.

An active business is reported in the metal market, all descriptions of manufactured goods being in brisk request, and prices well maintained at full late rates, with makers securing on small orders an advance of ⅛d. per pound upon the official list rates for brazed brass and copper tubes.

Throughout the engineering trades of the district new work continues to come forward freely, and generally all the leading establishments are not only fully engaged, but amongst stationary engine builders, machine tool makers, and machinists, there is generally work in hand to keep them going for some time forward. Boilermakers and locomotive builders are now in most cases fully employed, and activity is also reported amongst all the general engineering industries of Lancashire.

I have recently referred in my notes to the activity which has come over the machine tool making trade, and to the very varied class of work that has been given out. As an illustration of what is now going on in some of the principal establishments, a few particulars of a visit I paid to the works of Messrs. Hulse and Co., Salford, will be interesting. I found this firm exceptionally busy with work in progress, principally in connection with special machine tools for dockyard and gun-making operations. Amongst work of the above class were complete plants for the construction of Belleville boilers, and other special tools for Government dockyard and private firms both in this country and abroad, these including special screwing, cutting off, tapping, and facing machines for tubes and junction boxes, and hydraulic presses for staving the tubes. They had also in hand several massive armour plate slotting machines, with universal adjustments for cutting at any required angle, without disturbing the work, and several radial drilling, and boring machines arranged for tapping and studding work, with reversing gear carried on the spindle slide close to the hand of the workman, and with the usual releasing motion to free the spindle and counter-weight to bring it rapidly from the work. Some of these radials are of the box type, with arms to raise and lower upon a sleeve encircling the column, while others have swivelling spindle slides for drilling at an angle. The firm is also engaged in the construction of machines specially designed to deal with stern frames and other large irregular shaped marine castings, these including a horizontal and vertical side planing machine, to plane a height of 6ft. and upwards of 6ft. in length, and a horizontal side planing and shaping machine with 7ft. overhang, which I understand is not only the largest of its class that has so far been made, but possesses a universality of action that has not hitherto been attained. Amongst tools suitable for gunwork were a number of patent vertical milling and profiling machines, whilst the firm had also just finished a large rifling machine, with several new and special features for dealing with guns up to 12in. calibre, and two complete plants for Hotchkiss and Nordenfelt quick-firing guns and ammunition. Messrs. Hulse were also making a horizontal milling machine for locomotive connecting-rods, and universal machines for cutter making and other similar work. The progress of electric driving, I may add, has led the firm to devote special attention to the arrangement of various kinds of machine tools, as well as overhead travelling cranes, with the view of applying motors either direct or otherwise, and they had in hand a number of machine tools specially designed for the above requirements, including large lathes with electric motors, self-contained, with the fast headstock.

Amongst recently designed special tools which Messrs. Hulse and Co. had in hand, there were a couple possessing features of which a rather more detailed description will be interesting. One of these is a universal boring, drilling, tapping, studding, and milling machine, by means of which holes may be drilled, tapped, and fitted with studs over the surface occupied by the largest cylinders, the space commanded being 16ft. long and 10ft. high. The machine has a powerful drilling and boring headstock, made to carry a spindle of from 2½in., which is driven quickly for small work, with double and treble-gear intermediate variations being provided for the different speeds required, whilst it is made to rise and fall on a massive vertical pillar, and to do its work at heights up to 10ft. above the base-plate, or even more if required. The speeds of feed can be varied by means of change wheels, the rising and falling motions being operated by power, with specially arranged slow speeds for use when milling vertically. The vertical pillar itself has the same varied motions by power along a strong side bed, so that its position may be changed rapidly, or it may be traversed to suit the feed required when milling horizontally. When the machine is required for tapping or studding, rebasing and reversing gear is applied to the spindle, and a large grooved base-plate to suit the work in hand, and of any required dimensions, is attached to the machine. The other new tool is an improved band sawing machine, specially designed for dealing with heavy marine work, such as cutting the webs out of large double cranks, or the runner heads off large steel castings, and any other operations of a similar character. This machine, which is throughout of exceptional strength and massiveness, consists of a large baseplate in tee form, the upright of the T carrying the frame which supports the top pulley over which the band saw passes, and the transverse part carrying the beds on which the articles to be cut are traversed. The lower pulley over which the saw passes is secured beneath the baseplate, the pulleys in this machine being 40in. diameter. To keep the saw in tension a balance weight is provided, which acts on the under side of a vertical sliding block carrying the top pulley over which the saw passes. There are two beds on the transverse parts of the baseplate, each of which carries a traversing saddle, actuated together by twin screws, and so arranged that the saw may pass between them. The twin screws are driven through change wheels adjustable on a swing framework, so that any desired traverse may be obtained, and the feed motions give a perfectly steady movement to the traversing saddles. The machine is driven by cone pulleys and the usual driving apparatus, giving several speeds to suit the work under operation.

In the coal trade, except some extra buying to cover requirements during the holiday stoppages of the pits, which will extend over three or four days, there is no material change to notice. All descriptions of round coal continue plentiful, and low in price, especially in the inferior qualities, suitable for steam and forge requirements. With regard to engine fuel, a slight advance has in some few cases been obtained on the better qualities, for forward contracts, but generally prices, although firm at recent quotations, are unaltered. The average quoted rates, with the commencement of the month, are without change, best Wigan Arley remaining at about 10s. to 10s. 6d.; Pemberton, four feet and seconds Arley, 8s. 6d. to 9s.; common house coal, 7s. to 7s. 6d.; steam and forge coals, 6s.; and the better qualities of engine fuel, 4s. 6d. up to 5s.; and common slack, 2s. 9d. to 3s. 3d. per ton, at the pit mouth.

In the shipping trade business shows an improvement, and prices continue extremely low, 7s. to 7s. 3d. being about the average figures for ordinary steam coals, delivered Mersey ports, with as low as 6s. 9d. per ton taken in many cases to move away quantities

Barrow.—The hematite iron trade is still very busy, and makers are sanguine of the continuance of the active market, and are accordingly preparing further to increase the production of iron. At present thirty-nine furnaces are in blast, as compared with twenty-eight in the corresponding week of last year. Stocks are steady at slightly over 303,000 tons. Prices are firm at 50s. for mixed Bessemer numbers, net f.o.b.; while warrant iron is selling at 48s. 4d. net cash, buyers offering 48s. 3½d. In forge and foundry iron business is quiet, but Bessemer is active.

Iron ore is firm in tone, and ordinary sorts are steady at 10s. net at mines, with best descriptions as high as 14s. 6d. Spanish ores, on the other hand, are quoted at 12s. 9d., delivered at West Coast ports. The trade in the latter is growing, and now Spanish ores are largely used for mixing purposes at most of the works in the district.

Steel makers report a very busy state of things in almost every department. Rails are specially brisk, and makers are well sold forward. Ship and boiler plates are also in good demand, and there is much life in the steel casting, billet, and hoop trades, while merchant steel is in growing demand.

Shipbuilders and engineers are very busy, and are expecting some new contracts.

The coal and coke trades are active, and the demand seems to be on the increase. Coal, however, is easy in price, while coke is dearer.

The shipping trade shows increased exports of pig iron and steel, and still further activity is expected in this direction.

The statement is made on the basis of good authority that a new and independent company is about to be formed to erect works at Barrow for the production of heavy armour plates and other classes of shipbuilding material required in Admiralty and commercial tonnage. Attention has been given for some time past to the fact that Barrow is in every sense admirably situated for the successful working of this branch of the steel trade. There is an abundance of rich ores from which the best class of steel can be made, the docks at Barrow will enable makers to deliver cheaply to the dockyards and to the big shipbuilders on the West Coast, and there is also the fact that a large amount of Admiralty work is done at Barrow, assuming at least one good local customer. There are only four works engaged in this trade in the country, and they are exceedingly busy and making big profits. The new company, which is backed with plenty of capital, proposes to draw its supply of metal in a molten state from the furnaces of the Barrow Steel Company. The importance of this new development in Barrow's trade cannot be over-estimated.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THOUGH business is quiet this week, it is not slacker than is usually expected when holiday times intervene; and after the heavy buying that has recently been recorded, a lull is not unwelcome, so as to enable producers to get something like even with their engagements. There is no yielding in prices; in fact, in the lower qualities of Cleveland pig iron, the scarcity of these qualities has led makers to advance them 3d. per ton this week, and now pretty nearly the normal differences between the values of the higher and lower qualities has been re-established. Prices were firmer at the close of March than is usual towards the end of a month, because the makers did not put pressure upon second hands to take deliveries, as they had plenty of orders to deliver without these, and the wharves were quite blocked with steamers awaiting cargoes. A large quantity of iron has recently been sold for delivery to the Continent, and the exports for April are likely to be as satisfactory as those of March have been.

The Cleveland ironmasters' statistics for March are expected to show a decrease of between 2000 or 3000 tons in the stocks of Cleveland pig iron, as compared with an increase of 19,657 tons in February. In Connal's stores at March 31st there were lodged 187,474 tons of Cleveland pig iron, an increase of only 1964 tons during the month, as compared with 4717 tons in February. The hematite trade is evidently not so good as that in ordinary Cleveland iron, for Connal's stock of hematite pig increased 5383 tons during the month, against 3814 tons in February, the quantity being 150,779 tons, and it seems that there is difficulty of getting rid of the hematite iron when once it goes into the stores, as consumers are shy about buying it, seeing that they cannot be sure of the brand they will get

The price of No. 3 Cleveland G.M.B. pig iron in makers' hands has been maintained at 38s. 6d. for prompt f.o.b. delivery, but merchants have been selling at 38s. 4½d., and some odd lots were sold in the last two days of March at 38s. 3d. Practically 38s. 6d. is the figure for April delivery. No. 4 foundry has been advanced to 37s. 9d.; grey forge to 37s. 3d.; mottled to 36s. 9d.; and white to 36s. 3d. Messrs. William Whitwell and Co. have blown out a furnace producing hematite iron, as it needs relining. For mixed numbers hematite pig iron, 46s. 6d. per ton f.o.b. is taken, but several firms hold out for 47s. Rubio ore is 12s. 9d. per ton delivered Tees wharves. There will be no iron market at Middlesbrough next Tuesday.

The sale of the Coatham Ironworks by the National Provincial Bank to a syndicate of local capitalists has been concluded, and the new proprietors will at once proceed to repair them. As the two furnaces, which have been idle for close upon ten years, need relining, it will be several months before they can produce any pig iron. It is stated that the Lord of the Manor has reduced the ground-rent from £400 to £200 per annum, and that the new firm will have better facilities for shipping their iron than the old proprietors had. The furnaces, it is calculated, will require £20,000 spent upon them before they can set to work. Originally the cost was between £60,000 and £70,000, as they were built in 1872, when everything was extremely dear.

On Monday the shareholders of the Teesside Iron and Engineworks Company met at Middlesbrough, and finally confirmed the transfer of the company's property to Sir Christopher Furness, of West Hartlepool

The slag from furnaces producing basic pig iron has long been utilised for manurial purposes, and with excellent results, but the Normanby Ironworks Company has been successful in introducing for similar purposes the slag from its blast furnaces, which are making hematite pig iron. It was first tried last year, and has proved valuable, especially for potatoes, roots, and grass. It contains a large proportion of lime, alumina, and silica, together with sodium chloride. It assists germination to a very great extent.

The finished iron and steel industries show improvement, and prospects are encouraging. It was feared that there might be some interruption to work at the plate and angle mills in this district owing to the dispute in the engineering and shipbuilding industries, where the men claimed advances of wages. Happily the difficulty has been settled in some quarters, and there is every reason to believe that there will be a general settlement on the same lines as have already been agreed to. The engineers originally asked for an immediate advance of 2s. per week on time and 10 per cent. on piecework, and the masters offered 1s. at once and 6d. more in July, but that failing to satisfy the men, the offer was amended and 1s. offered at once, with 1s. more in September, no further change in wages to be made till March next year. To these latter terms the men on Teesside have agreed, and wages have been settled for practically a year to come, which is a great advantage for masters, as well as for the district generally. The West Stockton Ironworks, at Stockton, which made, when in full operation, 1100 tons of plates weekly, and which could readily be converted into sheet mills, were offered for sale by auction a few days ago, but not a single bid was elicited, which is rather strange taking into account the report that one of the leading shipbuilders in the district was reported to be in negotiation for them. Of the twenty workmen's cottages not one was sold.

Platemakers are well supplied with orders, and the price of steel ship plates is maintained at £5 2s. 6d. per ton, less 2½ per cent. f.o.t., while boiler plates are 20s. more, and girder plates 5s. more; there being a very fair demand for the latter, as there is a large amount of bridge building going on, chiefly on export account. Steel ship angles are at £5, iron ship angles at £4 15s., iron ship plates at £5, and common iron bars £5, all less 2½ per cent. and f.o.t. Heavy steel rails are firm at £4 12s. 6d. net at works, and manufacturers have plenty of work on hand; but there seems to be no probability of an early re-opening of the Darlington Steel Works, for on account of their inland situation they—the Darlington Works—cannot compete with the establishments nearer the seaboard. The demand is now mainly for rails for export, and comparatively small quantity being needed by our home railways and in inland works, has very little chance of being successful against the manufacturers having mills near the coast, as they have railway rates to pay on the carriage of their pig iron, or upon the hematite ore if they make their own pig, and then they have to pay railway rates back to the coast of the rails they manufacture. Steel sleepers are in poor request.

The January-February official statistics presented by Mr. Edwin Waterhouse to the Board of Conciliation and Arbitration for the North of England Manufactured Iron Trade, and showing the tonnage of finished iron delivered, and the average net prices realised therefor by the firms in the district, cannot but be regarded as disappointing, seeing that a different state of affairs was expected. It was thought that with the improvement in trade and quotations there would have been a larger production, and a substantial advance in prices, but such has not been the case. The average net realised price of manufactured iron was only 4·2d. per ton better than in the previous two months, and this does not entitle the men to any advance in wages under the sliding scale, as it only brings up the average price to £4 16s. 7·89d., whereas it has to be £4 17s. 6d. before any advance can be given. No change of wages has been made since the end of 1894, when a reduction of 2½ per cent. took place.

It is rather surprising to learn that any description of finished iron realised lower prices than in the previous return; nevertheless, both angles and bars had a lower average, angles by 11·83d. per ton, and bars by 0·79d., but plates went up 9·24d. It is evident that, while manufacturers were quoting higher prices, they have not been in many cases getting them, or they must have had a good many cheap contracts to execute. Iron rails went up 2s. 7·81d., but as out of 20,755 tons made only 491 tons were rails, the advance had little influence in determining the general average price of manufactured. The advance in iron rails is very small compared with that in steel rails. The increase in deliveries is poor—only 448 tons—as compared with November-December. The following is the official record of the deliveries and average net realised prices during the two months ended February 29th:—

Description.	Weight invoiced.				Percentage of total.	Average net selling price per ton.		
	Tons	cwt.	qr.	lb.		£	s.	d.
Rails	491	5	3	19	2·37	4	9	3·93
Plates	7916	3	0	25	38·14	4	13	6·99
Bars	9424	6	0	25	45·40	5	0	5·39
Angles.. ..	2924	1	0	15	14·09	4	14	0·27
	20,755	16	2	0	100·00	4	16	7·89

A special meeting of the shareholders of the Tees-side Iron and Engine Works Co. was held at Middlesbrough on Monday, when the transfer of the company's property to Sir Christopher Furness, of Middlesbrough, was finally confirmed.

The North-Eastern Railway Company has now almost completed the extensive alterations that have been in progress between Gateshead East Station and Pelaw Junction. The railway has practically been doubled—there being four sets of rails over the greater part of the distance, and every bridge from Gateshead to Pelaw has had to be rebuilt. At Pelaw Junction three lines converge, the old Leamside south route, the Sunderland line, and the Jarrow and South Shields line, the first and last approaching by sharp curves. Considerable improvement is being made in the approaches, and a new station is being erected at Pelaw much further to the west than the present structure. Felling station is approaching completion. The company has refrained from demolishing the little stone station-house—the original station of the old Brandling Junction Railway, the earliest line in the district—and is thus a landmark of early railway history. The improvements at Gateshead East Station have had to be curtailed, owing to the opposition of the Corporation, chiefly in regard to the stone bridge crossing High-street. The company desired to carry the proposed extra double line of rails across High-street by means of an iron bridge built alongside the existing stone bridge, but the Corporation insisted upon the demolition of this stone bridge, and the building of a new one, with a single span instead of three—one for the roadway and two for the footways. The company could not come to terms with the Corporation, and so this part of the scheme was abandoned.

The coal trade is beginning to show more satisfactory features; shipments are increasing, as the open weather is allowing of the earlier re-opening of the Baltic ports. Tenders are to be invited shortly for steam coal to be supplied to the Cronstadt Naval Works. The St. Petersburg Gas Company has ordered between 40,000 and 50,000 tons of gas coal, delivery over the season, and the price is 10s. 2d. per ton, c.i.f. Cronstadt. Of the 75,000 tons of gas coal for the Rotterdam Gas Company, two-thirds will be supplied this year from the North of England at 10s. 3d., delivered Rotterdam. Last year only one-third came to this district, the other two-thirds going to German collieries. Coke is very firm at 13s. 6d. to 14s. per ton, delivered at Middlesbrough furnaces.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been very little animation in the Glasgow pig iron warrant market this week. This is due to some extent to the holidays, but, apart from these, the speculative interest in the business has become small. Business was done in Scotch warrants from 46s. 9d. to 46s. 7d. cash, and from 46s. 11d. to 46s. 9½d. one month. The demand for Cleveland warrants was extremely poor, scarcely any business at all being reported at some meetings of the market. The few transactions quoted were at 38s. 6d. to 38s. 3d., one month. Although the current consumption of hematite pig iron is very large, the market for warrants is very dull. A small business was done this week in these at 48s. 3d., cash, and 48s. 6d. to 48s. 5½d. one month. In Scotch-made hematite large deliveries are taking place direct to the works.

The output of ordinary Scotch pig iron has been increased by 300 tons per week. At present the stock in Glasgow warrant stores is increasing about 1000 tons weekly; but the stocks are low, and the prices obtained for sending iron into the store and selling it as warrants are, at current costs of output, quite satisfactory. There are now 43 furnaces producing ordinary, 35 hematite, and three basic pigs, the total number of furnaces in operation being 81, compared with 74 at this time last year.

Prices of makers' special brands of pig iron are fairly steady, as follows:—Govan and Monkland, f.o.b. at Glasgow, Nos. 1, 48s.; No. 3, 46s. 6d.; Carnbroe, No. 1, 48s. 6d.; No. 3, 47s.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, Calder, and Summerlee, Nos. 1, 51s.; No. 3, 48s. 6d.; Coltness, No. 1, 53s. 6d.; No. 3, 49s.; Glengarnock, at Ardrossan, No. 1, 51s.; No. 3, 47s.; Eglinton, No. 1, 48s.; No. 3, 46s.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 52s. 6d.; No. 3, 49s.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

The shipment of pig iron from Scottish ports in the past week amounted to 7438 tons, compared with 7398 in the corresponding week of last year. Of the total there was sent to the United States 70 tons, South America 200, India 294, Australia 20, France 30, Germany 290, Holland 535, Belgium 30, other countries 197, the coastwise shipments being 5552, compared with 5495 in the same week of 1895.

In the malleable iron and steel departments there is continued activity. For finished iron the inquiry is well maintained, but it is scarcely possible to obtain any increase in prices. The steel industry is very busy, the staple work in hand being for the shipbuilding trade. The question of wages in the steel trade has been causing a good deal of anxiety, but it has at length been practically settled, at least for the present, by the Board of Arbitration agreeing that the men shall have an advance of 5 per cent., to begin at once.

There is no real improvement in the condition of the coal trade. The total shipments, taking the clearances at all the ports, are some 4000 tons better than in the preceding week, but this has had no appreciable influence on the state of the market, which as a whole is very dull. Wages are now reduced all over the mining districts, the colliers of Fifeshire having been the last to submit to a reduction of 6d. per day. Inquiries are rather better for shipping coals, and it is now expected that the demand for the Baltic ports will now begin to assert itself. Fair cargoes are being despatched from the West Coast abroad, but the business in the Firth of Forth has been rather restricted. The total coal shipments during the week reached 128,730 tons, compared with 124,164 in the preceding week, and 123,516 in the corresponding week of last year. The prices f.o.b. at Glasgow are:—Main coal, 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 6d. to 6s. 9d.; and steam, 7s. 6d. per ton. These rates are in some cases quite nominal.

During March there was launched from the Clyde shipyards 25 new vessels with a total tonnage of 41,086, compared with 22 vessels and 24,755 tons in the same month of last year. The output of the three months comprised 49 vessels of 94,299 tons, against 48 vessels of 61,249 tons in the first quarter of 1895. It is estimated that the new orders placed in the course of the month amount to 44,000 tons, compared with 30,000 in March last year.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

IT has been strongly enforced in this column of late with respect to the discharge note, that, as a prudential measure, it would be wise to suspend the operation of the note and thus give time for reconsideration and, if imperative, for the formulation of a substitute. I am glad to state that the suggestion, which has been reiterated several times, for the urgency was so palpable, was adopted on Saturday last by the Coalowners' Association, and ratified by the Sliding Scale Committee. The threatened strike has now been averted, and only just in time. On Saturday the men's representative, who met the Sliding Scale Committee in Cardiff, would hear of nothing until the note, difficulty was settled one way or the other, and had the coalowners been as decided, the order would have gone forth, I am informed, for a general strike. It would be well now for the belligerents to cool down a little, and then will be the time to see how far the contention is true, that the introduction of the note was a violation of the sliding scale, and also to arrange, by the collective wisdom of the joint representatives, a sufficient distinction between the industrious and the irregular workmen. One of the contentions of even loyal colliers is that, granting the note to be sound in principle, it was abused, and it gave power into undeserving hands to oppress colliers with whom they were in disagreement.

The Plymouth colliers are now making up for their long holiday, and are busily working, though it will be a long time before all the working places are filled. It is a tribute to the management that no disaster has happened so far, showing that every care was taken in looking after ventilation, &c. These collieries are better equipped with electric appliances than any other I know in Wales, and this, though costly, must pay in the end. The coal audit, Saturday, declared no change in wages.

The coal trade last week was quieter than expected. Probably the rush for clearances will be this week. Since my last there have been some noticeable shipments, Port Said taking the chief in tonnage of 5200 tons, 3000, 3800, and 3500 tons. Several important ones have been sent to Cape Town, Buenos Ayres, and Genoa, and one fine one of 4601 tons to Kurrachee. Coalowners are quite aware that the war feeling has not all blown away, and coaling stations will be well looked after for some time to come. Swansea and Newport, Mon., coal shipments have been slightly below the average. As regards Monmouthshire coal for Cardiff shipments, it was remarked on 'Change, Saturday, that the market was in a drooping condition. Best Western Valleys were quoted at 8s. 3d. to 8s. 6d., and Eastern Valley coal 7s. 3d. to 8s. This week, 'Change, Cardiff, has been well attended, and much more animation shown. Inquiries for best and seconds have increased. Dry coals remain flat. Best small is improving. Latest prices were: Best steam, 10s. 3d. to 10s. 6d.; best seconds, 9s. 9d. to 10s.; ordinary seconds, 9s. 3d. to 9s. 6d.; drys, 8s. 9d. to 9s. 3d.; best Monmouthshire, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; best small steam, 4s. 9d. to 5s.; seconds, best, 4s. 3d. to 4s. 6d.; drys and other inferior sorts, 3s. 6d. to 3s. 9d.

There is no change for the better in the house coal trade, and it was currently reported on 'Change, Cardiff, this week, that the supply of No. 2 Rhondda was so much in excess of requirement, that some owners are considering the advisability of limiting output. Prices, maintained with difficulty, are:—Best, 10s. 3d. to 10s. 6d.; No. 3 Rhondda, 9s. 6d. to 9s. 7½d.; brush, 7s. 6d. to 7s. 9d.; small, 6s. to 6s. 3d., No. 2, Rhondda, 7s. 3d. to 7s. 6d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d., Cardiff. Coke continues in a vigorous condition; furnace, 13s. to 15s.; foundry, 15s. 6d. to 16s. 6d.; special foundry, 19s. to 20s.

Pitwood is in better demand, and stocks are moving more quickly, but being heavy, prices remain 14s. 9d. to 15s., Cardiff.

Patent fuel is moderately active, Swansea and Cardiff. Disposition of buyers is not to give full quoted prices. Swansea unchanged, Cardiff ranging from 10s. to 10s. 3d. inferior, and 10s. 4½d. to 10s. 6d. best. Swansea export last week 3259 tons, Italy taking 2434 tons.

Pig iron warrants are declining slightly, and a revival is not expected for a few weeks. Generally, quotations iron and steel and tin-plate remain as last week. Iron ore prices are also the same, Rubio, 11s. 6d. to 11s. 9d.; Garucha, 10s. 9d. to 11s.; Tafna, 11s. 3d., c.i.f., Cardiff. Only a few cargoes have come in this week, principally to Cyfarthfa, Dowlais, and Société Commerciale.

The tin bar trade is deplorably bad, and as prospects ahead are anything but encouraging, at all events for some time, I am not surprised to note certain changes going on in leading steel works for improved plant, &c., for steel rails. Works which for a long period, especially during the prosperous days of tin bars, had ignored steel rails altogether, and others only made colliery sections, are now preparing to pay more attention to the rail branch, and there is just a possibility that they may reap the reward of their foresight. Swansea Exchange report is that the demand for tin bars has fallen off appreciably, and fewer inquiries are reported for other local makes. Steel rails are in good demand, although this branch of the steel trade is keenly competed for by foreign producers.

The shipments of tin-plate from Swansea last week amounted to 43,797 boxes, receipt from works 29,375 boxes, thus reducing stock a little more than usual, though not enough to improve the condition of things. Stocks now amount to 161,995 boxes, as compared with 176,417 boxes this time last week, and 182,424 boxes contrasted with the corresponding period of 1895.

In the Briton Ferry district, which, through good and ill report, has maintained a hopeful condition, I am assured that the outlook for the immediate future is bad. This week notices were posted at the Vernon Tin-plate Works to terminate all contracts with the workmen. The mills at the Baglan and Earlswood Tin-plate Works have been fully occupied. At the former the 1874 list is rigidly adhered to. An average make of pig iron at the Briton Ferry works, and of ingots and steel bar at the steel works, is reported.

Liverpool reports that some tin-plate business has been done in Wales at 8s. 10½d. to 9s. 3d., and Siemens from 9s. to 9s. 9d.

A serious colliery explosion occurred on Saturday at Meiros, near Llantrissaint, one man being killed on the spot, and ten others more or less severely burnt. It appears that the pit is considered so safe as to be worked in part with naked lights. The down cast is only 80 yards, output 500 tons per day, and average number of men employed 250. The explosion is attributed to a sudden discharge of gas from a "blower."

I am glad to see that the Cambrian Railway is the first in the field with a reduction of first-class fares. The Cambrian and the Brecon have a fine season ahead of them in connection with North Wales, the installation at Aberystwith, and the Eisteddford at Llandudno.

The Workmen's Tin-plate Union is to meet shortly. Fairwood men, Gowerton, have conceded 15 per cent. and resumed work.

Sir W. T. Lewis, Bart., has left for the Continent. The testimonial movement at Aberdare is well advanced and another in the Rhondda is progressing, but the chief recognition of his baronetcy is at Merthyr, the proposal being to erect a statue, and to this I hear subscribers are sending in from all parts of the country.

Mr. H. W. Lewis, J.P., C.C., C.E., identified with the mechanical engineering progress of the mining district, has left for Madeira on account of ill health. It should not be forgotten that Mr. Lewis was one of the rescuers at Tynewydd, and obtained the medal for valour.

3500 colliers are in disagreement at Tredegar, on account of refusing to use boxes for slag; only a temporary stop is apprehended, though the colliers have shown a strong reluctance to give in to the request of the management. It should be admitted at once by them that coal despatched with a quantity of slag tells badly in the market. At some collieries I have seen the utmost care shown in clearing off slag, and men employed on the wagon for a final clearance before the coal train is despatched.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

REPORTS from the different iron-producing districts testify to a very lively trade. The steady rise in quotations that has been going on ever since the beginning of the present year has led to the belief that purchasers will not derive any advantage by waiting, but, on the contrary, are likely to have to pay more; a disposition to buy without delay is, therefore, noticeable, the more so as an active spring trade is promised. In the building line considerable animation is already to be perceived, owing to the singularly mild weather which we have had this month.

The Silesian iron market is steady, and there is a good demand experienced in all departments. Pig iron sells briskly at fairly remunerative prices. The finished iron and steel works are also well employed, the number of contracts increasing from week to week. From the coal district of Silesia pretty favourable accounts are being received, and summer quotations, which have recently been fixed, will be 2 pf. to 4 pf. p.t. higher than those of last year.

The week commenced favourably on the Austro-Hungarian iron market. Bars, which have been in extremely good request, were raised 25 to 50 cr. per 100 kilos., and a further advance is likely to take place next month. The blast furnace works are in fairly regular employment, though, on the whole, but few large orders have been placed recently. The strike of the colliers in Moravia is ending as usual, the majority of the men returning to their work. Only from some parts of Austrian Silesia unfavourable reports are being received, no less than 8000 colliers having put down work. Up to the present the loss in wages amounts to about 300,000 fl., while for coal, which on account of the strike had to be imported from abroad, nearly 1,000,000 fl. were paid.

The tone of the French iron trade has, of late, been extremely firm. There is an upward movement noticeable in all departments. The demand that is coming in on home account is sufficient to secure regular employment to the works for some time, and there are also some fair export orders holding out. The convention of the plate mills has been prolonged till end of 1901. Axles recently met with an advance of 2f. per 100 kilos. In the Ardennes there is a decided upward tendency to be noticed; steel was advanced 10f. p.t.

In Belgium the demand for nearly all sorts of iron and steel is strong, and the raised quotations are willingly paid. Foundry pig is in particularly good call. Among the different articles of manufactured iron, bars and plates are, perhaps, those that meet with the most active request; for the last named article an advance of 0·25f. p.t. has been agreed upon, iron plates, No. 2, now standing on 137·50f. p.t. Steel plates fetch 147·50f. p.t. The Belgian coal market has been showing a slightly weakening tendency of late, but there is still a fair number of orders coming in. Until now the colliers' strikes have, fortunately, had but little influence on the Belgian coal trade in general. On March 31st tenderings for the supply of 520,000 t. coal for the State railways will be received at Liège and Charleroi.

During the week now past the business in iron and steel has been exceptionally brisk on the Rhenish-Westphalian iron market, spring demand being strong. Stocks are decreasing rapidly. Prices continue to improve, and consumers are really anxious to purchase largely, as there is every cause to expect a further rise in next quarter. With regard to iron ore, quite favourable accounts have been received upon the week. Siegerland sorts are very brisk of sale, and the Nassau ore mines have likewise secured some rather heavy contracts lately, in spite of the keen competition from Spain, Sweden, and Luxemburg. The prices quoted last week were for spathose iron ore, M. 9·10 to 9·60 p.t.; roasted do., M. 12·70 to 13·40 p.t.; calcined iron ore, M. 12 to 14 p.t.; inferior sorts fetching M. 10 to 11 p.t. For Nassau red iron ore, 50 p.c. contents, M. 9·30 p.t. is given. The trade in Luxemburg-Lorraine minette is a fairly good one, prices for the different sorts ranging between M. 2·40, 2·60, and 3·20 p.t., according to quality.

Inland as well as foreign demand for pig iron has been exceedingly brisk of late, and the number of orders that are booked increases from week to week. This has naturally had a good effect on prices, and list rates are on an average 2 to 4 marks per ton higher than a fortnight ago. Spiegeleisen, 10 to 12 p.c. grade, is sold at M. 58 to 59 p.t. Forge pig, No. 1, M. 53 to 55 p.t.; No. 2, M. 42 p.t.; hematite, M. 65 p.t. Foundry pig, No. 1, M. 65; No. 3, M. 57 p.t., free at works. Basic, M. 54 to 56 p.t.; German Bessemer, M. 60 p.t.; Luxemburg forge pig, 56f. p.t., free Luxemburg. The malleable iron trade is very busy. Bars are experiencing a good demand, and prices continue to improve. For the present, however, makers are gaining but little.

A very active inquiry is coming in for girders; hoops also show some improvement. The plate mills are reported to be steadily occupied; sheets also continue in very good call. A somewhat improving report is generally given of the activity in the wire and rivet business, but prices remain poor. Machine and construction shops are, as a rule, in satisfactory employment; the same can be told of the foundries.

Present list rates, per ton at works, are as under:—Good merchant bars, M. 116 to 118; rivet iron, M. 135; angles, M. 125; girders, M. 92 to 95; hoops, M. 123 to 125; billets in basic and Bessemer, M. 84 to 85; heavy plates for boiler-making purposes, M. 160; tank ditto, M. 135 to 140; steel plates, M. 130 to 135; tank ditto, M. 120; sheets, M. 145 to 155; iron wire rods, common quality, M. 125; drawn wire in iron or steel, M. 120 to 135; wire nails, M. 127 to 130; rivets, M. 170; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 200; steel rails, M. 108 to 110; steel sleepers, M. 106; fish-plates, M. 112 to 120; light section rails, M. 98.

LAUNCHES AND TRIAL TRIPS.

On the 30th ult. Messrs. Ropner and Son, of Stockton-on-Tees, launched a steel screw steamer of the following dimensions, viz:—Length between perpendiculars, 290ft.; breadth, extreme, 43ft.; moulded depth, 19ft. 9in., which they have built for Mr. Christian Klaveness, of Christiania. The vessel is built on the part awning decked rule, with poop and raised quarter deck, her deadweight carrying capacity being 3500 tons on 18¼ft. The saloon and cabins for captain and officers are fitted in the poop, the engineers' accommodation being amidships. She is built on the web frame principle, leaving the holds entirely clear for cargo, and carries her water ballast in a cellular bottom and in the after peak. All labour-saving appliances are fitted for the economical working of the steamer, and also for the expeditious loading and unloading of cargoes. She has steam steering gear amidship and screw gear aft, four powerful steam winches, a large multitubular donkey boiler, direct steam windlass, stockless anchors, &c. The engines will work up to about 900 effective horse-power, and are by Messrs. Blair and Co., having cylinders 21½in., 35½in., and 58½in. by 39in. stroke, steam being supplied by two large steel boilers working at 160 lb. pressure. The name of Laurelwood was given to her as she left the ways.

On Thursday, March 26th, the new steel screw steamer Lorle, recently launched by Messrs. Irvine and Co., of West Hartlepool, proceeded on her trial trip. She is the fourth vessel built by this firm for Messrs. Trechmann Brothers, of West Hartlepool. A large party were on board, amongst whom were Messrs. Otto Trechmann and Albert Trechmann, who represented the owners; Captain Ben Murrell and Mr. Maddison, who superintended the building of hull and machinery; Messrs. R. Coulson and E. F. Irvine, representing the builders; and Mr. Corking, the engine builders. Her dimensions are 314ft. by 44ft. by 23ft. 3in., with a gross tonnage of 2685 tons, and has been built to Lloyd's highest class. Her deck erections consist of poop, bridge, and topgallant forecastle. The saloon and cabins for captain and officers are fitted up in poop, engineers being berthed under bridge deck at sides of engine-room, and crew in topgallant forecastle. A cellular double bottom extends fore and aft for water ballast. In order to provide for rapid loading and discharging, four powerful steam winches by Irvine and Co. have been placed at hatchways, with double derricks to suit. Steam steering gear amidships, screw gear aft; two large donkey boilers and direct steam windlass. Boats are placed on beams overhead. Triple-expansion engines by Messrs. Blair and Co., Stockton-on-Tees, have been fitted; cylinders, 23in., 37½in., and 61½in. by 39in. stroke. After cruising about for some time for adjusting compasses, the vessel's speed was tested, when an average of 12 knots was obtained. The vessel then proceeded to Cardiff, under the command of Captain Grahl, to load for her maiden voyage.

On Saturday, March 28th, Messrs. Wigham Richardson and Co. launched from their Neptune Shipyard a steel screw steamer which they are constructing for the well-known Rickmers Company, of Bremen, built of steel on the web frame principle, 427ft. in length, 50½ft. beam, and 30ft. in depth, and carrying about 7200 tons deadweight of cargo on a moderate draught of water, and, being intended for the Eastern trades, she is fitted with every accommodation for a limited number of passengers in the citadel amidships. The arrangements for loading and for discharging cargo are very extensive, and with other appliances include eight steam winches as well as various other steam deck gear, &c. Unlike other vessels of her class, the Elizabeth Rickmers is built with a clipper bow and a female figure by Allan, which it is hoped will satisfy the artistic feelings of her owners, who are well known in Germany as patrons of art, and whose residence at Vahr contains Fitger's frescoes of the "Midsummer Night's Dream." She will be rigged as a two-masted schooner, and her lower masts will be of such a length that she can go up the Manchester Ship Canal in ballast. The propelling machinery is of the quadruple expansion type, working at 215 lb. pressure, and self-balanced according to the Yarrow, Schlick, and Tweedy system, and is also being constructed by Messrs. Wigham Richardson and Co. Quadruple engines balanced according to this system are now becoming well known and extensively used, not only because of the saving in fuel, but also on account of the entire absence of vibration at whatever speed the engines may be running. It has been found that the consumption of fuel is from 10 to 15 per cent. less with this type of engine than with ordinary triple engines working at 160 lb. pressure. The builders have several more sets of balanced engines in course of construction for steamers for various purposes, though this is the only steamer hitherto acquired by the Rickmers Company which is fitted with them. The launch was witnessed by a goodly number of visitors, including Mrs. R. Spence Watson and the Misses Spence Watson, Mr. Charles J. and Miss Spence, Mr. and Mrs. F. W. Dendy, Mr. and Mrs. Christie, Mr. Wigham Richardson, Mr. J. Tweedy, Miss Dupré, Miss Roberts, Miss Moffatt, Mr. Frank Richardson, Mr. Burland, Mr. and Mrs. Frank Christie, Mr. R. H. Winstanley, Mr. E. P. Sturge, Mr. G. Glover, and Mr. A. Heine, of Bremen, under whose superintendence the steamer is being constructed. The vessel was named by Miss Mary Spence Watson, daughter of Mr. R. Spence Watson, of Bensham Grove.

The s.s. Algoa, which has been built and engined by Messrs. William Doxford and Sons, Pallion, left the Wear on the 26th ult. for her official trial trip, after which she proceeded direct to Cardiff. She has been built to the order of Messrs. Crow, Rudolf, and Co., Liverpool, and at this date is the largest cargo vessel yet built in Great Britain, her deadweight capacity being 11,375 tons. The dimensions over all are 465ft. by 58ft. by 35ft., and load draught 26ft. She has tri-compound engines of 29in., 50in., and 80in., by 51in., with two single-ended boilers fitted with Brown's induced draught and Serve tubes, enabling the vessel to steam fully 10½ knots when loaded. She is exceptionally well provided with discharging gear, being fitted with eighteen cargo derricks, all of which are carried on side posts so as to shorten the radius of the derricks necessary to put the cargo clear over the side. This is an arrangement which was originally adopted by Messrs. Doxford in the large steamer built by them for the British-India Steam Navigation Company in 1890. These posts are fitted vertical with the keel-line, enabling the derricks to be easily moved either in or out, saving a large amount of labour which is usual in the ordinary arrangement of derricks on raked masts. There are nine horizontal steam winches by Messrs. Clarke, Chapman, and Co., fitted so that each winch works two of the derricks. The steering arrangement adopted is that of Messrs. Fawcett, Preston, and Co., of Liverpool, in which hydraulic power is used, and from experience already gained has been found particularly economical in steam consumption, as the motive power—that is, the hydraulic pumps—are fitted in the engine-room, in close proximity to the boilers; the controlling wheel for these pumps being fitted on the bridge amidships. In addition to this the vessel is fitted with Harfield's compensating hand gear. The anchor gear is also of an exceptional nature, consisting of two independent steam windlasses, by Messrs. Clarke, Chapman, and Co., with vertical engines, each operating independently one of the cables, and also one steel wire mooring rope, each having its own independent brake and clutch gear. The vessel is also fitted throughout with electric light on Messrs. Clarke Chapman's system, with four large deck clusters for cargo working, and the usual arrangement of lighting throughout engine and boiler spaces, cabins, holds, &c. On the trial trip, after the adjustment of compasses, the vessel was run at full speed, when a record of about 11½ knots was shown. This vessel has been built throughout under the superintendence of Mr. F. J. Pilcher, of Liverpool, representing the owners.

Last week the new steamer Balmoral, built by C. S. Swan and Hunter, Wallsend-on-Tyne, for Messrs. Raeburn and Verel, of Glasgow, was taken to sea for her trial trip. The Balmoral is a finely modelled high powered spar deck steamer 380ft. long over all, by 46ft. beam, by 30ft. 3in. moulded depth, and has been constructed with a long poop, long bridge amidships, and topgallant forecastle, giving her a large cubic capacity for Eastern trades. She has been fitted on all the latest ideas for the rapid handling of cargo; and for the convenience of trading in different ports, is sub-divided, not only with the usual bulkheads, but also with extra high 'tween decks. The machinery has been constructed by Mr. Geo. Clark, of Sunderland, and consists of a set of engines 26in., 42in. and 69in. diameter by 48in. stroke, supplied with steam by two large single-ended boilers fitted with Howden's system of forced draught; and in order to meet the requirements of various ports, the hull and engines and boilers have been constructed, not only to pass Lloyd's survey, but also those of the British Corporation, Board of Trade, and the German law. The weather being somewhat stormy and thick, it was impossible to run the measured mile. The steamer therefore headed direct for Middlesbrough, and steamed to her destination at a mean rate of about 12½ knots, and was moored safely at the Redcar wharf, where she took in part of her cargo of pig iron, proceeding afterwards to Middlesbrough docks for bunkers, after which she steamed over to Antwerp to complete her loading for Japan, the vessel having been chartered by the owners to the Nippon Yusen Kabushiki Kwaish, Tokio, Japan, for their line of steamers between Europe and Japan. At the trial trip the managing owners were represented by Mr. William Raeburn, and Mr. William Thomson, the superintendent; the builders by Mr. Rowland Hodge, and the engine builders by Mr. John Clark. In the course of a few remarks which were made after luncheon, Mr. Raeburn took the opportunity of observing that he had in recent years been carefully considering the question relating to the model and power of what are usually known as "Tramp steamers," and he had come to the conclusion that in order to compete successfully with other firms it was necessary to have vessels which should not be too full, and should not be too slow, and with this object in view, all their recent steamers, such as the Osborne and Linlithgow, and in the present case the Balmoral, had been built on fine lines and with good power, so that, if necessary, the steamers could be propelled economically at a fair rate of speed, and thus be in a position to obtain the top freights which were available.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

18th March, 1896.

5995. Pneumatic Tires for Cycles, &c., J. Watt, Glasgow.
5996. Spraying Machines, G. F. Strawson, London.
5997. Apparatus for Collection of Card, &c., J. Partington, London.
5998. Thread Bobbin Holder, A. Brown Glasgow.
5999. Roller Letter Copiers, E. E. Young, London.
6000. Advertising, A. J. Pheazey, London.
6001. New Form of Vacuum Tube, H. C. Newton, London.
6002. Chain Wheel, J. Hollis, Ilkeston.
6003. Brakework for Cycles, J. Hollis, Ilkeston.
6004. Detachable Pneumatic Tire, J. Hollis, Ilkeston.
6005. Making Pipe Joints, J. Wood and W. Clark, London.
6006. Strong's Patent, E. G. Strong, Cardiff.
6007. Printing, J. E. Thornton, Altrincham.
6008. Apparatus for Evaporating Liquids, F. S. Cripps, Surrey.
6009. Composition of Furnace Bottoms, J. Hill, Stockton-on-Tees.
6010. Pocket to Fit in Tubes of Cycles, A. E. Hall and J. W. Sadler, York.
6011. Automatically Closing Water-tight Doors, W. O'Brien, Glasgow.
6012. Diminishing the Risk of Kitchen Boiler Explosions, G. Pinnington, Chester.
6013. Door Curtain-rods, T. Pursey, Edinburgh.
6014. Beating Engines for Paper Pulp, J. Shaw, Halifax.
6015. Waste Water-closets, J. J. Green and W. Oates, Halifax.
6016. Grooved Collars for Ships' Lamps, J. and W. Hayes, South Wales.
6017. Combination Furniture, J. Mather, jun., Glasgow.
6018. Lubricator Expeditor, J. T. Thornton, Huddersfield.
6019. Food Preparations, D. Horn, London.
6020. Combination Spools for Cotton, &c., H. and A. White, Derbyshire.
6021. Fire-grates, T. Hill, Hull.
6022. Brake for Road Vehicles, W. Hawley, Sheffield.
6023. Heating Feed-water for Engines, F. Wilson, Sheffield.
6024. Cylinder Friction Clutch or Grip, W. L. Preece, Derby.
6025. Penholders, J. Bader, London.
6026. Basins, W. C. Ramshaw, Bradford.
6027. Brakes for Velocipedes, W. Bratby, jun., Manchester.
6028. Kiers for Bleaching Fabrics, E. Deakin, Manchester.
6029. Valve Gear of Fluid-pressure Engines, J. W. Melling, Manchester.
6030. Applying Wheels for Skating, H. and J. Thomson, Huntingdonshire.
6031. Shelf Tidy for Libraries, A. Lewis, Leominster.
6032. Umbrellas, W. S. S. Fleming, Glasgow.
6033. Aluminium Alloys, W. Pearson and J. A. Bott, Birmingham.
6034. Appliances for Buckles, &c., G. Brazenor, Worcestershire.
6035. Hinges for Oven Doors, &c., A. Chatwin, Birmingham.
6036. Elevators, J. F. Fitchett and F. Fitchett, Birmingham.
6037. Stocking-knitting Machines, F. B. Salzer, London.
6038. Securing Tarpaulins to Hatches of Ships, J. R. Watson, London.
6039. Lamp for Cycles, J. Jelinek, London.
6040. Oil Cooking Stoves, F. S. Rippingille, London.
6041. Water Filters, F. H. Eydman, London.
6042. Combined Weighing Machine, &c., H. Davies, Cardiff.
6043. Stands for Exhibition of Eggs, &c., W. Fowler, London.
6044. Buckles for Harness, T. E. Williams, London.
6045. Bolts, W. Keen, London.
6046. Gear for Cycles, E. Schebesta and E. S. E. von Linderstamm, London.
6047. Extension Crank, R. Wilcox and D. V. Eskell, London.
6048. Controllers, J. Devonshire.-(*W. B. Potter, United States.*)
6049. Machines for Cleaning Knives, J. G. Pike, Norwich.
6050. Weighing Instruments, &c., A. Finney, Glasgow.
6051. Stitched Leather Belting, &c., G. Hurn, London.
6052. Igniting Compound for Matches, G. Schwiening, London.
6053. Primers for Firing Guns, The Morris Tube Ammunition and Safety Range Co., C. Cuthbertson and W. H. Stentiford, London.
6054. Diminishing Visible Smoke, E. E. Dulier, London.
6055. Regenerative Gas Lamps, G. Bower, London.
6056. Handle Bars for Velocipedes, J. F. O'Brien, London.
6057. Billiard and other Cues and Tips, H. Misener, London.
6058. Electric Incandescent Lamps, G. Bamberg, London.
6059. Gear Cases, H. Fearncombe and Co., and A. Evans, London.
6060. Lubricators, W. P. Thompson.—(*S. Bernstein, Germany.*)
6061. Pen, E. Herrmann, London.
6062. Cycle Driving Gear, W. Reilly and C. Haigh, Manchester.
6063. Appliance for Govening Horses, J. N. Beevor, Birmingham.
6064. Apparatus for Washing Bottles, W. Smith, Liverpool.
6065. Bedsteads, F. Wood, Liverpool.
6066. Washing and Cleansing Sand, J. Arnold, Birmingham.
6067. Gas and Oil Engines, &c., F. H. Briggs, Liverpool.
6068. Spindles and Knobs for Locks, J. Masters, London.
6069. Electrically Coating Wire, W. S. Rawson, London.
6070. Cocks and Valves, J. Ascough and H. C. Fowler, London.
6071. Primary Electric Batteries, W. Rowbotham, London.
6072. Pneumatic Tires for Cycles, F. E. V. Taylor, London.
6073. Production of Motive Power, D. Cook, London.
6074. Improved Sewing Machine, H. Manning, London.
6075. Photographic Apparatus, B. J. B. Mills.—(*C. Chorretier, France.*)
6076. Water-closets, J. Jones and S. H. Rowley, London.
6077. Manufacture of Armour Plates, J. H. Dickenson and E. M. Fox, London.
6078. Cycles, K. Klose, London.
6079. Envelope for Use with Letters, H. Southey, London.
6080. Compound Steam Engines, T. G. Clayton, London.
6081. Fastening Tobacco Pouches, W. W. Reed, London.
6082. Tin Plate and Spike Lock, A. S. Hardman, London.
6083. Mucilage Bottles, W. T. Williams, London.
6084. Yachts, D. McLean, London.
6085. Swings, S. W. White, London.
6086. Attachment for Stoves, W. Laubersheimer, London.
6087. Car Fenders, N. Leccese, London.
6088. Hat Pins, M. H. Coltharp and W. L. Dorram, London.
6089. Game Devices, R. W. Tunstall, London.
6090. Cycle Bells, C. V. Zinn, London.
6091. Fish Traps or Hooks, A. W. Phillips, London.
6092. Manufacturing Cardboard, A. J. Boult.—(*C. David and Sohn, Austria.*)
6093. Manufacture of Boots, &c., J. E. Leavesley, London.
6094. Tongs for Suspending Articles, A. J. Boult.—(*D. J. Aubert*, ——.)
6095. Water-tube Boilers, W. H. Wilson, London.
6096. Aluminate of Barium, &c., D. A. Péniakoff, London.
6097. Stop Valves, F. N. Mackay, London.
6098. Cycles, B. Lefebure, London.
6099. Manufacturing Hollow-ware, W. L. Wise.—(*La Società Italiana per la Fabbricazione di Bossoli e Scatole Metalliche, G. Franchi and Co., Italy.*)
6100. Appliance for Tubes, W. E. Carmont, London.
6100. Valve, W. E. Carmont, London.

19th March, 1896.

6101. Mottie String, J. W. Cuffling and J. Unwin, Ridgeway.
6102. Saucepan Lid, E. A. Barnes, Pembroke Dock.
6103. Gas Engines, J. Enright, London.
6104. Making Decorations on Paper, A. Lipscombe, Surrey.
6105. Syphon Flushing Cisterns, F. C. Lynde, Manchester.
6106. Tool for Re-cutting Grooves, G. E. Cornioley.—(*G. Rabe, Germany.*)
6107. Door Knob with Spindle, H. Askew, Rotherham.
6108. Purifying Saccharine, F. Sykes.—(*R. Hirsch, Germany.*)
6109. Bowl Balls, W. Brocklebank, Nottingham.
6110. Match Box made from Mussel Shell, G. F. Blower, Ramsgate.
6111. Extinguishing for Burners, W. Redman, Wolverhampton.
6112. Driving Gear for Brake, J. T. Bustin, New Brunswick.
6113. Adapting Telephone Line Wires, A. G. Burrell, Sheffield.
6114. Wheels, F. Cook, Glasgow.
6115. Forceps, F. Wagner, Berlin.
6116. Rollers, E. Sykes, E. Heppenstall, and E. Sykes, Halifax.
6117. Bottle Screw Stopper, &c., L. Vallett, Liverpool.
6118. Metallic Bedstead Pillar Mounts, E. Lawson, Birmingham.
6119. Boot-blacking Machines, R. L. Tapscott, Liverpool.
6120. Patent Opener for Letters, A. H. Lowe, Glasgow.
6121. Producing Vapour for Inhalation, T. W. Rees, Cardiff.
6122. Sure and Safe, D. McPhun, Argyleshire.
6123. Ruling Machine, E. Graber and L. Hepworth, London.
6124. Ruling Machines, E. Graber and L. Hepworth, London.
6125. Flushing Water-closets, T. W. Twyford, Birmingham.
6126. Machines for Spinning Rope Yarns, J. McClure, Glasgow.
6127. Movable Seat for Polo Carts, H. McMullan, Glasgow.
6128. Ovens for Baking Porcelain, &c., W. Dall, Glasgow.
6129. Milking Apparatus, W. H. Lawrence and R. Kennedy, Glasgow.
6130. A Microscope, R. B. Brown, York.
6131. Fastening Arms to Flanged Rings, J. W. Lea and J. H. Perrins, Birmingham.
6132. Treatment of Impure Waters, H. B. Sharp, Manchester.
6133. Manufacture of Covered Whalebone, J. Hall, Manchester.
6134. Polishing Granite Balls, R. Lawrence, Glasgow.
6135. Furnaces of Steam Boilers, R. H. Williamson, Manchester.
6136. Extinguishing Lamps, G. Stork and T. H. Lee, London.
6137. Holding the Cords of Pictures, J. J. James, Birmingham.
6138. Attaching Postage Stamps, E. S. Fardell and C. E. Smith, London.
6139. Rims of Wheels for Cycles, &c., R. Corsham, London.
6140. Looms for Weaving, G. H. Sargent, R. H. Coupe, and B. Walker, Bradford.
6141. Fastening Means for Boots, J. C. Rhodes, London.
6142. Machines for Drilling, E. F. Moy and T. J. Digby, London.
6143. Billiard Tables, J. Turns and the Pneumatic Billiard Cushion Syndicate, London.
6144. Water Taps or Faucets, C. Flick, Barmen, Germany.
6145. Photographic Mountings, J. F. Hoyne and D. B. Athol, Dublin.
6146. Ornamental Edgings, C. Draeger and W. Gunn, Manchester.
6147. Treating Brewers' Grains, &c., F. B. Pike, London.
6148. Fittings for Electric Lighting, H. Lea, Birmingham.
6149. Releasing Tubes from the Mandrel, W. and A Pilkington, Birmingham.
6150. Oil Lamps for Lighting Purposes, R. Dorsett, London.
6151. Closing of Canisters, Boxes, &c., H. Mardon, London.
6152. Wickless Oil Lamps, J. F. Duke, London.
6153. Roller Bearings, W. H. Woodcock, London.
6154. Holders for Umbrellas, J. A. Gregory, Liverpool.
6155. Fastener for Boxes, &c., H. Fregberger, Manchester.
6156. Heel Tips for Boots and Shoes, V. A. P. Louis, London.
6157. Separation of Silicic Acid, &c., F. Brünjes, London.
6158. Lathes, R. G. Brooke, London.
6159. Shirts, W. Hayter, London.
6160. Eyelets, E. Kempshall, London.
6161. Water-tube Steam Boilers, A. F. Yarrow, London.
6162. Water-tube Steam Boilers, &c., A. F. Yarrow, London.
6163. Water-tube Steam Boilers, A. F. Yarrow, London.
6164. Separating Dust from Air, H. Simon, London.
6165. Flexible Tubing, &c., W. H. K. Bowley, London.
6166. Horse Collars, S. H. Brambley, London.
6167. Marine Boilers, N. Soliani, London.
6168. Saddles for Cycles, N. R. Roskell, London.
6169. Chimneys, M. T. Lander, London.
6170. Linotype Machines, The Linotype Company, C. L. Ireland, and F. J. Wich, London.
6171. Locking Devices for Nuts, &c., J. W. Cooper, London.
6172. Cooking of Food Materials, H. Higgins, London.
6173. Boots, B. Toon, J. W. Black, and A. Adcock, London.
6174. Fluid-pressure Motors, G. Sellers, London.
6175. Keyboard for Pianofortes, &c., T. Norton, London.
6176. Working Theatrical Scenery, R. Affleck, London.
6177. Self-moving Carriages, F. H. Wenham, London.

20th March, 1896.

6178. Keeping Bouquets Fresh, J. Hall, Dundee.
6179. Back-pressure Valve Cocks &c., T. Sabine, Derby.
6180. Tea-pots, C. H. Dent, Tamworth.
6181. Apparatus for Feeding Steam Boilers, J. Weir, Glasgow.
6182. Disinfecting Apparatus, P. S. Hyslop, Glasgow.
6183. Propellers, J. Paris, Glasgow.
6184. Boilers for Gas Cooking Stoves, L. Redmayne, Sheffield.
6185. Improved Shower and Spray Bath, C. Darrah, Manchester.
6186. Garment Cutting and Making, J. Walsh, London.
6187. Bedstead Pillar Mounts, J. W. Hoyland and R. W. Littleboy, Birmingham.
6188. Spectacles and Eye-glasses, T. J. Phipps, Herts.
6189. Re-bounding Twine Box, H. Auton, Crewe.
6190. Condenser, G. Love, Durham.
6191. Safety Tower Bolt, M. P. Galloway Leith.
6192. Hooks and Eyes, E. Mackenzie and C. Mackenzie, Dundee.
6193. Adjustable Cycle Seats, G. E. P. Gaskell, London.
6194. Musical Instrument for Singers, A. Walhorn, Glasgow.
6195. Squeegee, M. P. Galloway, Leith.
6196. Tube Spinning, &c., Machinery, W. Firth, Bradford.
6197. Electric Traction, T. E. Doyle and J. McKenny Dublin.
6198. Cycle Brake, A. A. J. Hall, Glasgow.
6199. Oil Lamps and Stoves, E. F. Hulse, Manchester.
6200. Receptacle or Box for Matches, H. Dawson, Keighley.
6201. Vehicle Wheels, F. Warwick and E. Warwick, Birmingham.
6202. Pneumatic Wheel, J. B. Small, P. Maclellan, and J. W. O. Walker, Glasgow.

6203. Fire Screen, W. Grosvenor-Bradley, Manchester.
6224. Fire Screen, W. Grosvenor-Bradley, Manchester.
6205. Brake Apparatus for Vehicles, L. R. Thomas, Wiltshire.
6206. Bicycles D. du Boulay, Salisbury.
6207. Apparatus for Cooling Air, C. D. Barker, London.
6208. Electric Switches, A. Ballance and E. H. Hewson, London.
6209. Chalk Glue, P. H. Riemer, London.
6210. Charging Furnaces, S. T. and C. H. Wellman, London.
6211. Steering Handle Bar for Cycles, B. Naumann, London.
6212. Gas Generators, P. C. Frewin, London.
6213. Pen-holders, M. Klemisch, London.
6214. Game, V. Maillard and F. Haus, London.
6215. Belts or Straps, J. H. Wolff and J. Schimmel, London.
6216. Treatment of Sodium, C. H. Parker and J. Pullman, London.
6217. Flushing Cisterns, J. Jones and H. E. Price, London.
6218. Steering Mechanism of Cycles, C. C. Fontaine, London.
6219. Golf Clubs, J. A. Davison, London.
6220. Lavender Bags, L. Uwins and E. N. Uwins, London.
6221. Cycle Clip or Holder, F. H. Bluemel, London.
6222. Weighing Tea, E. A. Schacht, London.
6223. Cycle Clip, H. Hodges, London.
6224. Drain Pipe, L. A. Wilson and W. A. Brunning, London.
6225. Compasses and Trammels, W. T. Davies, Swansea.
6226. Felt Hat Forming Machines, J. B. Macqueen and R. Robinson, Manchester.
6227. Recording Votes, E. T. Hughes.—(*G. J. Sweeney, United States.*)
6228. Preventing Collision between Trains, H. Rakow and J. Stocker, London.
6229. Collapsible Bracket Device, A. Bramhall, Liverpool.
6230. Securing Horseshoes, M. Schwertführer, London.
6231. Treating Metallic Bars, T. S. Kendrick, Birmingham.
6232. Imitation of Wood, F. L. Schauermann and J. S. Cowper, London.
6233. Indicating Statements of Account, G. Doré, London.
6234. Painting Letters upon Glass, J. H. Parish, London.
6235. Controlling Engines for Raising Loads, G. Donkin, London.
6236. Connecting Parts of Furniture, J. Cassagne, London.
6237. Dial for Clocks, J. C. Hart, London.
6238. Bicycle Handles, T. G. Russell, London.
6239. Combined Driving and Riding Coat, A. B. Giles, London.
6240. Apparatus for Starching Articles, R. Oliver, London.
6241. Diaphragm System for Lenses, A. W. Penrose and W. Gambie, London.
6242. Separating and Saving Gold, J. Mait, London.
6243. Corking Machines, J. W. Flower and R. J. Cousins, London.
6244. Edging for Ladies' Dresses, S. Lemberger, London.
6245. Taking Photographic Pictures, M. Freudenberg, London.
6246. Vacuum Tubes, A. W. Isenthal, London.
6247. Punching Holes in Letters to be Filed, F. Müller, London.
6248. Stiffening Material for Corsets, &c., H. W. Reynolds, London.
6249. Boots, W. Howard, London.
6250. Bottles, M. M. J. O. O'Conor and A. L. Gruggen, London.
6251. Apparatus for Corking Bottles, C. Malmendier, London.
6252. Pulleys and Bands, G. F. Gautier, London.
6253. Making and Baking Rusks, W. Kutschke, London.
6254. Cooling Coke, W. Parley, London.
6255. Steam Turbines, P. J. C. Carron, London.

21st March, 1896.

6256. Toy for Advertising Purposes, E. J. Hayball and A. H. Deakin, London.
6257. Tips of Billiard Cues, E. W. Lancaster, Birmingham.
6258. Syphon Water-waste Preventer, W. H. Webster, York.
6259. Smoke Consumer, R. H. and W. H. Shiers, W. Gillespie, and C. H. Bottoms, Oldham.
6260. Railway Signal Apparatus, R. Coats and J. Landells, North Shields.
6261. Music Stands, W. F. Chapman, Leeds.
6262. Handles for Cricket Bats, &c., G. E. Haworth, Accrington.
6263. Apparatus for Laying on Paint, A. W. Thatcher, Birmingham.
6264. Bottling Machines, J. W. Crichton, Glasgow.
6265. Hand Stamps, J. Gardner, Manchester.
6266. Wheels, A. J. Lehmann, J. Hillyard, and G. T. Haigh, Liverpool.
6267. Oil Cans, J. Frail, Glasgow.
6268. Auxiliary Fittings to Fire-arms, J. Wolffe, Glasgow.
6269. Wooden Casings, C. J. Wightman and A. Hudson, Bradford.
6270. Treatment of Earths, J. S. Pattinson and Fawcett, Preston, and Co., Liverpool.
6271. New Tool, J. Forsythe and W. O. Stanley, Dublin.
6272. Combined Air-lock and Bulkhead Door, W. S. C. Greene, London.
6273. Applying Adhesive Stamps, C. Brewster, London.
6274. Pneumatic Tires, A. Nicholson, Dublin.
6275. Preventing Unsymmetrical Coins Entering Slots, A. Pollard, Burnley.
6276. Locks, W. E. Copping, London.
6277. Exposure of Photographic Plates, E. Mosely, London.
6278. Self-sealing Ink Wells, A. Thomson, Manchester.
6279. "In and Out" Indicators, J. P. Milbourne, Manchester.
6280. Working the Points on Tramway Lines, J. P. Milbourne, Manchester.
6281. Brake, C. H. Richardson, Bristol.
6282. Securing Sackings to Bedsteads, F. Hoskins, Birmingham.
6283. Watch Protectors, W. Smith and T. W. Baker, Leicester.
6284. Securing the Ends of Cornice Poles, J. G. Hall, Birmingham.
6285. Device for Fastening Boots, C. J. Crapper, London.
6286. Burners for Lamps, I. Schwarz, Manchester.
6287. Cycles, W. B. Bromley, London.
6288. Sliding Pivoted Window Sashes, W. Johnson, Shetland.
6289. Chemical Manure Mixer, E. Paternotte, Brussels.
6290. Double Aluminium Sulphides, D. Péniakoff, London.
6291. Churn, G. C. Oeters, London.
6292. Bungs for Barrels, G. Busby, Birmingham.
6293. Die for Manufacture of Tiles, J. Sherwin, Manchester.
6294. Kinographic Apparatus, W. Hunt and J. Trotter, Lanark.
6295. Spacing Pieces for Type-setting, E. Wentscher, London.
6296. Cycle Bracket Holder, L. Fisher, Wolverhampton.
6297. Honeycomb Foundation Manufacture, J. H. Howard.—(*E. B. Weed, United States.*)
6298. Bicycles, F. L. Emanuel, London.
6299. Selvedge Motion for Looms, A. Walton, London.
6300. Locking Velocipedes, J. H. Hughes and G. Capewell, Birmingham.
6301. Spiral Track Pleasure Towers, T. W. Heath, London.
6302. Seam-rubbers for Boot-closing, T. Parris, London.
6303. Hoes, A. Foste-Melliar, London.
6304. Shirt Sleeves, W. F. Williams, London.
6305. Surface Trolleys for Electric Railways, W. S. Hull, London.
6306. Electric Motors, A. Greenwood, London.
6307. Knitting Machinery, S. Lowe, London.
6308. Locking Devices for Boxes, A. J. Boult.—(*J. E. Deconinck, France.*)
6309. Staple for Carriage-door Locks, H. Defries, London.
6310. Internally Stoppered Bottles, A. F. Spencer, London.
6311. Advertising, M. J. Allen, London.
6312. Lubricating Chain Gear of Cycles, T. Price, London.
6313. Buckles, I. Parkinson, Liverpool.
6314. Curtain Rings, I. Parkinson, Liverpool.
6315. Purses, I. Parkinson, Liverpool.
6316. Steam Boilers, G. Rollo and M. M. Rollo, Liverpool.
6317. Haulage Clips, L. Worthington and J. Soar, London.
6318. Treating Vegetable, &c., Fibre, J. F. Lester, London.
6319. Holder for Blind-cords, &c., G. R. Downer, London.
6320. Fastener for Collars of Uniforms, C. Schmidt, London.
6321. Cutting Leather, F. Squire and F. Squire, jun., London.
6322. Construction of Poles for Punts, &c., T. Myers, London.
6323. Tanning Skins without Acids, C. Marter and M. J. Myers, London.
6324. Engines Worked by Compressed Air, J. Molas, London.
6325. Supporting Objects in Varied Positions, C. Nube, London.
6326. Charging Pneumatic Tires, H. H. Johnson, London.
6327. Money-box, C. J. Berridge, London.
6328. Holder for Curling Tongs, A. Mosely, London.
6329. Applying Electricity, E. J. Preston and A. B. Gill, London.
6330. Scaffolds, P. Jensen.—(*Kaufmann and Heiland, Germany.*)
6331. Engines Operated by Steam, W. H. Scott, London.
6332. Combined Adjustable Calendar, J. B. Thomas, London.
6333. Pencils, S. W. Pedley, London.
6334. Cranks, L. P. Crace, London.
6335. Steam Generators, H. Matheson, London.
6336. Paper Making Machines, H. H. Lake.—(*C. Christophersen and O. Wahlberg, Norway.*)
6337. Ore Concentrators, F. J. Woods, London.
6338. Churns, T. Bradford, London.
6339. Saddle for Velocipedes, L. Périssé, London.

23rd March, 1896.

6340. Scythes and Reaping-hooks, F. Parkes, Birmingham.
6341. Ploughs, F. H. Keane, Waterford.
6342. Tilting Automatic Sand-box, J. F. Chapman, Stonehouse.
6343. Flexible Needle, A. A. Roberts, Waterloo, near Liverpool.
6344. Flax, &c., Spinning Machinery, T. Watson, Belfast.
6345. Nailless Horseshoe, J. Tobin, Cork.
6346. Tubular Lanterns, W. Redman, Wolverhampton.
6347. Cut Outline Maps, &c., B. Hoyland, Barley Royston.
6348. Corrugated Wire Netting, S. M. Wilmot, Bristol.
6349. Illuminating Apparatus, H. Hart, London.
6350. Valve-gear of Engines, M. Watson and J. G. Joicey, Newcastle-on-Tyne.
6351. Loading Coal into Ships, E. W. Crone and R. Wight, Newcastle-on-Tyne.
6352. Horticultural Seed Hand-drill, J. Elsley, Alcester.
6353. Construction of Kitchen Fenders, W. P. Eglin, Halifax.
6354. Steam Boiler Furnaces, T. York, Birmingham.
6355. Mouth-piece for Cigar Holder, W. P. Thompson.—(*H. Heisler, Austria.*)
6356. Pendulum Escapement, W. P. Thompson.—(*J. C. Bauer, Germany.*)
6357. Coal Tongs, J. A. Crane and C. E. Thomas, Birmingham.
6358. Trawl Gangways, A. Jeffs, Grimsby.
6359. Supporting Post for Bicycles, R. F. W. Beardsley, Glasgow.
6360. Brackets for Curtain Rods, J. Jones, Liverpool.
6361. Pneumatic Tire for Bicycles, W. W. Gibson, Kidderminster.
6362. Enema Apparatus, &c., W. T. Whitmore, London.
6363. Brake for Tramcars and Vehicles, J. Willis, Belfast.
6364. Distributing Tapes into Fabrics, H. Longbottom, Bradford.
6365. Rope Grip for Lifts, M. Robinson, Newcastle-on-Tyne.
6366. Rat Trap, J. B. Pohl, London.
6367. Lubricating Crank-pins of Engines, B. Robinson, Bolton.
6368. Display of Advertisements on Metal Plates, W. Walters and The Birmingham Advertising Tablet Company, London.
6369. Road Vehicles, B. G. King, London.
6370. Fish-trawling Apparatus, J. H. Maclure and W. A. Massey, London.
6371. System of Propelling Boats, M. Chenivesse, London.
6372. Unrolling and Measuring Cloths, H. James, London.
6373. Bath Thermometer, W. F. Hussey, sen., London.
6374. Electric Traction, D. Korda and A. G. New, London.
6375. Method of Opening Tins or Cases, J. W. Brooke, Lowestoft.
6376. Axles of Railway Carriages, H. Biermann, London.
6377. Producing Highly Overheated Steam, D. Adorján, London.
6378. Valve Motion and Engine, D. Adorján, London.
6379. Combing Machinery, W. Johns and R. Hancock, London.
6380. Fuel Economisers, E. Green, London.
6381. Penholders, W. C. Stevenson, London.
6382. Jacquard Machines, G. and F. Priestley, Bradford.
6383. Safety Folding Fire-guard, &c., R. Abrey, London.
6384. Pneumatic Tires, W. and I. Darby and J. H. Punchard, London.
6385. Draw Gear for Road Vehicles, H. Stanbridge, London.
6386. Time and Date Changing Stamp, D. G. Cavé, London.
6387. Portable Closed-in Stove, W. and I. Darby and J. H. Punchard, London.
6388. Driving Gear of Bicycles, A. J. Boult.—(*R. S. Dixon and J. J. Marshall, Australia.*)
6389. Manufacture of Celluloid, M. E. Asselot, London.
6390. Dyeing Materials, H. A. Brownsword and L. O. Lindley, London.
6391. Hose Pipes, H. W. Brüning, London.
6392. Combined Bicycle Rest and Pump, J. Emery, London.
6393. Natural and Artificial Ambers, F. Spiller, London.
6394. Machinery for Cycle Wheels, G. Skinner, London.
6395. Gearing, W. P. Thompson.—(*P. Langat, J. Jacque, and Société H. Dalifol et Cie., France.*)
6396. Blacking for Leather and the like, K. Thon, London.
6397. Conduits Applicable for Wires, J. J. Bate, Liverpool.
6398. Preparing Diagrams of Music, &c., G. Baty, Manchester.
6399. Driving and Controlling Animals, J. Welsh, Birmingham.
6400. Elastic Supports or Pads, &c., G. Uhlmann, London.
6401. Corset Stiffeners, E. Joseph, London.
6402. Foundations for Wigs, &c., E. de la Salle, London.
6403. Ink Guard or Finger Support, H. Lombard, London.
6404. Device for Stopping Horses, &c., B. Benny, London.
6405. Manure, N. F. B. De Mercey, London.
6406. Dress Fasteners, L. McCreary, London.
6407. Coating Articles with Zinc, W. S. Rawson, London.
6408. Oxygen Gas, A. Sweetser, London.
6409. Traces for Draught Harness, J. B. Chevillard, London.
6410. Albumen Tannin, W. L. Wise.—(*Knoll and Co., Germany.*)
6411. Regulating Bunsen Burners, &c., E. Savor, London.
6412. Woven Fabrics, H. H. Lake.—(*The Firm of D. Billwiller, Italy.*)
6413. Riding Habits, P. Nillson, London.
6414. Bags for Packing Food, &c., W. H. Feltham, London.
6415. Pneumatic Hat Lining, F. Hughes.—(*J. M. T. Mare, Australia.*)
6416. Sanitary Flushing Cistern, A. T. Handley, London.
6417. Driving Gear, H. J. Dowsing and F. Bremer, London.
6418. Tacking or Nailing Machines, F. Cutlan, London.
6419. Self-propelled Carriages, H. C. Capel and T. Clarkson, London.
6420. Detonating Fog Signals, &c., L. Waydelin, London.
6421. Golf Clubs, F. W. Brewster, London.
6422. Golf Clubs, F. W. Brewster, London.
6423. Switches, W. H. Dingle and J. M. Urquhart, London.
6424. Ventilating and Purifying Air, J. A. Hart, London.
6425. Pneumatic Tires for Cycles, C. F. A. H. Bagot, London.
6426. Lamp-carrying Bracket, J. Woldthausen, London.
6427. Transmitting Power, Keats Bros., Ld.—(*J. and S. Keats, France.*)
6428. Finishing Boots, Keats Bros., Ld.—(*J. and S. Keats, France.*)
6429. Ball Bearings, Keats Bros., Ld.—(*S. Keats, France.*)
6430. Inserting Rivets in Boot Soles, R. Poore, London.
6431. Explosive Compounds, A. V. Newton.—(*A. Nobel, France.*)
6432. Adjustable Fastening for Gloves, &c., R. H. Bishop and W. Down, London.
6433. Holding Window Sashes, E. R. Calthrop and J. C. Taite, London.
6434. Polishing Cloths, A. A. Attree and M. Robinson, London.
6435. Mats for Lamps, A. A. Attree and M. Robinson, London.
6436. Shelling Small Seeds, H. H. Lake.—(*G. Strafurini, Italy.*)
6437. Current Collectors, H. H. Lake.—(*Union Electricitates Gesellschaft, Germany.*)
6438. Bearings for Vehicles, P. F. Turner, C. McBride, and E. Klahn, London.

24th March, 1896.

6439. Handle Clip, G. K. Letts, Northampton.
6440. Cushioned Cotton Reel, E. Enock, London.
6441. Buffer Guides, W. Austin, London.
6442. Golf Club Head, W. Frier, Edinburgh.
6443. Metallic Bedstead Mounts, J. W. Hoyland and R. W. Littleboy, Birmingham.
6444. Pneumatic Tires, F. S. Cocks and W. H. Goodman, Peterborough.
6445. Runners for Umbrellas, &c., D. Bergmann, London.
6446. Alarm-bell for Cycles, &c., H. Brockas, Coventry.
6447. Brush, S. Draper, Dublin.
6448. Message or Letter Holder, R. H. Baker, Liverpool.
6449. Whetting Stone, J. I. Booker and R. Robson, Leeds.
6450. Match Box, K. M. Davies, Liverpool.
6451. Flanges for Jointing Tubes, R. Baird, Glasgow.
6452. Motors, H. Gee, Manchester.
6453. Resinous Solutions and Mixtures, H. Wendler, Manchester.
6454. Gas Burners, M. Clare, A. Niel, and Fletcher, Russell, and Co., Manchester.
6455. Vapour Lamps, H. B. Moran and J. B. de Lery, Manchester.
6456. Ruling Machines, D. E. Hipwell, London.
6457. Coffin Furniture, W. A. Bruff, Birmingham.
6458. Change-box Motions, G. Leek, H. S. and G. E. Walker, Lancashire.
6459. Ploughs, G. P. le Cappelain, Jersey.
6460. Taper-bend Pipe for Drains, J. W. Mearns, Sunderland.
6461. Fasteners for Windows, H. Redgate, Nottingham.
6462. Mandrels, H. and R. Speakman, London.
6463. Powder for Toilet Purposes, F. T. Gordon, Birkenhead.
6464. Cleansing Clothes, W. H. and H. Sugden, and S. Woodrup, Keighley.
6465. Sheet Metal Roofing, T. von Karlowski, Glasgow.
6466. Clips for Ball Programmes, L. Emanuel, Birmingham.
6467. Roller and Ball Bearings, R. Brenner, Crayford.
6468. Pneumatic Tires for Cycles, J. W. Smallman, Nuneaton.
6469. Wearing Apparel, C. Sunderland, Liverpool.
6470. Blotters, J. Temler, London.
6471. Pumps, J. Allan, C. B. Crowe, and T. A. Reed, Blyth.
6472. Securing Door Mats, J. J. James, Birmingham.
6473. Treatment of Refractory Ores, H. R. Angel, London.
6474. Dropping Bottles, A. B. Calder, London.
6475. Artificial Horizons, G. W. Heath, London.
6476. Advertising Machines, S. S. Bromhead.—(*S. Silberberg, United States.*)
6477. Electric Light Fittings, &c., G. O. Donovan, London.
6478. Cases for Manuscripts, &c., F. Friedrishs, London.
6479. Alarm Clocks, E. Benest, London.
6480. Rail Bond and Connection, E. A. Turner, London.
6481. Supplying Electricity, A. Mégros, London.
6482. Spanner, G. C. Downing.—(*F. Piron and P. Rouselle, France.*)
6483. Apparatus for Packing Tea, N. W. H. Sharpe, London.
6484. Writing Cases, Portfolios, &c., F. Wich, London.
6485. Motor, G. J. J. Legrand, London.
6486. Corsets, H. H. Lake.—(*N. F. T. Hunt, United States.*)
6487. Electric Motors, J. Devonshire.—(*E. D. Priest, United States.*)
6488. Riding Cycle Machines, M. Fabbrucci, London.
6489. Photographic Cameras, C. Beck, and W. Beck, jun., and J. T. Clarke, Harrow.
6490. Sewing Machines, L. E. Blackwell, London.
6491. Pocket Flasks, G. Nathan and R. Hayes, Birmingham.
6492. Pincers, J. A. Brown, London.
6493. Steam Boilers, S. Pitt.—(*La Compagnie Internationale des Procédés Adolphe Seigle, France.*)

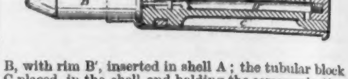
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

552,090. Miniature Ammunition, *H. Andrews, London, England.—Filed December 31st*, 1892.

Claim.—(1) A tubular piece, adapted to hold a cartridge composed of a shell A, provided with an internal tubular block C, carrying the communicating pin or striker D, and having a split ring G, surrounding said block C, at its front end, substantially as and for the purpose set forth. (2) A tubular piece adapted to hold a cartridge composed of the shell A, made of metal of the shape shown; the miniature cartridge B, with rim B′, inserted in shell A; the tubular block C placed in the shell and holding the communicating pin or striker D, the head F placed in cavity C^2 of the block C as described; and the split ring G, surrounding the block C at the front end as described, and all arranged as described and for the purpose set forth.

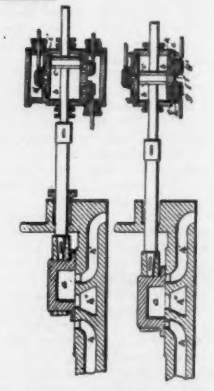
552,090



552,156. Valve Gear, *G. A. J. Telge, Oldenburg, Germany.—Filed February 21st*, 1895.

Claim.—In a valve motion for steam engines, the combination of the main slide *a*, of the main steam cylinder, the valve cylinder *b*, the valve piston *c* working in cylinder *b* and connected with slide *a* through a suitable rod, channels *i*, *i′* and *i″* on one side of cylinder *b*, slide valve *d* controlling said channels, the channels *e*, *e′*, *f*, *f′*, *k*, and *k′* on the other side of said cylinder *b*, slide valves *g*, *g′* controlling said channels, and suitable operating mechanism, substantially as and for the purpose set forth.

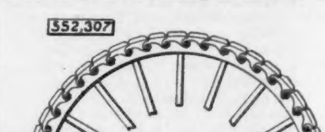
552,156



552,307. Elastic Tire for Wheels, *J. Tonks, Birmingham, England.—Filed June 20th*, 1895.

Claim.—(1) A sectional elastic tire for the wheels of common road vehicles formed of a series of metallic sections shaped so as to embrace the ordinary metallic tire and wooden fellies, and hook together at the sides of the same and each provided with one or more india-rubber blocks which together form the wheel tread and fit in corresponding perforations in the metallic sections and extend between the insides of the metallic sections and the periphery of the ordinary metal tire of the wheel, all substantially as described. (2) A sectional elastic tire comprising the metallic sections having the depending sides with hooks at the front ends thereof, and studs at the rear of said sides to receive the hooks of the adjacent sections, said sections having the opening a^4 in the upper part with inwardly turned flanges a' and the grooved rubber blocks held by said flanges, substantially as described.

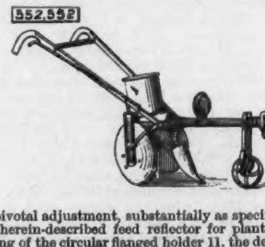
552,307



552,552. Sight-feed for Planters, *J. D. Schofield, Dallas, Tex.—Filed July 25th*, 1895.

Claim.—(1) The combination with a planter, of a feed reflector pivotally supported thereon in front of the feed mechanism for back and forth adjustment, and means for securing the reflector at any point of its pivotal adjustment, substantially as specified. (2) The herein-described feed reflector for planters, consisting of the circular flanged holder 11, the depending perforated beam embracing ears 13 cast in a single piece, the adjusting bolt 16, and the mirror 15, substantially as specified.

552,552



NOTES ON LIGHT RAILWAYS ABROAD: THEIR PERMANENT WAY AND ROLLING STOCK.

THE construction and working of light railways being now so much under consideration, a description will be of interest of the narrow-gauge lines which have been already established and worked many years in other countries. In the course of this description it will be shown how the difficulties of fixing the gauge and the transhipment of goods have, in accordance with the local circumstances, been practically overcome by the different arrangements adopted. The country most advanced in the development and beneficial working of narrow-gauge lines is at the present moment Belgium, where the most powerful and best organised society to this end has been established. It is financially assisted by all the districts through which the lines pass, by the Government, and by public subscription. It depends on and is controlled by the Board of Public Works, Railways, Posts and Telegraphs. This is the "Société Nationale des Chemins de Fer Vicinaux," and is the only authorised governmental concessionaire of the kingdom. The provinces or districts desiring lines to be established apply through their local authorities, to the Société Nationale, who after thoroughly examining the probable prospects of the line paying its way, or at least covering the cost of construction, working, and maintenance, applies to the Government for the concession. If authorised, the Government pays a subvention of from quarter to half of the capital, and guarantees an interest, while the rest is subscribed for by the corresponding provinces or districts and the public. The Government reserves, however, the right of either directing the Société Nationale to build the lines they will require, or to construct the lines themselves, paying compensation to the society, if the concession has been granted to them before. The Société Nationale des Chemins de Fer Vicinaux is at present concessionaire of 66 lines, comprising 1342 kiloms. (832 miles) with 84 new lines, inclusive of extensions extending to 1424 kiloms. (883 miles) in construction and working.

Gauge.—After long and careful investigations and long practical experience, the society adopted the metre (3ft. $3\frac{3}{8}$in.) as the standard gauge, and has now:—

53 lines, comprising 1056 kiloms. (655 miles) of 1 m. gauge.
8 " " 239 " 148 " " 1·067 "
5 " " 64·5 " 40 " " 1·435 "

The gauge of 1·067 m. (3ft. 6in.) was adopted to suit the Dutch lines they join, while for the other few lines of 1·435 (4ft. $8\frac{1}{2}$in.) gauge, the particular reason was that for those special cases it became important to avoid any transhipment of goods.

System of traction.—Out of 62 lines 60 lines, comprising about 1232 kiloms. (764 miles) are worked by steam, one of 5·1 kiloms. (about 3 miles) by horses, and one by electricity. Besides the above-mentioned 66 lines, there are six other steam tramways at work of a total length of 57·6 kiloms. (36 miles) which the Government had constructed and worked, for special reasons, by some private companies. Adding these lines, the number of light or narrow gauge lines worked in Belgium reaches the respectable figure of 72, comprising 1399 kiloms. (867 miles).

Working of the lines: The staff.—There are about 185 permanent officials for the whole service of all the lines. They are either paid by the day or month. The Société Nationale is anxiously considering the questions of fixing a scale of minimum wages, insurance against accidents, and old age pension.

Capital.—The working capital of all the lines is, in round figures, 57,024,000f. (£2,281,000).

Rolling-stock.—It consisted, up to the end of last year, of 258 locomotives, 716 carriages, 1780 vehicles, comprising the luggage vans, goods wagons, and trucks, representing a capitalised value of 12,196,856f. (£487,874).

Expenses.—The average cost for rolling stock and transport material per kilometre—or 0·62 of a mile—is 9813f. (£392·52) corresponding to about £633·09 per mile.

The average number of rolling stock in use is—

1 Locomotive for 4·912 kiloms. (or about 3·04 miles) of main line.
1 Passenger carriage for 1·734 kiloms. (or about 1·07 miles) of main line.
1 Luggage van for 8·878 kiloms. (or about 5·5 miles) of main line.
1 Goods wagon for 0·758 kilom. (or about 0·47 mile) of main line.

The 258 locomotives in service are subdivided as follows:—There are at work—

				Weight in full working order.
13	Locomotives for 1 m. gauge (3ft. $3\frac{3}{8}$in.) of			15 tons.
4	ditto	ditto	ditto	17 tons.
158	ditto	ditto	ditto	18 tons.
6	ditto	ditto	ditto	22 tons.
17	ditto	ditto	ditto	24 tons.
5	ditto	ditto	ditto	$27\frac{1}{2}$ tons.
3	ditto	ditto	ditto	30 tons.
6	Locomotives for 1·067 m. gauge (3ft. 6in.) of			11 tons.
1	ditto	ditto	ditto	17 tons.
31	ditto	ditto	ditto	18 tons.
9	Locomotives for 1·435 m. gauge (4ft. $8\frac{1}{2}$in.) of			28 tons.

The 716 vehicles in service are subdivided in the following manner:—20 carriages for horse traction, of which 10 are closed and 10 open; 116 carriages of first-class compartments; 387 carriages of second-class compartments; 12 carriages of second-class, and provided with De Rechter's suspension system; 98 mixed carriages, that is, of first and second-class compartments; 30 ditto, and provided with De Rechter's suspension system; 21 mixed carriages with luggage and goods compartments; 14 mixed carriages of first and second-class and goods compartment, and on bogies; 8 mixed carriages of first and second class, on bogies; 10 carriages of second class, on bogies.

The 1780 vehicles are subdivided as follows:—140 luggage vans; 76 closed goods wagons of 5 tons; 188 ditto of 10 tons; 128 wagons with raised frames of 5 tons; 1018 ditto of 10 tons; 70 flat wagons of 5 tons; 151 ditto of 10 tons; 2 trucks to carry normal gauge line material; 1 truck of 20 tons for the transport of stones; besides three cranes and three cisterns.

Permanent way.—The narrow-gauge lines can be divided in three types: (1) Lines laid on the road sides; (2) lines laid across country roads, having, therefore, independent platform; (3) paved lines across towns. (1) Lines on road sides: The Société Nationale has adopted the Vignoles steel rail, weighing 21·5 kilos. (47·30 lb.) per lineal metre (3ft. $3\frac{3}{8}$in.), corresponding to about 43·25 lb. per yard. The sleepers are of oak, are creosoted, and of the following dimensions:—1·80 m. (5ft. $10\frac{7}{8}$in.) long, and 20 cm. ($7\frac{7}{8}$in.) wide, and 10 cm. ($3\frac{15}{16}$in.) deep, or 24 cm. ($9\frac{7}{16}$in.) wide, and 12 cm. ($4\frac{23}{32}$in.) deep, according to their being of rectangular or half-round shape. The rails are 9 m. (29ft. $6\frac{5}{16}$in.) long, and are supported on a straight line by ten sleepers, placed as represented in Fig. 1. Each sleeper is provided with an iron bearing or sole-plate to support the rail—as shown in Figs. 1 to 4—weighing 1 kilo. (2·2 lb.) each. Those sole or bearing plates were at the beginning only used at the rail joints; experience, however, had shown that it was preferable to use them on all sleepers. In curves, one sleeper more is used per rail-length. On the straight line, and in curves of more than 100 m. (328ft. 1in.) radius, the rail joints are unsupported. The short rail used on the inside of curves of 100 m. and more is of such a length that the number of 9 m. (29ft. $6\frac{5}{16}$ in.) rails used is exactly the same as the number of 9 m. rails used for the outside of the curve. For curves of smaller radius ordinary rails are used inside, the beginning and the end of the curve being filled up with odd pieces of rails, called stopping, filling up, or packing-piece rails; great care is taken, however, to break joint. The rails are connected by means of strong fish-plates shaped like angle irons; each pair, exclusive of bolts, weighing 10 kilos. (22 lb.), as represented in Fig. 2 to 4. The smallest radius adopted by the Société Nationale is 30 m. (98ft. $5\frac{1}{16}$in.), which is only used in very exceptional cases, when, through local conditions, it cannot be prevented. Circumstances compelling the Société Nationale to adopt such small curves occur mostly in passing through towns or agglomerations of industrial establishments. In the country or on open roads, where the lines are laid on independent platforms, the radius of the curves is never less than 75 m. (246ft. $0\frac{3}{4}$in.). On account of the great number of curves of small radius the Société Nationale has been particularly engaged with the study of laying out curves, and has issued a special circular on the subject, giving the necessary formulæ, designs, and methods by which to proceed. In general, the instruction contained in the circular is, that the elevation of the outer rail is to be obtained according to circumstances, either by raising the outer rail or by lowering the inner rail, or by following a mixed combination of raising the outer rail half of the elevation required and lowering the inner rail the other half, so that the centre line of the permanent way conserves exactly the necessary longitudinal elevation of the line. This last method is recommended as the best. The whole development of a curve of the same radius must have the same rise throughout. This elevation must be gained without any sharp or abrupt transition of gradients or inclines, and must be effected by gradual levelling. To obtain the rise gradually it is necessary to insert an adjusting curve between the straight line and the curve of the permanent way, which starts and finishes the rise, and of which the radius of curvature in each point corresponds to the elevation at this point. This adjusting curve is a parabolic curve, half of which is distributed on each side of the tangential point. The amount of rise to be given in the curves depends on the maximum speed of the trains. This is fixed at 30 kiloms. (18·6 miles) per hour in the country, and 10 kiloms. (6·2 miles) per hour in town, and can only be altered by special authorisation. In the country the curves will generally have a radius of at least 100 m. (328ft. 1in.) If for special reasons the radius of these curves is less than 100 m., a special signal post, painted a green or blue colour, is placed on the right-hand side of the line at 30 m. (98ft. 5in.) in advance of the starting point of the curve, to indicate to the driver that the speed when crossing the curve has to be reduced to 20 kiloms. (12·40 miles) per hour. Curves of less than 75 m. (246ft.) radius are not allowed for lines of a normal gauge of 1·435 m. (4ft. $8\frac{1}{2}$in.). For lines of 1·067 m. (3ft. 6in.) gauge, or of 1 m. (3ft. $3\frac{3}{8}$in.) gauge, curves of less than 50 m. (164ft. $0\frac{1}{4}$in.) radius are not allowed, except in towns and in special cases, as at the approach of a station or of a swing bridge, or at dangerous points, which compel either the slackening of speed or the stopping of the train. In towns or centres of industrial establishments, factories, &c., the smallest radius of curves for permanent way of reduced sections is not to be less than 30 m. (98ft. 5in.).

To determine the elevation of the outer rail, in the curves the Société Nationale has adopted the formulæ

$$S = \frac{l\,V^2}{g\,R}, \text{ in which}$$

l = gauge; V = maximum train speed per second.
g = force of gravity per second = 9·8088 m. (about 32ft. $2\frac{1}{8}$in.)
R = radius of curve.

The parabolic curve is the curve adopted as the line forming the union between the straight and the bend of the outer rail. The formulæ used for setting out this parabolic curve are as follows:—The length of the parabolic curve $p = \frac{P}{R}$, where

P = varying parameter,
R = radius of circle,

from which follows, that the positions of the tangential point T_0 of the straight line with the parabola

$$T = \tfrac{1}{2} P.$$

The tangential points T are exposed to a lateral displacement $T\,T^1$, given by the formulæ

$$T\,T^1 = \frac{P^2}{24\,R}$$

whereby the calculation proves that the centre of $T\,T^1$ is a third point of the parabola, while other points of the parabolic curve are obtained by the formulæ

$$y = \frac{1}{6\,P}\,x^3, \text{ whereby}$$

x = abscissa, reckoned from the new tangential point;
y = ordinate; while the radius of curvature p^1 of each point of the parabola is given by the formulæ

$$p^1 = \frac{P}{x}.$$

However, to facilitate the operations of setting out, standard tables are given to that effect, indicating the parabolic unions for all the radii generally in use.

In determining the elevation of the outer rail by means of the above formulæ, $S = \frac{l\,v^2}{g\,R}$, it is necessary, by adopting a value for v, to take into consideration the slow speed which is fixed for sharp curves of small radius, as otherwise the rise of the outer rail would be of such an exaggerated height, which no public authority would allow, especially in traversing towns or manufacturing centres. The Société Nationale has further decided not to allow any increase of gauge or widening of the permanent way in curves which are *not* below 50 m. (164ft. $\frac{1}{4}$in.) radius.

For the type of locomotives used on the society's lines the following clearance or excess in gauge is only allowed:—

In curves of	30 m. (98ft. 5in.) radius ...	0·01 cm. ($\frac{3}{8}$in.)
Ditto	35 m. (114f. 10in.) radius ...	0·007 mm. ($\frac{1}{4}$in.)
Ditto	40 m. (131ft. $2\frac{13}{16}$in.) radius	0·005 mm. ($\frac{3}{16}$in.)
Ditto	45m. (147ft. $7\frac{5}{8}$in.) radius ...	0·003 mm. ($\frac{1}{8}$in.)

The cross section of the permanent way varies according to the width of the roadside at disposal, as shown in Figs. 5 and 6. The line is bordered, dividing it off the road by a range of raised kerbstones, each of which is about 40 to 50 cm. ($15\frac{3}{4}$in. to 20in.) long, 30 to 40 cm. ($11\frac{3}{4}$in. to 15in.) high, and 13 cm. ($5\frac{1}{8}$in.) thick. This border permits the raised line to be kept dry and in a good state of preservation, preventing carts or other vehicles running it, to damage the permanent way, and to come in contact with the trains. As far as practically possible, these border stones are set against the road pavement, so that they touch each other, as seen in Figs. 5 and 6; but this method has sometimes to be abandoned, as either the roads do not go exactly parallel to the axis of the line or the roadside becomes too wide to be completely occupied by the platform or paved part of the line. In the case where the contact between the two borders cannot be maintained, some inconvenience will be experienced through the cart-wheels getting in the free and soft space left between the two borders, namely, the kerbstones of the line and the paving stones of the road. If the border stones do not run rigorously parallel the soft space left between them is then generally not very wide, and it can be filled up with small stones, gravel, &c. If, however, the cross section of the line is limited to a certain size, and a certain zone or part of the roadside has to be kept free, say, for example, of 50 cm. ($19\frac{3}{4}$in.) width, then the above-mentioned defect can only be remedied by paving the full width of the free space left between the two borders. The paving of such a width as given above would cause an additional expense of about 3000f. per kilometre (or about £193 10s. per mile).

To prevent the raised border or kerbstones from causing the water to collect on the road, a free space of 10 cm. (about 4in.) is left between two border stones wherever required, corresponding to a similar open channel dug out across the line, thus allowing all the water to flow freely into the road channel. Different other systems, but all very expensive, were brought forward and highly recommended as efficient means of preventing the kerbstone being the cause of the paving which is inclined towards the line not drying. None of these methods have given more effective results than the system used by the Société Nationale. It is simple, practical, and efficient, and requires only that the drains of the line shall be properly maintained and cleaned. This system of open transverse drains has been criticised. It is reproached with not giving the same facility to pedestrians to walk along the roadside of the line. The objection is not altogether unfounded, but considering the result obtained by this system, it is recommended. Besides, it is better, and in the interest of public safety, to keep pedestrians off the roadside occupied by a railway line. The use of raised borders or kerbstones influences sensibly the cost price of the narrow gauge lines laid along road sides; its cost varies from 1500f. to 3500f. (from £60 to £140) per kilometre, equivalent to £96·77 to £225·8 per mile, according to the distance of the quarries from the place where the stones are to be used, and the quality of the stones. The high value adopted as bending moment of the rails has permitted to modify the distance formerly adopted, between the sleepers of the $21\frac{1}{2}$ kilos. (47·3 lb.) rail. They are eight for a bay of 9 m. (29ft. $6\frac{5}{16}$in.). The method of laying the rails is shown in Figs. 1 and 7. The great depth of the 30 kilos. (66 lb.) rail requires the permanent way to be connected by metal cross stays or ties, represented in Figs. 7 to 10. The only modification in the cross section of the permanent way with 30 kilos. rail consists in laying somewhat more ballast on the line, on account of the great difference in height of the two types of rails. By joining the permanent way of $21\frac{1}{2}$ kilos. rail with one of 30 kilos. rail, the joint is made by means of a special fish-plate composed of one-half of each type welded together, called a compound fish-plate, fixed to each side of the rail, as shown in Figs. 11 to 13. The use of the $21\frac{1}{2}$ kilos. rail in combination with the 30 kilos. rail is caused by the former lighter rail being used on the country road, while the latter heavier rail is used in town, where pavement occurs. The consequence is, where both rails meet a joint had to be provided, which led to the above combination of a compound fish-plate. Figs. 20 and 21 also show how the use of both kinds of rails occurs. For lines established in centres of metallurgical industries, the Société Nationale have brought

"THE ENGINEER"

SWAIN ENG.

out and use very largely metallic sleepers of the Z form, as represented in Figs. 14 to 21. These sleepers have proved after long experience to be very good, and it is only their comparatively high price, in comparison to the present price of wooden sleepers, which prevents their general adoption. Some experiments, but not of a very extensive character, were also made with other systems of metallic sleepers, and of other special arrangements as to fixing the rail to the sleeper with no better, but rather inferior results. Figs. 14 to 16 represent the type A of the metallic Z sleepers—shown in Fig. 20—which is used up-country along road sides where there is no pavement, while Figs. 17 to 19 and Fig. 21 represent the type of metallic Z sleepers for paved roads. Fig. 16 and Fig. 19 show also in plan for both types the arrangement of the split pin, or rather split key, for fixing the rail. As will be seen from plan—Fig. 16—the closed key is driven in first and opened out afterwards, to grip the rail and have firm hold of it.

Ballast.—Some of the narrow-gauge or vicinal lines are ballasted with gravel or small broken stones, but these are exceptions, as the greater part of them, on economical grounds, are ballasted with cinders from large factories. There is under the sleeper at least a thickness of 20 cm. (7⅞in.) of ballast, which for permanent way laid along the roadside is raised flush to the top level of the rail, while for lines laid on independent platforms it is raised to the top level of the rail, along the centre line of the railway only.

(2) *Permanent way on independent tracks.*—The permanent way is laid on independent tracks in the following cases:—For lines in hilly countries leading to a main line of railways, or when the roads, which the narrow-gauge line has to follow, are—as seen in plan—of so many sharp curves and pronounced bends that they could not be properly adapted for a small railway line, or if they present steeper gradients than the limit allows. The independent formation becomes also necessary when the roads are too small. In this case, however, a wider area or zone of the roadway is taken for the establishment of the line. Gradients: The limit of steepness admitted by the Société Nationale is 3 cm. per metre—or about 1 in 33. This very steep gradient extends on some lines without interruption over several kilometres. Under exceptional circumstances still steeper gradients, but for very short distances only, were admitted reaching 6 cm. per metre—or about 1 in 17; but these special cases only occur in crossing towns or industrial centres. In Figs. 22 to 24 are represented the types of transverse sections followed for lines established on independent formation. There is no special arrangement which would distinguish them from the formation of ordinary railway lines, except that they are of smaller size. Fig. 22, however, shows the line established on embankment; while Fig. 23 shows the type of cross section of the line on cutting. The reduction in size does, of course, not apply to the formation of the slopes or to the cuttings or embankments.

(3) *Paved lines.*—The line is principally paved in traversing towns or industrial centres; while along the line pavements are laid at level crossings, communal passages leading to main roads and passages of private properties, or along industrial establishments situated in front of the road. As to the paving of any passages leading to private property, the Société Nationale was guided by the principle that a narrow gauge railway, making use of the roadside of a public highway, should offer them the same facilities of access to the public road as they had before the establishment of the railway. But, on the other hand, the Société Nationale considers that it is not obliged to put down pavements at their expense across the line or along industrial establishments, when such necessities arise, after the line has been established. In such cases the necessary work to gain access to the road should be carried out at the expense of the proprietor interested to get the passage, and only after he has received the necessary permission from the proper authorities to establish such level crossing. The raised border or kerbstone is broken off at all paved level crossings, but so that it is on both sides slanting down to the level of the passage. More often when the line is paved there is no kerbstone used. The repairs and maintenance of the pavement of the permanent way is a very serious item in the cost of the line. The principal cause of these nearly permanent repairs is the use of such big paving stones as those used by all public authorities in Belgium. The sample mostly used measures 14 to 16 cm. (5½in. to 6¼in.) at the head and at least 14 cm. (5½in.) at the bottom. It will easily be seen that it is impossible to raise the rail so much above the sleeper as to prevent the seat of the paving stone from receiving the effects of the vibrations produced by the passing train. (See Figs. 25, 26, 29, and 30.) These vibrations produce, especially at the beginning of the working of the line, the loosening of the paving stones laid above the sleepers, especially if there is no great and heavy traffic passing over the road. To minimise this injurious effect it is well to select shorter paving stones, or even if such cannot be obtained, to shorten the longer ones. For permanent way laid in pavement the 21·5 kilos. (47·3 lb.) rail is used, seated on cast iron shoes, which are fixed to the sleeper, as represented in Figs. 25 to 28.

Fig. 27

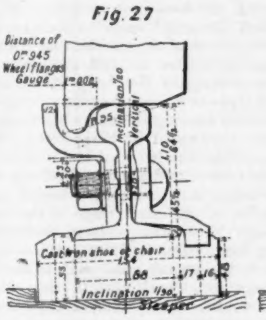

Fig. 28.

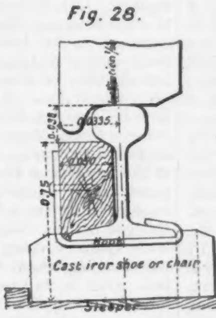

Fig. 29.

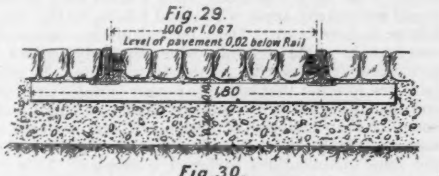

Fig. 30.

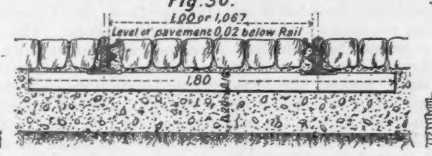

Fig. 31.

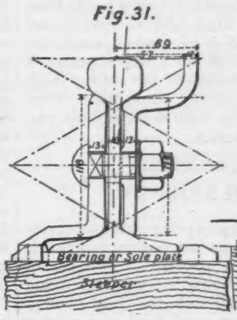

Fig. 32.

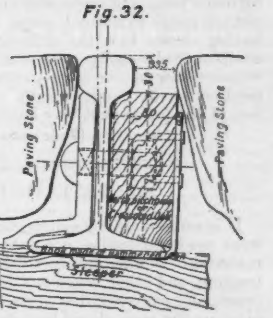

More generally, and especially in traversing towns or manufacturing or other industrial centres, the 30 kilos. (66 lb.) rail is used, which is directly placed on the sleeper by means of the usual intermediate sole or bearing plate, as shown in Figs. 30 and 31. To prevent the head of the rail coming in contact with the paving stones where the ordinary traffic runs, and to form a groove for the reception of the wheel flanges of the railway vehicles, two methods have been adopted. The one consists in placing against the rail a wooden distance piece or wooden curb, which is firmly held against the rail by means of an iron plate, one end of which is bent over the foot or bottom member of the rail, thus forming a hook, while its other end is screwed on to the wooden curb—as shown in Figs. 25, 28, 29, and 32. The wooden curb is thus fastened to the rail without drilling the latter. The other method consists in riveting or bolting to the rail a counter or guard rail, bent into angle iron shape, of which one end is fixed to the web of the rail, while the other end leaning against the pavement is bent into a curved shape, forming the groove to receive the flange of the wheel—as shown in Figs. 26, 27, 30, and 31. This shape is called the bayonet-rail, The part fixed to the rail is so arranged to be able to serve as fish-plate also; whereby, however, care is taken that its projection beyond the rail is equal to half the size of an ordinary fish-plate, and to use it at the other end only of the same length of a half fish-plate. In curves of less than 50 m. (164ft. ½in.) radius for the outside rail the guard or bayonet-rail is replaced by using the wood key for the formation of the groove, in which case, however, a stronger wood key is used, as on the ordinary line. This precaution is taken to prevent the wheel-flange getting wedged in the groove.

For the inner rail the grooved bayonet or counter rail is used throughout, serving as a guard rail at the same time. As the groove is, however, only 35 mm. (1⅜in.) wide, for curves of minimum radius, the bayonet rail is substituted, and the groove formed by means of an ordinary rail, which is bolted to the main rail of the line; while, on the other hand, cast iron distance pieces are inserted between them, thus maintaining the width of the groove. The paving between the rails is made of sets transversal to the direction of the line, and the paving stones in contact with the rails are alternately headers and ordinary paving stones, so as to form cross-joints without using half paving stones. On the outer side of the line the paving stones in contact with the rails are also alternately headers and ordinary paving stones. As will be seen hereafter when dealing with the cost price of the different kind of permanent way, the cost price of paved lines provided with guard rails forming a metallic groove is far higher than the one formed with wooden curbs; the former, however, looks better, stands better, gives a better pavement, and should preferably be used, especially in important towns and industrial centres. Metallic grooves naturally last longer, while those formed of wooden curbs, lasting only a very limited time, would oftener cause the lifting of the rails for repairs and maintenance, and thus increase the cost.

Fig. 24.

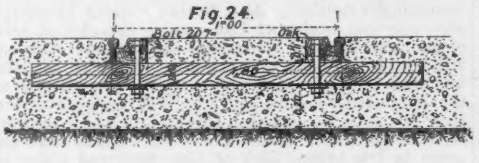

Fig. 25.

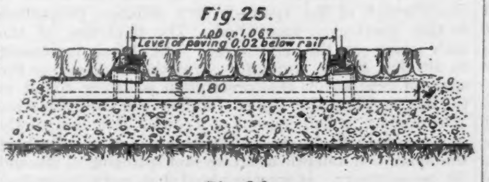

Fig. 26.

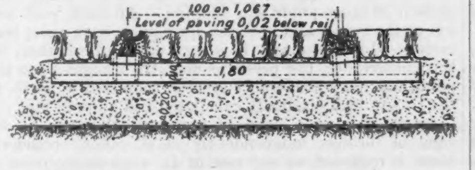

The cost price of the different kinds of permanent ways laid since 1888 summarises as follows:—

(*a*) Line laid on independent formation with 21½ kilos. (47·3 lb.) rail, 12,286f. per kilometre, or about £792 13s. per mile, as represented in Figs. 22 and 23.

(*b*) Line laid on road side, with same rail and raised border or kerbstone, 15,136f. per kilometre, or about £976 10s. per mile, as represented in Figs. 5 and 6.

(*c*) Line laid with old pavement, same rail of 21½ kilos., with groove formed by wood key, 17,173f. per kilometre, or about £1108 per mile.

(*d*) Line laid with old pavement and with 30 kilos. (66 lb.) rail, with groove formed by wood key, 18,478f. per kilometre, or about £1192 per mile.

(*e*) Line laid with old pavement and with 21½ kilos. rail, with groove formed of bent guard rail, 21,643f. per kilometre, or about £1396 6s. per mile.

(*f*) Line laid with old pavement, with 30 kilos. rail, with groove formed of bent guard rail, 23,124f. per kilometre, or about £1492 per mile.

(*g*) Line laid with new paving, with 21½ kilos. rail, with groove formed by wooden key, as represented in Fig. 25, 29,173f. per kilometre, or about £1882 per mile.

(*h*) Line laid with new paving, with 30 kilos. rail, with groove formed of wooden key, as represented in Fig. 29, 30,478f. per kilometre, or about £1966 per mile.

(*i*) Line laid with new paving, with 21½ kilos. rail, with groove formed of bent guard rail, as represented in Fig. 26, 33,643f. per kilometre, or about £2170 per mile.

(*j*) Line laid with new paving, with 30 kilos. rail, with groove formed of bent guard rail, as represented in Fig. 30, 35,124f. per kilometre, or about £2266 per mile.

Some apprehension has been felt in this country, in reference to the use of the narrow gauge permanent way, on account of the junction with the normal gauge of the main lines and the transhipment of goods, especially so in case of large farming districts, where farmers could on their farms only profitably use portable railways, with the corresponding rolling stock. This, again, would require some arrangement at the junction of the portable railway with the narrow gauge line for the transhipment and transport of market produce. This difficulty would, however, not occur in traversing manufacturing or other industrial centres. Other countries besides Belgium have dealt with this point and solved it in the best practical way, as the local conditions permitted. In France, the late M. Banderali, engineer-in-chief of the traction material of the Northern of France Railway, with whom the writer had some intercourse concerning steam tram service, and in connection with M. Sartiaux, also engineer of the Great Northern of France, have thoroughly considered the subject, and practically experimented with reference to some narrow gauge feeders of their main lines. These engineers considered the transhipment of goods for the time as the most practical and cheapest method. They reserved for this purpose special lines for loading and unloading in the goods-station yard. All the loaded wagons of the normal gauge line which were to be emptied into those of the narrow gauge were placed on a special line reserved for them, and reciprocally so the wagons of the narrow gauge line. These lines were specially reserved for the transhipment service alone, and were provided with all the necessary implements and material which the transhipment required, according to the nature of the goods. With proper disposition and a well organised service the cost of transhipment, according to the nature of the goods, varied from 2d. to 3d. per ton, and in exceptional cases only reached about 4d. For light goods requiring careful handling the narrow gauge line was raised so that the platforms of both goods wagons were level, and thus the goods were easily carried or shifted from one platform of the goods wagon to the other.

For goods of great bulk, as timber, stones, &c., movable cranes across the normal gauge were used for their transhipment either way. For lighter goods and of smaller size the unloading is effected by having the narrow gauge line on a lower level than the normal gauge, and unloading the heavier wagons of the normal line into those of the narrow gauge by means of iron plates laid from the floor of the high level normal gauge wagons down on the floor of the low level narrow gauge wagons, and over which the goods are made to slide. In the reverse case of loading from the low level narrow gauge into the high level normal gauge wagon, the narrow gauge line leads by means of a gradient to the level of the normal gauge, so that the floors of both wagons are on the same level. The loading is done from end to end of wagon, whereby corresponding sidings are so arranged that the loaded wagons of the normal gauge and the empty wagons of the narrow gauge are respectively shunted in the corresponding sidings, until the transhipment is done. The empties are sent back as empty train on the narrow gauge line, while the loaded goods wagons of the normal gauge are sent as loaded train to destination. It is only a matter of careful selection of sidings placed on different levels according to requirements, to effect the transhipment. These are principally the methods used in France. Some different methods besides these are used in Germany. The transhipment is not only effected by the unloading of the goods, but also by lifting the fully-loaded body of the goods wagon off the axle and wheel frame, by means of overhead travelling cranes. These are erected in the goods yard over the lines, spanning both lines at the same time. The traveller crosses from one line to the other, lifting and lowering the full-loaded body on to the wheel frame of one line to the other. This method is considered the most practical for breakable goods.

Another method is the following:—The narrow gauge line is laid between and in the centre of the normal gauge for such length as the loading operations require; and about 1ft. higher than the level of the normal gauge. A short-wheeled truck or cradle of the normal gauge is run into position under each of the axles of the narrow gauge wagon; both are then moved forward together to a short incline of, say, 1 : 10, where the rails of the normal gauge drop somewhere about 1in. or 2in.; this causes the axles of the narrow gauge wagon to get seated on the normal gauge cradles to which they are then firmly fixed. The wheel base of the cradles is about 3ft. The cradles carry a cross-beam, which is pivoted and bent downwards to get hold of the wheel flanges of the narrow gauge wagon, which supports them and prevents any damage to the wheels. A similar arrangement is made by reversing the system, to carry normal gauge goods wagons on narrow gauge lines. For large agricultural districts especially a somewhat similar arrangement is introduced by Oernstein and Koppel, contractors, of Berlin, by transporting farm carts used on ordinary roads, loaded or unloaded, on the portable railways used on farms, doing at one and the same time, as stated, the work of eight farm carts. They also use cradles, which are, however, provided with blocks, in which the carts get seated—as shown in Figs. 33 to 35. The cradles are made strong enough to run also on corresponding narrow gauge lines, from where the loaded carts could also be directly transhipped to wheeled frames of the normal gauge. It would thus be a continuous uninterrupted transport of the wagons up to destination without any previous unloading of goods, which would thus be preserved from any damage, and the whole transport would be effected at very moderate cost.

Having herewith recorded the different methods used in those countries where light railways are fully developed for many years and successfully used to forward goods from narrow gauge to normal gauge lines, and *vice versâ*, and having shown how the difficulties of transhipment are comparatively easily overcome at no great expense, it remains now to give some particulars of the rolling stock used on narrow gauge or light railway lines, the particulars of the permanent way having been described above.

(*To be continued.*)

CONCRETE ARCH BRIDGES.

It is some years since energetic and persevering attempts were made to utilise concrete as an ordinary building material. Numerous methods, processes, systems of framing, and other ingenious devices, were patented and practically experimented upon, all with the view of supplanting the ancient and time-honoured brick-and-mortar mode of construction. These laudable endeavours were, it is true, made more in the interest of the architect and builder than of the engineer, for the promoters of the new *régime* directed their attention chiefly to the employment of concrete as a suitable material for building ordinary dwelling-houses, warehouses, and similar structures. They left the great part, and for which it is pre-eminently suited, to be developed by the skill and care of the engineer, to whom it may be said to be now, especially in the matter of foundations, his sheet anchor. Although some habitable dwellings were erected of concrete, it is only necessary to give a glance at any building operations of the present day to demonstrate that, as a rule, the attempts to which we have referred were a failure. It is not far to seek for the causes of their want of success. Some are of a theoretical, others of a practical, character. In the first place, it was a troublesome and comparatively expensive job to put a good surface both inside and outside on the walls themselves. The frames, whether of timber or iron—for both descriptions of material were used—left deep scores, small furrows, and rough excrescences of all kinds, which demanded a liberal use of cement, trowel, and labour to eradicate. But the fundamental error in these attempts was in endeavouring to employ the material in positions and under conditions for which it was not adapted. Concrete, however perfect its mixing, consistency, and the incorporation of its ingredients may be, does not possess the bond of brickwork. Hence it is not to be wondered at, that the attempt to assimilate, as nearly as might be, the thickness of lofty walls of houses built of concrete to those of brickwork, should eventuate a failure. Concrete planks do not constitute an advantageous form in which to use that material either vertically or horizontally.

The value of concrete, in fact its very *raison d'être*, consists in its mass, in its weight. It is thus an excellent material for the construction of large and heavy massive works of all descriptions, such as retaining walls, docks, harbours, and breakwaters, where polish or beauty of surface is not an indispensable requirement. As an example of its unrivalled utility on a scale of magnitude, witness the mammoth blocks, over three hundred and fifty tons in weight, forming the north wall of the harbour of Dublin. It must be admitted that large blocks have been displaced by the action of storms, as at Madras, but it was simply because they were not large and heavy enough. Instances are not wanting, although they are by no means frequent, in which concrete has become cracked, fissured and disintegrated even when placed under the most favourable conditions, that is when deposited *en bloc*. A notable example was afforded shortly after the completion of the works of the Alexandra graving dock, Belfast, about six years ago. An investigation of the cause of the failure partially exonerated the material itself from blame. The concrete could not, or at any rate did not stand the continual flux and reflux of salt water heavily charged with magnesia. It was alleged that the magnesia, by a very ordinary chemical reaction, abstracted the lime out of the Portland cement, and so brought about the misfortune. At the same time there are an abundance of dock walls which have stood uninjured this action for years.

A high resistance to stresses of a compressive character, a cheap and expeditious process of manufacture, combined with an opportunity of using it under the most favourable circumstances, seems to indicate concrete as exceedingly well adapted to the construction of arches. It has been so utilised for the smaller specimens of arches, such as culverts, sewers and pipes, for many years, but it is only recently that it has been so applied to works of that class having any pretensions to magnitude. The delay may have been occasioned by the absence of experimental or empirical data respecting the absolute strength of the material when exposed to the action of a strong thrust. This, however, was not altogether owing to the entire absence of all such data, but to the fact that the experiments had been conducted on such a very limited scale as to furnish but very imperfect information respecting what the results might be when it became a question of building an arch of large span. Many of the early experiments were conducted with concrete arched ribs of a span of only 3ft., and a depth and width at the crown of 2in. respectively, thus giving a gross sectional area of four square inches, which was slightly increased towards the springings. Subsequently the span was increased to 10ft., but this dimension would be but a poor specimen upon which to base data for the strength of a similar structure over 100ft. in span. This was the fault of nearly all the earlier experimentalists, although they can hardly be blamed for it, considering the very rude and inefficient apparatus and machinery they had at their disposal, compared with the splendid and highly-finished instruments now in common use. The fault to which we allude was not so much the limited scale upon which the experiments were conducted, as the erroneous conclusions deduced from them. It was a serious error to suppose that a constant derived from an experiment, however carefully conducted, upon a small arch or beam, would necessarily apply with equal fidelity to the case of a large arch or beam. Data for calculation obtained in this manner would certainly, when similarly applied, not give correct results with respect to concrete. It should be borne in mind that concrete is very variable in quality; and that though it is not difficult to make a small arch or beam of that material of fairly good and uniform consistency, yet there is considerable difficulty in ensuring the same qualifications in larger examples. As a rule, constants deduced from experiments on small specimens are too high for those of greater dimensions. The early experiments made upon pine and other woods fully confirm this statement. Again, in the experiments with the small arches, the testing to destruction was effected by weighting the arch at the crown only, and the tendency of the haunches to lift was counteracted by loading them. These conditions do not fairly represent those occurring in actual practice, and the coefficients deduced from them require modification.

A step, although a small one, was made in the application of concrete to the building of arch bridges, by the erection of the first of that type in the United States. It was a road bridge over a creek in Philadelphia, and consisted of two spans of 25ft. 6in. each, and a rise of about one-fourth of the span, which is an unusually large ratio in such structures. The depth, 2ft. 6in., of the voussoirs at the crown was also large, as will be seen on comparison with other existing examples. It is possible that as the bridge was the first of its kind in the country, extra precautions were taken to ensure its strength and stability. As a further element of safety, wire nets with meshes of 1¼in., and a diameter of wire of ¼in., were inserted throughout the concrete at every 2ft., both horizontally and vertically. A further advance was made in the same direction by the construction of the compound concrete and iron arch bridge over the river Neutra at Neuhäusel in Hungary, in which thirteen skeleton girders or frames were used. There were six spans in this bridge, each of 55ft. 6in., and a rise of one-fifteenth of the span—a very different proportion to that previously mentioned. The thickness of the arch rings at the crown was but 12in., increasing to 1ft. 6in. at the springings. Another increase in the span of bridges of this description is to be found in the one crossing the Upper Danube near Rechtenstein, Wurtemburg, which consists of a couple of arches wholly of concrete, 75ft. 6in. in span, with a rise of one-ninth of the span, and a depth at crown and springing of 2ft. and 3ft. respectively. It may be noted that, notwithstanding the somewhat insignificant dimensions of this bridge, the system of hinge joints was adopted. An open joint was left at the crown and near the springings, with sheet lead interposed in the joint. It is very doubtful whether, by this contrivance, the pressure actually brought upon the joints was not considerably greater than that of 86 lb. to the square inch originally calculated and allowed for.

As the maximum span of any particular type or design of bridge, independently of all other considerations, is regarded, at any rate in an engineering point of view, as the best "record" until it is surpassed by some other, so the progress of concrete arch bridges advances in proportion to the spans successively achieved. A road bridge at Erbach in Wurtemburg raised the standard or criterion of dimension to 105ft., with the small rise of barely one-eighth and a thickness at the crown of 1ft. 8in. and at the abutments of 2ft. 3in. It should be borne in mind that with a material like concrete, the striking of the arch—always an anxious moment with the engineer and architect—whatever may be the material of which the arch may be built, is attended with more than ordinary risk. The flatter the arch the greater the liability to deformation, which means serious cracks in the material. As a precaution against the occurrence of these cracks in the Erbach bridge, flat asphalte joints were introduced at the crown and springings. A very similar structure in the neighbourhood of Dresden has a still greater span of 114ft., and another over the adjacent river Weisseritz of 142ft. Both these latter are skew bridges, the former with an angle of skew of 18¼ deg., which is one of the sharpest we can call to mind, and increases the span on the square from 56ft. to the dimension already given.

The greatest achievement in the construction of concrete arch bridges appear to have been reached in the erection of the new road bridge over the Danube at Munderkingen, the building of which was commenced just three years ago. The span is 164ft., with a rise of one-tenth of the span, a very safe and judicious proportion, and a depth at the crown of 3¼ft., increasing to 3½ft. at the abutments, which is less than the same ratio of the thicknesses of the arch in the examples previously given. An elaborate system of a dozen iron joints is distributed both at the crown and springings throughout the entire cross section of the arch, which practically divide the arch into two separate and distinct segments so far as the abutments are concerned. It may be stated, in connection with the subject of our article, that some very interesting and valuable experiments have been recently undertaken by the Austrian Association of Engineers and Architects. The researches of the members embrace the question of arches of masonry, of brick, and of concrete. Omitting smaller specimens, their testing and fracture, a concrete arch rib was built with a span of 75ft., a width of 7ft., a rise of one-sixth the span, and a depth at the crown of 1ft. and of 2ft. at the springings. At the end of a couple of months the centres were struck, although, as is usual with arches of stone and brick, they had been previously eased. The arch was then loaded to the breaking point, which was reached with a load of 3½ tons per running foot. So far as the span, rise, and some of the other dimensions of the arch rib thus experimented upon might be relied upon to furnish trustworthy data for calculations for the strength of similar larger structures, there is no objection to be taken; but there is, nevertheless, a great difference between an arch rib and an arch of some ten times its width. A thin rib has little or no lateral rigidity. In a word, it does not possess, or only to a small extent, that element "mass" which has been assumed to be indispensable to enable this valuable constructive material to utilise its full strength. The introduction of wire netting in the body of a concrete arch, which does not appear to be necessary unless the arch be very flat, thereby causing the haunches to spread, belongs to the Monier method of building arches. It is supposed to counteract the tendency of the arch to split at the intrados at the crown, and at the extrados at some point of the haunching, thus bringing a tensile stress upon or near the soffit of the arch rings at the crown. Bridges of this design have been built in Switzerland, with spans varying from 62ft. to 122ft. Whether the wire netting, which is somewhat analogous to the hoop iron used in ordinary brickwork, fulfils the purpose intended, is open to doubt. The principal objections to all compound structures are that, in the first place, it is impossible to be certain that the two distinct materials act together as one, and even if they did, what portions of the total stresses do they each undergo? Secondly, that the bond between the wire and concrete would be worth very little; and thirdly, that chemical action, and consequently corrosion, would be set up between the two materials. There is no evidence from actual experiment, or from bridges which have been built now for some years, that any of these objections possess any validity worth consideration. It has been alleged by some who are haunted by that engineering *bête noire*—contraction and expansion—that the difference in the coefficients of the two substances might lead to cracks and dislocations in the concrete; but having regard to the fact that the two coefficients are exactly equal to six decimal places, we think the remaining difference may be neglected with perfect safety. From the examples we have adduced—and there are many others as well—it may be fairly anticipated that concrete arch bridges have a future before them. Portland cement or its equivalent is now manufactured largely on the Continent and in still more distant localities, and the other ingredients of this useful compound constructive material can be procured almost anywhere.

Royal Institution.—On Tuesday next, April 14th, Professor James Sully will begin a course of three lectures on "Child Study and Education." On Thursday, April 16th, Professor Dewar will begin a course of three lectures on "Recent Chemical Progress;" and on Saturday, April 18th, Professor W. B. Richmond, R.A., will begin a course of three lectures on "The Vault of the Sixtine Chapel." The Friday evening meetings will be resumed on April 17th, when Professor G. Lippmann will deliver a discourse on "Colour Photography."

Society of Arts.—The next course of Cantor Lectures will be delivered by Professor Henry A. Miers, M.A., on Monday evenings, April 13th and 20th, the subject being "Precious Stones." The lecturer will deal with (1) The properties which make precious stones esteemed among minerals; (2) the properties by which precious stones are recognised; (3) the distinction of stones which may be confused, as garnet and ruby, jacynth and cinnamon-stone, zircon and lux sapphire, garnet and olivine, tourmaline and diopside, &c. The lecture will close with some remarks on artificial stones. Mr. James Swinburne will deliver a course of Cantor Lectures on "Applied Electro-Chemistry," on Monday evenings, April 27th, May 4th, 11th, and 18th. The papers arranged for meetings after Easter are:—April 15th, "Early English Organ Writers," by Mr. Burnham Horner; April 22nd, "The Perfected Photochromoscope and its Colour Photographs," by Mr. F. E. Ives; April 29th, "Fruit Drying or Evaporation," by Mr. E. W. Badger. Papers at subsequent meetings will be read by Captain Abney on "Orthochromatic Photography"; by Mr. Hudson Maxim, on "High Explosives and Smokeless Powders"; and by Mr. E. W. Moir, on "Tunnelling by Compressed Air."

THE INSTITUTION OF NAVAL ARCHITECTS.

WE give this week the principal portion of Mr. Stromeyer's paper, read on Thursday week. The original contains a large number of tables, but we do not think their reproduction is necessary; they refer to individual experiments. All those portions of the paper dealing with the principles involved we have reproduced. The discussion which followed was brief, and of little interest. Mr. Schonheyder held that the system proposed was not as good as the method of measuring by a meter or weir. Mr. Milton said that whatever might be thought in other respects, Mr. Stromeyer was at all events the first to suggest a possible method of measuring the great quantity of condensing water used at sea. Mr. Thom held that Mr. Schonheyder had overlooked the circumstance that meters could not be used at sea, and that Mr. Stronmeyer's methods were, as he had proved by personal experience, very accurate.

Mr. Seaton's paper we give in full in another place. It deservedly attracted a good deal of attention, but in many ways the discussion carried those who heard it and are no longer young back to the past—to the old days when steel shafts were first used at sea, and Mr. David Kirkaldy cut more than one broken shaft up and tested and reported upon it. Mr. Milton was quite right when he said that there had been papers written and read on the subject before. He held that this was the first that showed that the cause of so-called mysterious fractures could be révealed by the microscope. He then referred to the work done by Professor Arnold, of the technical school at Sheffield, and by Dr. Sorby. The shaft—the subject of Mr. Seaton's inquiry—appeared to be of very indifferent quality, and yet, curious to say, it had passed severe mechanical tests. Mr. Milton could not agree with the author that boring out a shaft made it stronger by taking away that part of the metal likely to have been badly worked because it was in the centre of the ingot. In some cases the best part of the shaft was inside and the worst outside. Mr. Hall, of Sheffield, did not think this shaft had given exceptionally good results considering its quality. He knew that ingots would pipe, but the piping was of no consequence, because the piped part was cut off the ingot. The sulphur and carbon collected in the pipe, because that part remained fluid longest. As to annealing, good steel could not be spoiled by it, and forgings needed annealing just as much as castings did. As to impurities and their effect, he could assure his hearers that large quantities of sulphur might be in a casting without injuring it. But if the steel casting were put in an annealing furnace it would be ruined, becoming extremely brittle, a fact which bore out Mr. Seaton's statement that it did not do to rely too much on chemical analysis. Mr. Seaton had expressed doubts as to the soundness of the theory of fatigue of metals, but he—Mr. Hall—had read a paper some years ago on "Fractures in Steel Shafts." He referred to cases in which shafts had worked well for years and then broken, and he could only think that fatigue was the cause of failure. He thought that the microscope had a great future before it for investigating steel.

Mr. Thornycroft, after a few complimentary remarks, asked if the microscope had been employed on gun metal, and if so with what results?

Mr. Ellis, of Sir J. Brown and Co., said his company had been using the microscope for the examination of steel for years, and he could bear out what Professor Arnold had said in his report as to its value. Mr. Ellis did not think that Mr. Seaton's pictures need alarm any user of steel, because it must be remembered that, although the pictures were tolerably large, the section of steel which they illustrated was very minute. They were like drops of water in the oxyhydrogen microscope on a screen which showed hideous monsters. There was usually shown at the same time a drop of pure water that comparisons might be drawn; and he suggested that Mr. Seaton should add a section of pure steel such as that shown on a photograph, which he begged those present to examine as a good and fair specimen.

Mr. Manuel, of the P. and O. Steamship Company, said that as it happened that during the last fourteen years they had been using steel shafts and had never broken one, nor found a flaw, he did not propose to begin using a microscope now. However, he had used the microscope himself years ago. In twin-screw shafts the stresses are different from those occurring in single shafts. He had in all put in 110 steel shafts; one of them had run nearly 1,000,000 miles, and was still good. He did not believe in boring out shafts, because they did not break from the inside but from the outside. The microscope only dealt with very small quantities of metal, and he thought it was hardly fair to judge of the quality of a whole shaft from an infinitesimal portion of it.

Mr. Archibald Denny said that Mr. Manuel's shafts did not break because he made them very strong—stronger than Lloyd's or the Board of Trade asked for. He fully believed in boring out shafts. He would like to see all shafts bored out.

Mr. Matthews, of Sheffield, after denouncing the quality of the shaft tested by Mr. Seaton, said that the proper way to make a steel shaft was under the hydraulic press. The hammer might leave a shaft hollow and unsound in the middle, but the squeezer stood no nonsense. The metal had to go together solid. It was the practice of his firm—Messrs. Whitworth and Co.—to anneal a straight forging, turn it in the lathe, and then anneal it again. They produced the collars at the end by upsetting the metal so as to get the fibres running round into the flange from the shaft. He believed in the doctrine of fatigue. Mr. Manuel's shafts did not break because they were all made with the best Swedish iron.

Professor Arnold described at some length the process of getting up specimens for the microscope. He said it reminded him of the washing away of a macadamised road by heavy rain, when the dirt was washed oft and the small stones stood up like nodules. He then endeavoured to give his hearers a notion of what a molecule was like. He thought that intercrystallisation might explain the effects of annealing. As to fatigue of metals he would like to know what the word meant. His notion was that it meant the loosening of the crystals among themselves. Mr. Matthews had spoken of homogeneous metal, but was there such a thing? Certainly steel shafts were not homogeneous, but composed of an intimate mixture of steel and iron particles. The only approach to homogeneous steel had far too much carbon in it to permit its use in a screw shaft.

Mr. Seaton replied on the whole paper; but he had of course very little to add. As a rule, the writer of a paper keeps back nothing; he puts all he knows on the subject into it, and as Mr. Seaton had practically no criticisms to answer, his reply was all the shorter. As to tests, both Lloyd's and the Board of Trade had tested specimens prepared by the steel makers, and not bits cut out of the shaft itself; he would utilise drillings from holes bored in the shaft for testing. In reply to Mr. Thornycroft, he said that he took little interest in testing gun-metal but much in high strength bronze or alloys, by which it was possible to get very light and strong machinery. Mr. Matthews' remarks about the press and the hammer reminded him of the story of the fox who had lost his tail. Everyone knew why Whitworth's used a press. He could assure Mr. Matthews that very excellent shafts were made under the hammer. As for Mr. Manuel's shafts, they were so big and they ran at such slow speeds, that they would probably have stood just as well if they had been made of good cast iron.

Mr. Seaton's paper was followed by that of Mr. Stromeyer, and then came Mr. Kinghorn's paper, given in our last impression. With the evening proceedings we dealt fully last week. It will be remembered that the interest centred in Professor Watkinson's lecture on water-tube boilers.

THE INSTITUTION OF CIVIL ENGINEERS.

THE TAMPICO HARBOUR WORKS MEXICO.

AT the ordinary meeting on Tuesday, the 31st March, Sir Benjamin Baker, K.C.M.G., the president, in the chair, the paper read was on "The Tampico Harbour Works, Mexico," by Dr. E. L. Corthell, M.A., M. Inst. C.E.

The port of Tampico was situated near the mouth of the river Pánuco, which flowed into the Gulf of Mexico at a point about midway between the port of Vera Cruz and the mouth of the Rio Grande. The volume of discharge at high water in the Pánuco was about 150,000 cubic feet per second, and the cross-sectional area of the river between the mouth and Tampico, a distance of seven miles, was about 25,000 square feet. At very high water the slope was 7in. per mile, and the average width about a quarter of a mile; the channel was about 30ft. deep, the 20ft. channel being about 700ft. wide.

The diurnal tides in the Gulf of Mexico, as shown by a diagram giving one year's continuous tidal record, had an average range of about 15in., but at times ranges of between 2ft. and 2½ft. had been observed. The river water was generally clear, but during floods it became fully charged with sediment, about 18 per cent. of which was siliceous material and the remainder clay. The river entered the gulf in a single channel, there being no delta formation; and the bar in the sea had not altered its position for many years. During floods the river by its sedimentary deposits had caused the bar to encroach upon the gulf, but at low water the waves and currents pushed the bar back to its former position. The direction of the currents in the gulf was northerly under the influence of the Gulf Stream, but the prevailing winds formed much more powerful southerly currents, which were effective in removing the bar. The general condition of the bar for seven years previous to the construction of the works was described, the average depth of water on the bar during this period being 9·06ft. Borings into the bar showed generally fine sand to a depth of 20ft. or 22ft., and then clay.

It had been decided to deepen the bar by means of two parallel jetties, placed 1000ft. apart from centre to centre, and extending from the shore into a depth of about 24ft., or a distance of about 6700ft. The Mexican Central Railway Company, by which the works had been constructed, had extended its line from Tampico to the mouth of the river; and a trestle or pile bridge had been built to carry two lines of railway in connection with the railway on shore, and had been extended, by means of an overhead swinging pile-driver, in advance of the work. It was at the shore 8ft., and at the sea end of the jetties 12ft. in the clear above mean high tide; and from it the mattresses had been suspended during construction and were dropped into the sea. The brushwood for the mattresses had been brought to the site by rail or by barges, as was also the stone for sinking the mattresses. The brushwood was inferior to willow, and after sinking the compression amounted to nearly 50 per cent. Heavy limestone, weighing about 170lb. per cubic foot, had been used, the quarry being about 78 miles from the work, on the line of the Mexican Central Railway. The piles were brought from the Gulf ports of the United States, and were of southern pine; those used under the stringers of the trestle were generally creosoted with 12 lb. of oil per cubic foot.

The amount of stone required to sink and hold down the mattresses was much greater than that used for the same purpose at the mouth of the Mississippi on account of the much larger amount of sediment at the latter place. The north jetty particularly was much more exposed to wave forces. At the Mississippi it required only 0·075 cubic yard of stone to one cubic yard of mattress, while on the north jetty at Tampico it required 0·440 cubic yard. Communication between the south and north jetties was maintained by a barge on which rails were laid, and a steam tug. A locomotive was placed on the south side to work the wagons, which were 36ft. long over all, with a capacity of 15 tons each. The total amount of rock used, up to December 31st, 1892, was 373,048 cubic yards, of brush 390,532 cubic yards, and of pine piling 253,347 lineal feet, of which 57,260ft. were creosoted. The total amount of pine timber was 2,018,950ft., board measure.

The severity of the waves rendered it necessary to consolidate the north jetty and the sea end of the south jetty, with an abundance of rock having easy slopes. The rock was entirely of rubble, of a size not exceeding three cubic yards. No dimension stone and no concrete had been used. The crown of the work was laid up with rough stone, and was rounded, and had easy slopes, like that of the jetties used at the mouth of the Maas, in Holland.

The total cost of construction and maintenance up to December 31st, 1894, but including the real estate purchased, the extension of the railway to Tampico, the construction of commercial wharves and docks, interest on bonds and other expenses, was £617,543 6s. 5d.

The development of the channel had been very satisfactory; and was shown by comparative longitudinal profiles and cross-sections. The effects of the work upon the river channel above the jetties were also discussed. The channel had shoaled for a considerable distance, but when the channel through the bar had developed the river channel had deepened. A peculiar condition had been found in the bar; the development of the channel had been delayed by a formation caused by numerous wrecks of vessels lost upon and sunken in the bar.

The results were given of a flood in 1893, together with diagrams indicating the forces at work to improve the channel; these observations also showed the discharge of sediment and the amount of material excavated in the channel during the flood; the former being 203,000,000 cubic feet, and the latter about 32,500,000 cubic feet. At this flood the inner bar, where the wrecks had been found, had been entirely removed, and a deep and wide channel produced with a least depth of 21½ft. at the sea end of the jetties, but with a depth everywhere else in the jetty channel of between 24ft. and 30ft. The hydrographic conditions before the works were begun, and after they were completed, were shown on two charts, one of May, 1890, and the other of January, 1895. On the latter the channel had a least depth of 24ft., and an average width at that depth of 680ft.

The navigational conditions before the works were begun, and after they were completed, were dealt with, and a table was given showing the increase in tonnage and the value of freights between 1885 and 1894. The tonnage in 1890 was 30,000, and in 1894, 192,000.

The important commercial advantages of the port were briefly stated; it had a deep and safe entrance channel and a land-locked harbour. Communication with the entire railway system of the country had been already established by two routes, and a third line, direct to the City of Mexico, was projected by the Mexican Central Railway Company.

THE INSTITUTION OF JUNIOR ENGINEERS.

COAL HANDLING PLANTS FOR STEAM GENERATION.

AT the meeting of this Institution held at the Westminster Palace Hotel on March 6th, Mr. H. J. Young in the chair, the paper read was on "Coal Handling Plants for Steam Generation," by Mr. Charles H. Fletcher, Member.

The subject, the author stated, had received but little attention at the hands of English engineers, but, owing mainly to the exertions of Mr. C. W. Hunt, of New York, its importance had been fully recognised in the United States, where many applications of special plants had been installed. Descriptions were given of appliances used for hoisting, carrying, and delivering the coal consumed in the generation of steam at various large power and locomotive coaling stations, a number of lantern slides being used in illustration.

In the past the expense of handling coal and ashes had been regarded as a minor one, but, through the more exact knowledge of thermo-dynamics and the perfection of modern steam raising appliances, the saving it had become possible to make in this direction had become relatively more prominent, so much so that in some cases the buildings, boilers, and coal storage had been specially arranged to decrease the daily operating expenses to the smallest possible amount.

The first installation referred to was that at the third district station of the Edison Electric Illuminating Co., of Brooklyn, where the work to be done was to take the coal from wagons, carry it to storage bins above the boilers, weigh it, deliver it to the furnaces, and to remove and dispose of the ashes. The coal is dumped into a hopper under the side walk, from whence it passes through a filler into a conveyor consisting of a series of buckets pivoted in a double chain, the whole system being carried on self-lubricating wheels running on a track, changes of direction being made by running around curves; this, together with the driving, being effected by pawls rolling on pins in the chain, entirely doing away with sprocket wheels and the wear and noise inherent to them. The driver was operated by an electric motor, but other methods, such as a rope drive, leather belting, and directly connected engines, were illustrated and described as suitable. The ashes were removed by the coal conveyor, a separate rotary filler delivering a measured quantity of ashes to each bucket.

At the Ridgewood pumping station of the Brooklyn Waterworks, with a total pumping capacity of 110 million gallons per twenty-four hours, the coal is delivered in railway cars, dumped into a hopper below the track, and then carried by a conveyor to a storage building holding 4000 tons. For carrying from the storage to the boilers, a system of tracks and cars are used, the former being arranged at a convenient distance from the boilers, and the latter designed to make the labour of filling them with coal and firing from them the least possible.

The Brooklyn Heights Railroad Company was next referred to. Here there were, at the Kent-avenue Station, thirty-six Babcock-Wilcox boilers, on two floors. The coal was taken from vessels by a steam shovel, holding about a ton, and lifted by a conveyor over 100ft. vertically, carried horizontally in two directions at right angles, and stored in a pocket holding 6000 tons, and situated directly over the boilers, so arranged that the coal could be weighed and spouted to either boiler-room floor, at the proper place.

The 12,000-horse power for operating the street railways in the southern part of Brooklyn was supplied from a station at the foot of Fifty-second street. The coal was received from vessels lying at the end of a pier 800ft. long, and hoisted by a steam shovel, movable on a trestle, the hoisting engine taking steam from the main boilers 800ft. distant. From the elevator the coal was taken by cars along a cable railway, built on trestles, to a storage building of a capacity of 8000 tons, and situated near the boiler-room, but separated from it by a water tank 90ft. wide. The lower line of a conveyor passes under the storage, then up over a single-span steel bridge above the tank, and carries the coal to the boiler-room. Four men only are required for operating this plant. By its introduction the cost of handling, including all expenses and interest, was reduced from 1s. 1½d. to 2d. per ton. Motive power was supplied by a steam engine specially designed to obviate damage by frost; the taking-up of the wear in the brasses was effected by a set screw in communication with a chamber filled with steel balls of varying diameters.

Various other power stations, and a number of locomotive coaling plants were illustrated. As an example of the latter, in the Philadelphia and Reading Terminal Railway, the problem was to store 500 tons of coal in a building in such a manner that it could be easily drawn into locomotives, and also at the same time to supply them with sand and water, and dump ashes.

The necessity of careful design and good workmanship was dwelt upon. In spite of the character of the use of such machinery, it was found to be a positive economy to pay due regard to these points, durability and freedom from breakdown fully justifying care and expense entailed in the first instance.

THE DOVER UNDERCLIFF.—On Wednesday last, Sir Edward Leader Williams, M. Inst. C.E., opened on behalf of the Board of Trade, an inquiry concerning the effect which the proposed Dover Undercliff Reclamation Scheme is likely to have upon the interests of navigation and the coast and foreshore east of Dover. The scheme has no opponents. It is admitted on all hands that as far as navigation and the preservation of the foreshore is concerned, the reclamation will have a most beneficial effect; and seeing that the great National Harbour will in the course of years monopolise the present sea front, it is most desirable that a new sea front should be provided beyond, so that Dover should not lose its attractiveness as a seaside resort. The promoters have arranged with the War-office and the Admiralty, and all points where the Undercliff scheme could possibly clash with the national harbour have been settled. The inquiry is therefore confined to the probable effect of the scheme on the coast line beyond Cornhill Coastguard station. The sea has at different times made great havoc there. Within the memory of people living there was a road under the cliff to St. Margaret's, with gardens and cottages. They have gone. At the present time the sea at high water washes up to the newly exposed chalk, from which all the footing has been washed away, and the Cornhill Coastguard station and the South Foreland lighthouses are distinctly threatened.

THE NEW WATERLOO BRIDGE OVER THE RIVER NESS AT INVERNESS.

The recently opened steel lattice-girder bridge over the river Ness at Inverness replaces and occupies the site of the old wooden structure known as the "Black Bridge." Built some ninety years ago, the Black Bridge successfully weathered many storms and gales, and came unharmed out of the great flood of 1849, which proved fatal to the grand old stone bridge at Inverness, whose site is now occupied by the great suspension bridge. Tradition has always maintained that the fall of the Black Bridge would be occasioned by a white horse; but the old structure has now disappeared bit by bit under the hands of the workmen pulling it down, and neither the prophesied collapse nor its connection with the white horse has proved its end, as believers in Coinneach Odhar—the Brahan seer—always held.

For some time past the Black Bridge has given signs of decay, whilst its width was found too narrow for the growing traffic of the thriving capital of the Highlands of Scotland, and in 1894 the Town Council of Inverness decided to pull it down and erect on the site a more commodious structure in accordance with the latest and most approved engineering practice. In December of the same year, plans having been prepared, tenders were sought with the following results:—

	£	s.	d.
The Rose-street Foundry Company, Inverness	6,985	10	0
Stockton Forge Company, Stockton-on-Tees	7,098	6	0
Inverness Foundry Company	7,131	0	0
Messrs. Crossley, Tilburn, and Company, Glasgow	7,400	6	8
Messrs. Somervail and Company, Dalmuir	7,541	16	6
Cleveland Bridge and Engineering Company, Darlington	7,725	0	0

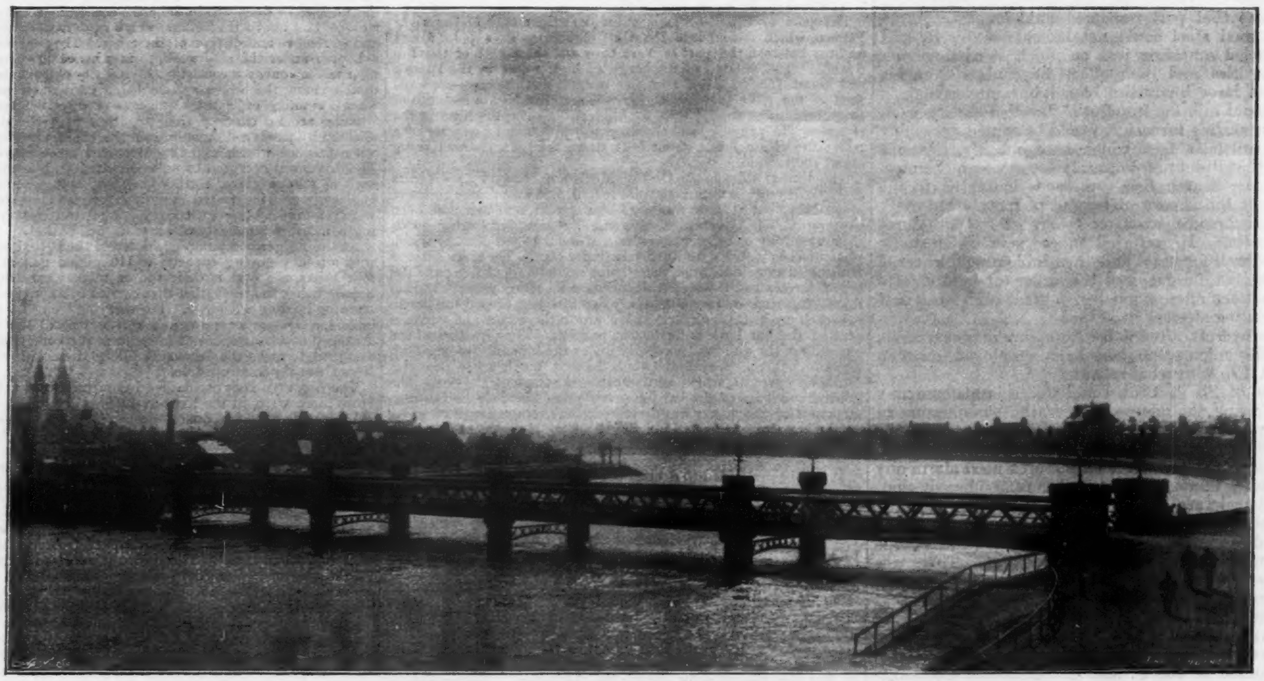
Messrs. P. and W. McLellan, Glasgow	7,957	15	7
Messrs. George Lawson and Sons, Edinburgh	8,207	18	6
Messrs. Head, Wrightson, and Company, Thornaby-on-Tees	8,685	7	10
Arrol's Bridge and Roof Company, Glasgow	8,771	16	8
Teeside Iron and Engine Works Company, Middlesbrough	8,927	12	5
Messrs. Murdock and Cameron, Glasgow	8,952	0	0
Messrs. Hanna, Donald, and Wilson, Paisley	9,333	0	0
Messrs. Charles Brand and Son, Glasgow	10,081	3	3
Messrs. Handyside and Company, Derby	10,916	6	1

The offer of the Rose-street Foundry Company, of Inverness, was accepted, and that concern has now carried the work to successful completion.



THE NEW WATERLOO BRIDGE OVER THE RIVER NESS AT INVERNESS

The site of the bridge is between Grant-street and Waterloo-place, the total length of the structure being 350ft., made up of five spans of 71ft. 3in. each from centre to centre of piers. Massive stone abutments at either end form connection with the banks, while four piers, each consisting of a pair of cast iron cylinders, filled with concrete and stoutly braced together, are founded in the river. Each cylinder is surmounted by a cast iron pilaster of ornamental design, carrying a well-proportioned lamp-post, the style adopted being of the castellated Highland order, well in keeping with the surroundings of the structure, and presenting a very pleasing and imposing appearance. The pilasters on the abutments are of stone, also surmounted by lamp-posts. The main girders, which are two in number, are spaced 29ft. 6in. from centre to centre, permitting an 18ft. roadway, flanked on either side by a footpath 5ft. in breadth.

Turning now to examine the structure in greater detail, the foundations were effected by means of cast iron cylinders 7ft. diameter at and below the bed of the stream, and 6ft. diameter at the level of the roadway. They were cast in 4ft. lengths of 1¼in. metal throughout, being bolted together by internal flanges stoutly stiffened by feathers between each bolt hole. The obstruction to the waterway caused by the piers of the new bridge is almost exactly that of the numerous massive piles of the old bridge, so that the same waterway was secured without increasing the distance between the abutments. The cross bracing connecting the cylinders was 3ft. 8in. and 2ft. 4in. deep at the ends and centre respectively, and was composed of a straight upper member of 8in. by 6in. by ½in. tee bar; and a curved lower member of the same scantling braced together by a double system of 3in. by 3in. by ⅜in. angles, placed back to back, secured to each other by one rivet at the junction and by two rivets at each end, where connection is made with the upper and lower flanges respectively. Connection is formed with each cylinder just beneath the cap by a pair of 4in. by 4in. by ⅜in. angles, and a plate 3ft. 8in. by 1ft. 7in. by ⅜in.

The sinking of the cylinders calls for no special remark, save that some trouble was experienced owing to the nature of the bottom; eventually, however, after sinking through water-logged gravel, a bed of fine sand was entered, in which a satisfactory foundation was made. The excavation inside the cylinder was performed by means of steam grabs, and, as soon as the cylinders were sunk to the required depth, divers descended and levelled the bottom, laying a flooring of neat cement in bags. Before ascending the divers slit the bags open. Four feet of concrete was then deposited in the water by a shoot, and four days later the cylinders were pumped out, and filling continued, as specified. On completion of sinking the cylinders were filled with 5 to 1 concrete, composed of three parts of washed shingle, two parts of sand, and one part of Portland cement, care being taken that "whenever work was suspended for a time the surface of the concrete must be left covered with 6in. of water, which must be removed before any more concrete is put in." The iron employed in the cylinders was specified to be best grey metal, a bar of which, 2in. by 1in. on 3ft. bearings, should be capable of sustaining a load of 27 cwt. at the centre, and bear a deflection of at least ¼in. without fracture.

Turning now to the steel work and the superstructure, the main girders are 7ft. 6in. in depth from back to back of channels of the upper and lower booms respectively. Each boom is composed of a pair of 12in. by 3½in. by 3½in. by $\frac{7}{16}$in. channels, spaced 12in. apart from back to back, with 20in. by ⅜in. plates. The cross girders are spaced 7ft. apart from centre to centre, have a depth of 2ft. and 1ft. at the centre and ends respectively—measured from back to back of angles—and are built with a pair of 4in. by 4in. by $\frac{9}{16}$in. angles, connected by a ⅜in. web, forming both top and bottom booms, both being curved. The lower flange is made up with a 10in. by ⅜in. plate, whilst the web is stiffened by 3in. by 3in. by ⅜in. angles, running its entire depth and made up in the middle with ⅜in. packing to save joggling over the 4in. by 4in. by $\frac{9}{16}$in. angles of the upper and lower booms. The longitudinal girders or stringers, which are spaced 4ft. 6in. apart from centre to centre, and have a total length of 6ft. 10½in., have a uniform depth throughout of 1ft., and are formed of a pair of 3in. by 3in. by ⅜in. angles, both for top and bottom booms, connected by a $\frac{5}{16}$in. web plate, junction being made to the cross girders at either end by means of 3in. by 3in. by ⅜in. angles, packed by ⅜in. packing, to avoid joggling.

The floor plates are buckled, being 7ft. by 4ft. 6in. by ⅜in., and are secured to the cross girders and longitudinals by ¾in. diameter rivets, with a pitch of about 4in. to suit the spacing. Over the cross girders cover strips 17ft. 11¼in. by 8in. by $\frac{5}{16}$in. run on the upper surface of the buckled plate joints. The footpaths are carried on similar buckled plates, supported at each end by a longitudinal 2½in. by 2½in. by ⅜in. angle, and jointed transversely by means of a 5in. by 2½in. by ⅜in. tee bar. The edge of the curb is formed by carrying up A ¼in. plate 1ft. 3in. deep from the end longitudinal girder, and stiffening it at its upper extremity by a 3in. by 3in. by ⅜in. angle, the upper leg of which is turned in towards the main girder. At the inner side of the footpath a 7½in. by ¼in. plate connects the 2½in. by 2½in. by ⅜in. angle, carrying the buckle plate with a 2in. by 2½in. by $\frac{5}{16}$in. angle at the surface of the footpath, which carries the fencing.

Turning now to the bracing of the main girders, which is a double system of triangular bracing, strut No. 1 is formed of a pair of tee bars 6in. by 3in. by ⅜in., connected at each end by an 8in. by $\frac{5}{16}$in. plate, and braced together throughout their length by a single system of 2½in. by ⅜in. flat bars placed on alternate sides. Struts No. 2, 3, and 4 are similar in all respects, save that the tee bars are 5in. by 3in. by ⅜in.; while in strut No. 5, 3in. by 3in. by ⅜in. angles are employed in place of the tee bars. The ties—with the exception of that numbered 5, which is formed like strut No. 5, of 3in. by 3in. by ⅜in. angles braced together by 2½in. by ⅜in. flat bars, and with $\frac{5}{16}$in. plates at each end—are formed of flat bars with the following scantlings for ties Nos. 1, 2, 3, and 4 respectively, viz., 7in. by ½in., 6in. by ½in., 5in. by ½in., and 4in. by ½in. The junctions of the main bracing are made in all cases inside the booms of the main girders, and call for no special remark. The end plates of the main girders are 7ft. 6in. by 1ft. 8in. by ⅜in., the end posts being made up with and stiffened by 3in. by 3in. by ⅜in. angles and an internal ⅜in. plate. The main girders are carried throughout on cast iron bed-plates, those for the fixed ends at the abutments being 1½in. thick in the body, with a 2in. projection 2in. wide at the bottom, and secured to the masonry by a pair of 1¼in. Lewis bolts, the connection between the girders and the bed-plates being formed by four 1in. bolts passing through the lower horizontal leg of the channel bar. Over the piers double bed-plates 3ft. 9in. by 2ft. 8in. are employed, with a 2in. by 2in. projection running across the centre at the bottom; the fixed end is held down by four 1in. bolts, while the free end of the next girder has no attachment to the bed-plate, but simply rests upon it. The bodies of these bed-plates are 2½in. thick, and all bearing surfaces are planed. The expansion joint in the floor-plate for the roadway is formed by a 9in. by ⅜in. plate riveted to the last cross girder of the free girder, and sliding over the prolongation of the end buckle plate of the fixed end. A similar arrangement holds in the expansion joint in the floor plate for the footpath, except that the sliding plate is 1ft. 3in. by ⅜in., the 2½in. by 2½in. by ⅜in. angles of the free end having elliptical holes to allow for movement.

All steel used throughout the structure is Siemens-Martin open-hearth material, having an ultimate tensile strength of 29 tons to 32 tons per square inch, with an elongation of at least 20 per cent. on an 8in. length. The customary bend test requirements being exacted, by which strips 1½in. wide should bend to a curve whose inner radius was 1½ times the thickness of the sample under manipulation, either when cold or after tempering in water at 82 deg. Fah. The rivets employed in the work had an ultimate strength of 26 tons to 32 tons per square inch, with an elongation of at least 25 per cent. on an 8in. length, the same bend tests being required. The specification specially requires that no material should be worked when at a temperature of from 600 deg. to 400 deg. Fah., the dangerous limits known as "blue heat." The highest class of girder work was exacted throughout the contract; all edges being planed and every hole being drilled. Hydraulic riveting was, whenever practicable, employed.

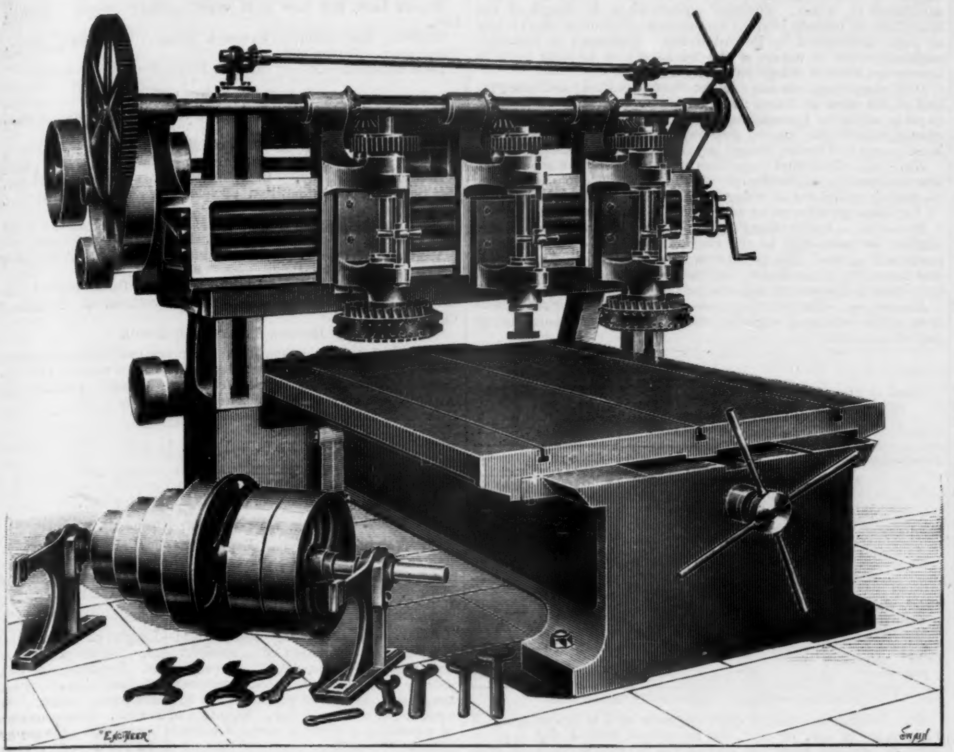
The stone used in the structure is, with the exception of the girder blocks, freestone from Mason Haugh, a peculiarly hard specimen of the Morayshire freestone, the girder blocks of the abutments being of granite 4ft. by 3ft. by 1ft. 9in., dressed smooth on the top to receive the girders. The girder blocks on the piers are also of granite, 4ft. 1in. by 3ft. by 13in., dressed smooth on the top and nidged on all other sides, being bored to receive the four holding-down bolts and embedded in concrete. The cement used is Portland cement, of such fineness that the residue on a sieve having 2500 meshes per square inch does not exceed 5 per cent. by weight. A breaking stress of the cement gauged neat and after seven days was required to be not less 400 lb. per square inch, whilst mixed in briquettes with three times its weight of sand, a strength of not less than 170 lb. per square inch was specified after twenty-eight days. The cement used throughout the undertaking was composed of three parts of washed shingle under 2in. diameter, two parts of clean sand, and one part of Portland cement; the whole being turned over five times. The stone pilasters over the abutments were dressed and dabbed ashlar, with droved margins 2in. wide on each face.

The whole surface of the carriage-way and footways was covered with a mixture consisting of one-third part of bitumen to one part of Portland cement, laid on 1in. thick at the joints of the plates and completely filling the depressions. This was applied hot, and floated to the proper convexity in the carriage-way and to the proper slope on the footpaths, the whole surface, both of roadway and footways, being finally paved with Baltic redwood, thoroughly creosoted, in blocks 3in. across the grain by 4½in. deep, overlying a bed 1in. in thickness made up of thirteen parts of bitumen to one part of sand, combined whilst hot. The redwood blocks were set with strips of creosoted redwood, ¼in. thick and 3in. deep, between each two courses. All steel work received one coat of boiled linseed oil and two coats of oxide paint, the cast iron bed-plates and foundation cylinders being coated with Dr. Angus Smith's solution. The cylinder joints were securely rusted together before the concrete was put in. The total weight of mild steel and cast iron in the structure was 300 tons and 160 tons respectively.

The engineer of the bridge is Mr. John Allan Mackenzie, C.E., Burgh Surveyor, Inverness; with Mr. Murdoch Pater-

THREE-HEAD SURFACE MILLING MACHINE

MESSRS. G. WILKINSON AND SONS, KEIGHLEY, ENGINEERS



son, M.I.C.E., of the Highland Railway Company, as consulting engineer and arbiter.

The illustration we reproduce is from a photograph by Mr. Adam Cooper, Inverness, to whom we are indebted for its use. Further illustrations of the bridge in detail will be published in our next impression.

LARGE THREE-HEAD SURFACE MILLING MACHINE.

The machine illustrated above has been designed for milling the surfaces of cotton spinning frame ends and various other descriptions of work of a more or less simliar kind. The machine has three tool heads, and will mill longitudinally and transversely any article up 8ft. 6in. in length and 5ft. 4in. between the standards. The cross-slide will rise and fall 18in., similar to a planing tool, and it has an independent vertical adjustment to each tool of 2in. The bed is 10ft. long, by 3ft. 7in. across face, by 1ft. 5in. deep, with table 5ft. wide by 7ft. long, having a variable self-acting feed motion given it by a screw down the centre of the bed. It is operated by a double clutch motion at one end of the bed, and a lever is placed at the front side of the machine, where it is easily accessible for putting into gear. By pulling the clutch out of gear with the feed motion, and putting it into gear with the opposite clutch, it gives a quick return motion to the table 150 times the speed of the feed-traverse. The table is stationary when the clutch is in its middle position. An adjustment as to traverse can also be made by a star wheel at the opposite end of the machine. The cross-slide is tilted slightly so that the tools only cut in front, those behind just clearing the work. The outside tool-head will move far enough out of the way to allow a self-acting cross traverse of 3ft. 6in. to the middle tool-head, which has a cutter 5in. diameter and 1in. wide for flat surface and edge cutting, so that an L seating could be milled. The cutter-head discs are made with slots cut in at a proper angle, similar to a worm-wheel, and carrying straight pieces of $\frac{5}{16}$in. square tool steel which require no forging. The angle gives the clearance in front of the tool, and the end of the tool is ground slightly at an angle for clearing the back. The cutter-head discs are 12in. diameter from centre to centre of tools, and 3in. thick, the tools being each held by two nipping screws. The tool discs can be readily screwed on and off to admit a different cutter if desired. The driving cone has four speeds, 18½in., 15½in., 12½in., 9½in. diameter for a 4in. belt, the overhead driving gear being of corresponding dimensions. The machine was made by Messrs. G. Wilkinson and Sons, Keighley, and its weight is seven tons.

NEW SHIPPING—BRITISH AND FOREIGN.

The Peninsular and Oriental Company has in the recent order given out for new shipping, allotted a share of the work to other builders than Messrs. Caird and Company, of Greenock, who, up till lately, built all the company's new vessels. That this circumstance has no significance as bearing on the relationship between this great mail company and its well-tried builders at Greenock is shown by the announcement that Messrs. Caird and Company have just received an order from the Peninsular and Oriental Company for the construction of two first-class mail steamers, each of 8000 tons, and 11,000 indicated horse-power. The engines will be of the triple-expansion type, and both hull and engines will be similar to the India, now on the stocks, and which Messrs. Caird purpose launching on the 15th inst. The India is the largest vessel, as regards tonnage, ever built at Greenock. Though driven by single screw engines on the triple-expansion type, the distribution of power and smoothness of working is insured by the arrangement employed of having four cylinders fitted tandem fashion. With the order for the two new vessels, and one recently received for a twin-screw steamer of 8500 tons, Messrs. Caird and Company have now 32,500 tons on hand for the Peninsular and Oriental Company. Vessels for the same company are being built in other yards—one a twin-screw of 8500 tons, in the yard of the Palmer Company, of Jarrow; and another, the China, similar to the India, in the yard of Messrs. Harland and Wolff, Belfast. The India and China, and the two similar vessels just ordered, are each 500ft. long, of proportionate beam, and will carry 500 first and second-class saloon passengers. They are similar in type, but larger than the Caledonia, Australia, and Himalaya, now running on the Eastern services. The India and China will be ready for service during the coming autumn, and the two vessels now ordered will be delivered in time to commence running previous to the termination of the present mail contracts which expire in January, 1898. To the work already in hand in Clyde shipyards for German owners—notably in the yard of Messrs. C. Connel and Co., where three steamers of approaching 15,000 aggregate tonnage are underway for Hamburg owners — there falls to be added another steamer of 5000 tons, just contracted for by Messrs. Alexander Stephen and Sons, of Linthouse, to German account; three large steamers, each of 7500 deadweight capacity, are at present nearing completion in English yards for the Rickmer's line of Bremen. These facts, looked at in connection with the other fact that the shipyards in Germany are as busy as they can be with local orders, show that German owners are determined not only to keep a firm hold where they have already got a footing as rivals to Britain in the carrying trade of the world, but to secure a share in new trades as well.

The United Steamship Company, of Copenhagen, has placed an order with Messrs. Lobnitz and Co., of Renfrew—who have already built very extensively for the same owners—for two steamers, each of 2000 tons dead-weight capacity. Two steamers of the same dead-weight capacity and 15 knots speed have recently been contracted for with Clyde builders by a firm engaged in the West Indian and Central American trade. The new Continental Express Company, promoted by the Southampton Traders' Company, Limited, is understood to have negotiated with Clyde builders for the construction of three screw steamers of a novel form to be employed in the projected passenger and cargo service between Tilbury-on-Thames and Ostend. The vessels are to be built with three keels, on the principle devised by Mr. T. F. Hodgetts, formerly of the Indian Navy, and late Professor in the Royal Naval College, Prussia. From the central or ordinary keel the vessel's bottom springs away on each side in a concave curve towards the extra side keels, in the region of what, in ordinary ships, would be the lower turn of the bilge. This style of bottom, it is claimed, secures immunity from rolling, and combines with steadiness not only greater ease in steering and handling, but also, it is said, increased speed.

Trade and Business Announcements.—Messrs J. Kershaw and Co., of 38a, King William-street, London Bridge have, we understand, purchased the British and foreign patent rights in Moore's universal carving machine, and are now offering it to engineers for pattern-making.—Mr. Wm. H. Booth has resigned his appointment as managing engineer for Messrs. Le Grand and Sutcliff, artesian engineers, and has taken offices at 17, Shaftesbury-avenue. W. — Piccadilly-circus — where he will carry on business. — Messrs. John Shaw and Co., Maryhill Ironworks, Glasgow, have re-opened their office at 6, Lombard-court, London, E.C., and in future will be represented, both for the export and home trade, by the junior partner, Mr. Hugh Girvan.—Among new companies we find Henry Pooley and Son, Limited, registered with a capital of £100,000 in £1 shares, to acquire the business carried on by Henry Pooley and Son, at Albion Foundry, Liverpool, and elsewhere, to enter into a certain agreement, and to carry on the business of engineers, ironfounders, weighbridge, weighing machine, and scale makers, and repairers, &c. The subscribers are Messrs. H. Pooley, jun., Caithness-road, Liscard; J. S. Pooley, 7, Grafton-road, New Brighton; J. Chater, 223, Peckham Rye, S.E.; J. Hines, Lenzie, Dumbarton, N.B.; L. Jacob, 29, Braithwaite-road, Birmingham; J. Harris, 44, Braithwaite-road, Birmingham; and J. W. North, 33, Weld-road, Birkdale. The number of directors is not to be less than three nor more than five. The first are the first five subscribers. Qualification, 100 shares. Remuneration, as the company may decide.—W. Jessop and Son, Sheffield, inform us that from this date their London address will be No. 54, Cannon-street, E.C., and communications should now be sent there to them or to their agents, Messrs. Calvert, Harris, and Co., who continue to represent the firm as heretofore.

ASSISTANT-ENGINEERS IN THE ROYAL NAVY.

We have received so large a number of letters asking for information as to the nature of the examinations that candidates for the post of assistant-engineer in the Royal Navy will have to pass, that we publish the regulations as issued by the Admiralty in full. The examination papers are never published, but the syllabus indicates their characteristics very closely.

The following are the regulations for the guidance of candidates for direct appointments as probationary assistant-engineers in the Royal Navy:—

General Paragraphs applicable to all Candidates.

1. Candidates for direct appointment as probationary assistant-engineer in the Royal Navy must not be under twenty, nor over twenty-three*, years of age at the date of examination. They must produce a certificate of the date of their birth; or, in default, a declaration made before a magistrate by one of their parents or other near relative, stating the date of birth.

2. They must have attended the regular day engineering course—either civil, mechanical, or electrical—at a recognised college for technical education for not less than one year.

3. They must have been not less than three years under training in approved engineering establishments, and must produce satisfactory certificates of practical ability.

4. They must be British subjects, and must produce certificates of good conduct for a period of not less than five years previous to the date of application, signed by the heads of the schools and colleges at which they were educated, and of the engineering establishments at which they were pupils; if educated in part at home, certificates from a magistrate or clergyman to whom they were personally known must be produced for such period.

5. No candidate can be allowed to present himself for examination unless the certificates mentioned in the preceding paragraphs are considered satisfactory by the Admiralty.

6. Candidates who receive permission to present themselves for examination must attend, where required, for medical examination by Naval Medical Officers, and must be found physically fit to render them eligible for entry.

7. The number of appointments to be made in each year will be fixed by the Lords Commissioners of the Admiralty, and the list of candidates will be kept at the Admiralty.

8. Candidates for entry must send to the Secretary of the Admiralty certificates of ability to swim.

9. Probationary assistant-engineers will be confirmed at the end of twelve months' probationary time, if their conduct and qualifications are satisfactory.

10. In the event of the conduct and qualifications of any probationary assistant-engineer not being satisfactory during his twelve months' probation, or of his failing to pass satisfactorily at the final examination at the Royal Naval College—see par. 15—his commission will be withheld for six months, or for such period as may be determined by their Lordships.

A.—Paragraphs applicable to Candidates who take the Complete Admiralty Examination.

11. All applications for the forms to be filled up by candidates must be sent to the Secretary of the Admiralty, London, S.W., on or after the 1st of February in each year, and care must be taken that the forms, when filled up, are returned with the certificates of birth, training, and moral character, so as to reach the Admiralty on or before the 15th of May following.

12. The examination will be held at the Royal Naval College, Greenwich, in the month of May or June of each year. The exact date may be ascertained on application to the Secretary of the Admiralty, on or after the 1st of February.

13. The following will be the subjects of the examination, and the maximum number of marks for each subject—to be modified at any time, if considered desirable:—

I.—*Compulsory Subjects.*

	Marks.
General paper in elementary mathematics and mensuration	400
Statics, hydrostatics, and graphical statics	500
Hydraulics, pneumatics, and dynamics	500
Elementary theory of mechanism and machinery	500
Physics I.—Heat and light	500
Physics II.—Electricity and magnetism	500
Chemistry	500
Heat and combustion	700
Steam and the steam engine..	700
Practical engineering	700
Workshop appliances and practice	600
Mechanical drawing..	500
Total	6600

II.—*Optional Subjects.*

Advanced algebra and trigonometry..	500
Conics and differential and integral calculus	600
Applied mechanics and strength of materials	600
Practical physics	300
Metallurgy	400
Design of machinery details	500
Engineering	500
Total	3400
Grand total	10,000

14. Candidates who obtain less than 30 per cent. of the marks for compulsory subjects will be considered ineligible for appointment. The eligible candidates will be divided into three classes:—First class: Those who obtain at least 60 per cent. in the compulsory and optional subjects combined. Second class: Those who obtain at least 50 per cent. in the compulsory subjects only, but fail to reach the standard of the first class. Third class: Those who obtain at least 30 per cent. in the compulsory subjects only, but fail to reach the standard for a higher class.

15. Successful candidates, up to the number of vacancies requiring to be filled, will be entered in the Royal Navy as probationary assistant-engineers on the 1st of July succeeding the examination, and will join the reserves at such dockyard ports as may be decided. Officers appointed from the first class will, if they so desire, have the privilege of proceeding to the Royal Naval College on the 1st October succeeding the examination, where they will pass through a course of higher instruction along with those who enter from the Training College at Keyham. Officers appointed from the second and third classes will remain in the reserves, to be appointed to H.M. ships as their services are required.

16. Officers who obtain first and second-class certificates will be allowed to count twelve months and six months of their probationary time respectively towards increase of pay from 6s. to 7s. 6d. a day, and towards promotion to engineer.

17. Two assistant-engineers, who take the highest places at the examination of the whole of the assistant engineers at the Royal Naval College, on the completion of their first course at Greenwich, are selected annually to pass through a further course of scientific instruction if they desire it. These two are allowed to study at the college for a second and third session. They receive 7s. 6d. a day, and 1s. 6d. a day towards the mess. On the completion of the third session at the college, they will be sent to sea as assistant-engineers, and, after one year's service at sea—or such other period as may hereafter be fixed—they will be considered eligible to fill

---

* The case of candidates whose age is slightly outside these limits will receive special consideration.

vacancies occurring in the civil appointments at the dockyards and at the Admiralty.

B.—PARAGRAPHS APPLICABLE TO CANDIDATES POSSESSING COLLEGE CERTIFICATES, WHO ARE ENTERED WITHOUT UNDERGOING THE COMPLETE ADMIRALTY EXAMINATION.

18. As regards educational attainments, every candidate must produce the regular college certificate given after attending the day engineering course—either civil, mechanical, or electrical—for not less than one year, or, in the absence of this, must produce a certificate from responsible officers of the college that he has attended one of the above day courses for not less than one year, and passed the examination with credit at the end of that time in the subjects taught. Only such certificates as can be considered by the Admiralty, as regards educational attainments, as equivalent to a third-class Admiralty educational certificate will be accepted.

19. The only examination candidates under these regulations will be required to undergo will be in engineering subjects as described in paragraphs 21 and 22.

20. All applications for the forms to be filled up by candidates must be sent to the Secretary of the Admiralty, London, S.W., and care must be taken that the forms, when filled up, are returned with the certificates of birth, training, and moral character.

21. The engineering examinations will be held at the Admiralty at intervals of about four months. The date of the next examination will be furnished to accepted candidates.

22. The examination will consist of two written papers in practical engineering and workshop appliances and practice, and a *vivâ voce* examination in the same subjects.

23. Successful candidates, up to the number of vacancies requiring to be filled, will be entered in the Royal Navy as probationary assistant-engineers, and will join the reserves at such dockyard ports as may be decided. Officers appointed under these regulations will not proceed to the Royal Naval College for further study, unless they subsequently undergo the examination and attain the standard referred to in paragraphs 12 to 14. They will remain in the reserves, to be appointed to H.M. ships as their services are required.

24. Every officer entered in the Navy under these conditions will be treated as regards pay and promotion in the same manner as officers who have obtained a third-class Admiralty educational certificate, but will be allowed to present himself on one occasion before attaining the rank of engineer—should the exigencies of the service permit—at the complete Admiralty examination—referred to in paragraphs 12 to 14—for the purpose of obtaining a certificate of a higher class.

25. The foregoing regulations will be generally followed, but their Lordships may modify them from time to time as considered desirable.

MEDICAL EXAMINATION.

26. With a view to prevent the inconvenience and expense being incurred of preparing candidates for entry as probationary assistant-engineers in her Majesty's Navy who may be physically unfit for her Majesty's Service, it is suggested that the candidates be examined by the medical adviser of the family, or any other registered medical practitioner, to whom the following points may be submitted as those upon which they will be physically examined by naval medical officers. It is to be understood that this private examination is merely suggested as a guide to candidates, and to lessen the chances of disappointment, and that it is by no means intended to take the place of, or to influence in any way, the regular official physical examination:—A weak constitution, arising from imperfect development or weakness of the physical powers of the body, either hereditary or from chronic disease, wounds, or injuries. Chronic eruptions on the skin or scalp. Malformation of the head, with a dry, harsh, divergent state of the hair of the scalp, fracture or depression of the bones of the skull, disordered intellect, imbecility, epilepsy, paralysis, or impediment of speech. Blindness or defective vision, as tested by Snellen's test types, in one or both eyes, fistula lachrymalis, and ptosis. Impaired hearing, or discharge from one or both ears, disease or thickening of the lining membrane of the external ear. Diseases of the bones of the nose or of its cartilages, or polypus. Disease of the throat, palate, or tonsils; unsound teeth, offensive breath from constitutional causes, unhealthy gums, scrofulous diseases of the glands of the throat or neck, external cicatrices from scrofulous sores. Functional or organic diseases of the heart or blood vessels, deformity or contraction of the chest, flattening of the sub-clavicular regions, phthisis, hæmoptysis, bronchitis, dyspnœa, aphonia, chronic cough, or other symptoms of tubercular exudation into the pulmonary tissues. Swelling or distention of the abdomen, undue obesity, disease or enlargement of the liver, spleen, or kidneys. Rupture, weakness, or distention of the abdominal rings; vesical weakness, or incontinence. The existence of any congenital defect, or of varicocele. Any disease of or pertaining to the alimentary canal. Paralysis, weakness, impaired motion, or contraction of the upper or lower extremities, from whatever cause; aneurism, a varicose state of the veins, especially of the leg. Bunions, distortion, malformation of the feet, or malposition of the finger or toes. Distortion of the spine, of the bones of the chest, or pelvis, from injury or constitutional defect.

By Command of their Lordships,
Admiralty, January 4th, 1896. EVAN MACGREGOR.

NOTE.—Appended to these regulations is a memorandum of the several grades of engineer officers of the Royal Navy, together with the scales of full and half-pay, and other information.

Memorandum as to the Pay, &c., of Engineer Officers of the Royal Navy.

	Full pay.		Half pay.	
	Year of 365 days.	One day.	Year of 365 days.	One day.

Inspectors of machinery	638 15 0	1 15 0	401 10 0	1 2 0
Chief inspectors of machinery	730 0 0	2 0 0	438 0 0	1 4 0

† Junior service allowed to reckon on the following scale:—Under twelve years' service in junior rank, nil; above twelve years' service in junior rank, one-third of the period in excess of twelve years. Junior service is all confirmed time served as assistant-engineer and engineer from the age of twenty. Officers passed over for unsatisfactory conduct or failure to qualify for promotion to the senior grade, but who may subsequently be promoted, are not allowed to count their junior service, between the dates of their being passed over and the dates of their promotion.

Charge pay.—Engineer officers when in charge of the machinery of ships in commission are allowed charge pay varying from 1s. to 9s. a day, the rate for each ship being determined by the Admiralty. Senior engineers of ships in commission, having engines of 3000 indicated horse-power and upwards, are allowed an additional 1s. a day. Engineer officers when in charge of the machinery of torpedo boats in commission are allowed charge pay at rates determined by the Admiralty. Engineers or assistant-engineers when in charge of the machinery of torpedo boats in reserve are allowed charge pay at 1s. a day.

Half charge pay.—In ships in the Fleet and Dockyard Reserves, half of the rates of charge pay, and senior engineers' allowances, payable whilst in commission, are to be paid to their engineer officers, but in the case of ships with engines of 2000 indicated horse-power and under, charge pay at 1s. a day is to be paid.

Extra pay.—The chief inspectors and inspectors of machinery in the reserves, in consideration of their responsible duties, are allowed an additional 3s. a day. Fleet, staff, and chief engineers of flag ships are allowed an additional 2s. 6d. to 5s. per day.

Promotion.—Assistant-engineers, qualified for advancement, are eligible for promotion to the rank of engineer after five years' confirmed service. The promotion of engineers, chief engineers, and inspectors of machinery, depends on the number of vacancies that occur in the several superior ranks

Retired pay.—The following table shows the age for retirement from active service of engineer officers, and the maximum retired pay of each rank:—

Rank at time of retirement.	Age.		Maximum retired pay.
	Optional retirement may be allowed at.	Compulsory retirement.	
Assistant-engineers ..	—	40	£50 a year
Engineers	—	45	£150 a year (qualified for promotion) £130 a year (not qualified for promotion)
		(May be retained to the age of 50)	£187 10s. (qualified for promotion) £162 10s. (not qualified for promotion)
Chief, staff, and fleet engineers	50‡	55	£450 a year
Inspectors of machinery	55	60	£500 a year
Chief inspectors of machinery	55	60	£500 a year

‡ Optional retirement suspended for the present.

On attaining the rank of chief engineer and afterwards, and if forty years of age, or over, the amount of retired pay depends both on age and length of service, the maximum for each rank being as above, and the minimum rate the amount of half pay of the officer as per scale previously given. Retirement would take place between the ages given in the above table except in the following cases:—(1) Five years' half-pay time in either of the ranks of assistant-engineer, engineer, chief, staff, or fleet-engineer, or seven years' half-pay time in the ranks of inspector, or chief inspector of machinery. (2) Physical unfitness for service. (3) Misconduct. Pensions or gratuities for wounds or injuries can be granted by the Admiralty in addition to the ordinary retiring allowances. Retired pay and half-pay are subject to deductions in case of misconduct.

Naval and Greenwich Hospital pensions.—These pensions are established for affording some relief to retired officers, and are awarded to such retired officers as may be, in the opinion of the Admiralty, most deserving, under the conditions published in the Queen's Regulations and Admiralty Instructions.

Pensions to widows.—The widows and children of engineer officers who had completed ten years' commissioned service are eligible, under stipulated conditions, to pensions and compassionate allowances. The rates payable and the regulations governing their award are published in the Queen's Regulations and the Quarterly Navy List.

Relative rank.—Assistant-engineers rank with sub-lieutenants according to date of commission. Engineers of less than six years' seniority rank with but after lieutenants under eight years' seniority. Engineers of six years' seniority rank with lieutenants of less than eight years' seniority according to date of commission. Chief engineers rank with but after lieutenants of eight years' seniority. Staff engineers rank with lieutenants above eight years' seniority. Fleet engineers rank with commanders according to date of commission. Inspectors of machinery, under eight years' service on full pay as such, rank with captains under three years. Inspectors of machinery, of eight years' service on full pay as such, rank with captains of three years. The captain to reckon his seniority from the date of completing three years in that rank. The inspector of machinery to reckon his seniority from the date of completing eight years' service as such. Chief inspectors of machinery rank with captains of three years' seniority according to date of commission.

SYLLABUS OF INSTRUCTION IN PURE AND APPLIED MATHEMATICS, PHYSICS, AND CHEMISTRY.

STATICS.

Definition and specification of a force:—Its measurement by straight lines. Composition of two forces. Analytical expressions for the resultant and the angles it makes with each of its components. Parallel forces. Couples. Equilibrium of a body—(1) under two forces; (2) under three forces. Principle of the lever. Pressure on the fulcrum of the lever. Moment of a force about a point. Resultant of moments of two forces. Conditions of equilibrium of a body acted on by any number of forces in one plane.

Centre of gravity:—Way to find it.—(1) experimentally; (2) by calculation. Centre of gravity of any number of particles. Centres of gravity of (1) a uniform triangle; (2) a circular arc and sector; (3) hemispherical surface and solid; (4) pyramid and cone; (5) of a body with a part removed from it or another body added to it.

Friction:—Laws of friction and the determination of limiting friction between two bodies.

Machines:—(1) Lever. (2) Wheel and axle. (3) Pulley. (4) Systems of pulleys. (5) Inclined plane. (6) Wedge. (7) Screw. The same machines with friction.

Stable, unstable, and neutral equilibrium:—Condition that a body may stand when placed on a table. Conditions for toppling over and for slipping.

Text book recommended:—"Elementary Statics," by J. B. Lock.

HYDROSTATICS.

Definitions of fluid, liquid, gas:—Definition of fluid pressure. Expression for pressure at any point of a heavy liquid. Resultant pressure. Resultant horizontal pressure on any surface immersed in liquid. Vertical resultant pressure on same. Expression for resultant pressure on a plane surface immersed in liquid. Centre of pressure for (1) a parallelogram with one side in surface; (2) a triangle with one side in surface.

Resultant pressure on any body either wholly or partially immersed in liquid.

Conditions of floating:—Stability and metacentre illustrated by simple cases.

Specific gravity:—The hydrostatic balance. Hydrometers. Bramah's press.

Book recommended:—"Besant's Elementary Hydrostatics."

PNEUMATICS.

Boyle's Law, and how it is experimentally tested. Charles's Law.

Syphon. Air pumps. Common pump. Condensing pumps. Barometers. Diving bell.

Book recommended:—"Besant's Elementary Hydrostatics."

ELEMENTARY DYNAMICS.

Motion in a straight line. Uniform velocity. Velocity uniformly accelerated.

Mass. Momentum. Rate of change of momentum. Laws of motion. Weight. Atwood's machine. Motion on inclined plane.

Impact. Elasticity. Oblique impact. Units of measure. C.G.S. system. Composition of velocities and of accelerations. Projectiles.

Uniform motion in a circle. Motion in a circle when not uniform. Simple pendulum. Conical pendulum. Governors.

Work. Energy. Potential and kinetic energies. Principle of the conservation of energy.

Books recommended:—"Lock's Elementary Dynamics." "Garnett's Dynamics." "Worthington's Dynamics of Rotation," Chaps. I.—IV.

HIGHER ALGEBRA (Optional).

Theory of quadratic equations. Permutations and combinations. Binomial theorem. Exponential and logarithmic series. Intermediate coefficients and partial fractions. Simple conditions of convergency. Summation of series of the types.

(1) $\Sigma\, n^2$.
(2) $\Sigma\, n^3$.
(3) $\Sigma\, n\,(n+1)\,.\,.\,.\,(n+r)$
(4) $\Sigma\, \dfrac{1}{n\,(n+1)\,.\,.\,.\,(n+r)}$

Book recommended;—"C. Smith's Higher Algebra."

HIGHER TRIGONOMETRY (Optional).

De Moivre's Theorem. Expansions for sin θ and cos θ. Exponential forms for the same. Hyperbolic functions. Summation of trigonometric series. Factors of binomial expressions, such as $1 + x^n$. Book recommended:—"Lock's Higher Trigonometry."

ANALYTICAL CONICS (Optional).

Rectangular and polar co-ordinates:—Length of a line. Area of a triangle. Equation of a straight line. Condition that two lines may be (1) parallel, (2) perpendicular. Conditions of collinearity of three points. Angle between two lines where equations are given. Length of perpendicular to a line from a point. Polar equation of a straight line. Equation of a circle. Representation of a point on a circle in terms of a single parameter. Equation of tangent to a circle. Chord of contact of tangents from external point. Polar equation of a circle. Geometrical definition of a conic section by means of focus and directrix. Equation of a parabola. Representation of a point on a parabola by means of a single parameter. Equation of the chord joining two points and thence of the tangent. Equation of the normal. Simple focal properties. Form of the curve as plotted out from the equation. Diameters. Equation of an ellipse. Centre of the curve. Representation of a point on an ellipse by a single parameter. Excentric angle. Ellipse regarded as orthogonal projection of a circle. Equation of a chord joining two points on an ellipse and thence the equation of a tangent. Equation of a normal. Simple focal properties. Conjugate diameters. Equation of a hyperbola. Representation of a point on hyperbola in terms of a single parameter. Equations of chord, tangent and normal. Focal properties. Asymptotes. Conjugate hyperbola. Conjugate diameters. Polar equation of conic referred to focus, with polar equation to tangent and chord. Book recommended:—"C. Smith's Elementary Treatise on Conic Sections.'

DIFFERENTIAL AND INTEGRAL CALCULUS (Optional.)

Differentiation of functions of a single variable. Integration of rational algebraical and trigonometrical functions. Simple geometrical applications of differentiation. Tangents and normals in rectangular and polar co-ordinates. Evaluation of areas of plane curves in simple cases. Successive differentiation. Curvature of plane curves. Questions in maxima and minima of functions of one variable. Taylor's and Maclaurin's expansions of functions of a single variable, the convergency of the expansions being assumed. Indeterminate forms. Book recommended:—"Greenhill's Differential and Integral Calculus," Chapters I., II., III., IV., except §§ 29, 30, 63-65, 67, to end of chapter, 80-87, 93-96, 100, 107, 108, 111.

CHEMISTRY.

Classification of the elements:—Hydrogen; its preparation and properties. Oxygen; its preparation and properties. Mechanical mixtures and chemical compounds. Water; physical and chemical properties. Impurities in water. Hardness in water. Rain, spring, and sea water. Nitrogen; its preparation and properties. Nitrous and nitric oxides. Ammonia. Hydric nitrate. Acids, bases, and salts. Composition and impurities of the atmosphere. Chlorine; its preparation and properties. Hydro-chloric acid gas. Bromine. Iodine. Carbon. Carbonic oxide. Carbonic acid; its properties and preparation. Marsh gas and olefiant gas. Coal gas; its manufacture and bye-products. Silicon. Silica. Sulphur; its occurrence in nature and purification. Sulphuretted hydrogen. Sulphurous acid. Sulphuric acid. Book recommended:—"Roscoe's Lessons in Chemistry."

HEAT.

Temperature:—Measurement of temperature. Filling, marking, and graduating thermometers. Different thermometric scales. Maximum and minimum thermometers. Expansion of solids. Linear and cubical expansions. Compensation of pendulums and balance wheels. Expansion of liquids. Peculiarity in the expansion of water. Expansion of gases. Perfect gases. The air thermometer. Absolute zero of temperature. Quantity of heat. Thermal unit. Calorimeters. Specific heat and methods of determining it for solids and liquids. Latent heat. Laws of fusion and solidification. Freezing mixtures. Cold produced by evaporation. Boiling point of liquids. Latent heat of vaporisation. Pressure of vapours. Saturated and superheated vapours. Determination of pressure of saturated steam at different temperatures. The dew point. Hygrometers. Convection of heat in liquids and gases. Heating by water pipes. Draught of chimneys, &c. Conduction of heat. Safety lamp. The radiation, absorption, and reflection of heat. Theory of exchanges. Laws of cooling. The mechanical equivalent of heat. Joule's experiments. Specific heats of a gas at constant pressure and at constant volume. Books recommended:—"Deschanel's Natural Philosophy —Heat." "Larden's Heat" (latest edition).

LIGHT.

The emission of light:—Luminous gas flame. Bunsen-burner. Lime light. Electric light. Shadows. Umbra and Penumbra. Laws of intensity of light. Photometers. Velocity of light as determined by the motions of Jupiter's Satellites. Reflection of light. Formation of images by plane and concave mirrors. Focal properties of concave parabolic and spherical mirrors. Refraction of light. Law of sines. Determination of coefficient of refraction. Refraction through a prism. Lenses. Formation of images by a convex lens. Chromatic dispersion of light. The solar spectrum. Book recommended:—"Deschanel's Natural Philosophy."

MAGNETISM.

The elementary properties of a magnet:—Magnetic induction. Lines of force. Law of force between two poles. Methods of magnetising iron and steel. Definitions of Pole strength, magnetic moment, intensity of magnetisation susceptibility, permeability, saturation. Use of iron pole-pieces and masses of iron in controlling the distribution of lines of force. Comparison of magnetic forces by the method of oscillations.

Terrestrial magnetism:—Dip. Declination. Magnetic charts. Magnetism of iron ships. Different kinds of errors in the compasses of iron ships, and their corrections.

Book recommended:—"Electricity and Magnetism," by Sylvanus Thompson.

Frictional Electricity.

Production of electricity by friction:—Electricity of two kinds. Laws of attraction and repulsion between electrical charges. Coulomb's balance. Lines of force and equipotential surfaces. The electroscope. Conduction of electricity. Inductive effects. The electrophorus. Frictional machines. Pointed conductors. Lightning conductors. Electric condensers. Capacity. Specific inductive capacity. Leyden jars. Inductive machines. Book recommended: — "Electricity and Magnetism," by Sylvanus Thompson.

Voltaic Electricity.

Chemical mode of producing currents:—Electromotive series. Polarisation. Voltaic cells in common use. Standard cells.

Chemical effects of currents:—Voltameters. Storage cells. Electro-plating.

Oersted's experiments:—Electro-magnetic measure of a current. Electro-magnets. Tangent galvanometers. Galvanometer constant. Astatic and reflecting galvanometers. Voltmeter. Ammeter. Ohm's law. Resistance of wires and columns of liquids. Internal and external resistances. Meaning of "series" and "parallel" arrangements. Method of comparing resistances. Rheostat. Wheatstone's bridge. Post-office bridge. Telegraph. Heating effects of a current. Joule's law. Incandescent and arc lamps. Forces between wires carrying electric currents. Solenoids. Electrodynamometers. Laws of induced currents. Ruhmkorff's coil. Telephones. Production of current by rotation of a coil in a magnetic field. The C.G.S. system of units. Practical units. Thermo-electricity. The thermo-pile.

Books recommended:—"Electricity and Magnetism," by Sylvanus Thompson; and Ayrton's "Practical Electricity."

Practical Physics (Optional).

In the case of engineer students, a voluntary course will be arranged by the head master according to the circumstances and progress of each student. Marks will be given on the work done during the year. Candidates for direct entry will be examined at the Royal Naval College, Greenwich, on the work they have previously performed in the laboratory, of the character of which they should give notice to the Director of Studies on the first day of their examination.

SYLLABUS OF INSTRUCTION IN APPLIED MECHANICS AND MECHANISM.

Elementary Descriptive Mechanism:—Toothed wheels. Belts and pulleys. Crank and connecting rod. Excentrics. Escapements. Cams. Quick return motions. Linkwork mechanisms. Parallel motions. Ratchets. Feed motions. Trains of wheels. Book recommended:—"Goodeve's Mechanism," Chaps. 1—4, 6.

Mechanism and Machines.

Motion:—Sliding, turning and screw pairs. Relative motion of pairs. Units of velocity. Screw-cutting.

Efforts and resistances:—Sources of efforts and resistances. Elastic fluids. Springs. Gravitation. Graphical representation of efforts and resistances.

Friction:—Coefficients of friction. Ordinary laws of friction. Morin's experiments.

Work and energy:—Unit of work. Principle of work. Conservation of energy. Work in turning. Graphical representation of work. Power.

Oblique and variable forces:—Curve of resistance. Indicator diagrams.

Simple machines:—Definition of a machine. Inclined plane. Wheel and axle. Screw.

Pulleys. Belts and wheel gears.

Simple machines with friction:—Waste work. Efficiency. Inclined planes. Windlass. Screw. Pulleys.

The direct acting engine:—Curve of piston velocity. Effect of obliquity of connecting rod. Motion of slide valve. Angular velocity of connecting rod. Application of the principle of work. Polar and linear curves of crank effort.

Unbalanced forces:—Kinetic energy. Radius of gyration. Storage of energy. Case of an unconstrained body. Potential energy.

Dynamometers:

Strength of Materials: Stress. Strain. Elasticity. Thin cylindrical shells.

Hydraulics.

Head. Velocity due to a given head. Discharge from an orifice.

Hydraulic resistances. Surface friction. Virtual slope of pipes. Discharge through pipes.

Hydraulic machines.

Pneumatics:—Flow of gases under a small difference of pressure.

Statics of Structures (To be included in the examination under Statics.)

Struts and ties. Pin joints. Simple triangular frames loaded at the joints. Triangular trusses. Cranes. Diagrams of forces. Straining actions at any point of a loaded beam. Beams under a single load, or a uniformly distributed load. Diagrams of shearing force, and bending moment in elementary cases.

Book recommended:—Cotterill and Slade's "Lessons in Applied Mechanics," omitting Chapters XVI. to XXI. inclusive.

Graphical Statics (Optional).

Graphical construction of the resultant of any system of forces in one plane. Funicular polygon. Suspension chains. Centres of gravity. Graphical construction of moments. Loaded beams. Book recommended.—"Gray and Lowson's," Chaps V. to X., and XV.

Applied Mechanics and Strength of Materials (Optional).

More advanced questions on the subjects mentioned under "Statics of Structures," "Hydraulics," and "Mechanism and Machines." In addition to these the following subjects:—Epicyclic trains of wheels.

Machines:—Periodic motion. Fluctuation of energy. Fluctuation of speed. Fly wheels. Friction of bearings and screws. Efficiency of mechanism. Two crank engine. Necessary correction of indicator diagrams, due to the inertia of the reciprocating parts of an engine. Brakes. Governors.

Framework girders of the Warren and N-types.

Bending of beams:—Bending of a beam of I-section. Bending in a circular arc. Distribution of stress on the transverse section. Neutral axis. Equations of bending. Moments of inertia. Beams of I-section, approximate methods.

Shearing and torsion:—Rivets. Pin joints. Efficiency of a joint. Normal and tangential stresses. Distortion. Torsion of tubes. Solid and hollow shafts. Power transmitted by a shaft.

Experimental results:—Elastic state. Proof stress. Testing machines. Curves of stress and strain. Plastic state of solids. Effect of impact. Crushing of struts. Gordon's formula. Rigid materials. Fibrous materials. Factors of safety.

Hydraulics as above.

Pneumatics.

Books recommended: — Cotterill and Slade's "Lessons in Applied Mechanics," pp. 127, 128; 220-237; 246-254; 259-329; 347-512. Gray and Lowson's, Chap. V. to X., XV. "Goodeve's Mechanism." Chaps. I. and II., omitting Arts. 53-57 inclusive. and Art. 90. Chap. III., omitting Arts. 94-104 inclusive, Art. 111, Arts. 118-123 inclusive. Chap. IV., omitting Arts. 136, 137, 138. Chap. VI., omitting Arts. 169, 170, 175, 176. All the examples are to be worked.

SYLLABUS OF ENGINEERING SUBJECTS, COMPRISED IN THE EXAMINATIONS FOR APPOINTMENTS AS ENGINEER OFFICERS IN THE ROYAL NAVY.

This syllabus is intended to be a guide to candidates in preparing for the above examinations; but, although it practically covers all the subjects on which questions will be set, it must be clearly understood that questions may be set on points not specifically mentioned.

Heat and Combustion.

The paper on these subjects will include questions on:—(1) Elementary notions on the dynamical theory of heat, elementary relations between heat and mechanical energy, with special reference to the steam engine. (2) Fuels, and the combustion of fuel in marine boiler and other furnaces.

The chief points included are:—

Heat.—Nature of heat. General effects. Scales of temperature. Absolute temperature. Laws of thermodynamics. Conversion of heat into work and *vice versâ.*

Conditions and value of maximum efficiency in perfect heat engines.

Communication of heat:—Radiation: Laws, clothing of boilers, &c. Conduction: Internal and external. Rate of conduction through plates. Convection: Circulation of water in boilers.

Application of heat to water:—Sensible heat. Latent heat. Boiling point. Influence of pressure and density on boiling point. Connection between temperature pressure and volume of steam. Formulæ for latent heat and total heat of evaporation.

Density of steam:—Specific volume. Relative volume. Rules for determining the specific volume of steam, wet or dry.

Properties of saturated, moist, and superheated steam.

External and internal work during evaporation.

Action of steam in non-expansive engines, and in expansive engines—assuming the expansion hyperbolic. Heat expended. Work done. Heat rejected, &c. Mean pressure. Graphic representations.

Elementary notions of the general effect of clearance, wire drawing, compression, and the action of the cylinder walls on the efficiency of the steam.

Expansion of steam in stages. Effect on economy.

Real and apparent ratios of expansion.

Superheating.

Steam jackets.

Elementary problems.

Books recommended:—Cotterill's "Steam Engine," pp. 1-70; Sennett's "Marine Steam Engine," Chaps. II.-IV.; IX.-XI.

Combustion.—Properties, approximate composition and uses of the different kinds of fuel.

Nature of combustion. Changes during combustion of coal and other fuels in ordinary furnaces. Amount of air chemically and practically necessary for combustion. Rate of combustion in furnaces of marine boilers. Use of combustion chambers.

Calorific values. Heat of combustion. Temperature of combustion. Evaporative power of fuels. Formulæ.

Causes of loss of evaporative power. Methods of dealing with these losses.

Prevention of smoke. Stoking.

Draught:—Natural draught. Draught of a funnel in inches of water.

Steam blast and other methods of forcing draught. Advantages and disadvantages.

Forced draught with closed stokeholds.

Heating surface:—Efficiency of heating surfaces.

Causes and prevention of spontaneous combustion.

Elementary problems.

Books recommended:— Sennett's "Marine Steam Engine," Chaps. V. and VI.; Rankine's "Steam Engine," pp. 267-297—6th edition.

Steam and the Steam Engine.

Under this heading will be included:—A brief history of the development of the steam engine, with special reference to the chief types of engines and boilers that have been in use for purposes of marine propulsion.

Action of the steam in the steam engine.

Practical application of the principles involved in the subjects mentioned under "Heat and Combustion."

Indicators, construction and use. Theoretical and actual indicator diagrams from the different types of engines. Calculation of indicated horse-power from the indicator diagram. Effects of faults in the engines on indicator diagrams. How to remedy these faults. Method of combining indicator diagrams.

Estimation of the consumption of steam from the indicator diagrams.

Condensation of steam.—Amount of condensation water required.

Expansion by linking up. Independent linking up of two or more cylinders. Variation of power from cylinders by linking up. Throttling. Action of expansion valves.

Stage expansion engines: practical advantages and disadvantages.

Gauges and other measuring instruments:—Pressure and vacuum gauges, counters, anemometers, dynamometers, &c.

Ventilation of boiler and engine-rooms. Increase of power by using forced draught.

Consumption of fuel. Economical speeds.

Rudimentary principles of propulsion. Simple problems.

Tests of machinery and boilers, &c., to ascertain their fitness for service. Methods of conducting trials of machinery and boilers.

Experiments on steam engines, boilers, &c.

Book recommended:—Sennett's "Marine Steam Engine."

[Note.—Detail of construction in the descriptive part of this paper will not be required, except on a few points, such as measuring instruments, &c. It is intended rather to form an examination in the general methods of applying theoretical principles and matters of experience to ordinary practice.]

Practical Engineering.

These papers will be set as an examination in the construction and management of the different types of steam machinery and boilers used for marine purposes, both propelling and auxiliary.

The auxiliary machinery will include steering engines and gear, distilling machinery, circulating, starting, turning, fan, feed, &c., engines, with pipes and valves in connection.

Some knowledge of the machinery for special purposes will also be required, such as torpedo boat machinery, electric light and air-compressing machinery, capstan and hydraulic pumping engines, &c.

Questions may also be set on the chief types of machinery for certain shore purposes, such as cranes and other lifting and hauling apparatus, pumps, &c.

The other points that will be included in these papers are, principally:—Corrosion and preservation of boilers, &c.

Priming: causes, effects, and means of prevention.

Hydrometers: density of water in boilers. Problems.

Distilling apparatus: double distillers. Evaporators.

Fittings and arrangements for forced draught. Experience with forced draught.

Pumping, water-tight, fire, and communicating—telegraph and voice pipes, &c.—arrangements on board ship.

Lubricants and lubricating arrangements.

Elementary knowledge of practical iron and steel shipbuilding.

Procedure in fitting engines on board a vessel.

Necessary examination of machinery and boilers, &c., after being at work some time.

Wear and adjustment of various parts of the engines.

Repairs that can be undertaken afloat.

Objects of fitting separate feed pumps.

Expansion joints: use of, attention they require.

Cause, effect, and prevention of galvanic action due to use of various metals in the hull and machinery of ships, &c.

Raising steam, starting and stopping, precautions to be observed.

Points to be attended to in watch keeping. Hot bearings. Causes of low vacuum.

Racing. Objects and disadvantages of governors.

Details of screw propellers and paddle-wheels, &c. &c.

Illustrative sketches, where necessary, should accompany th answers.

Book recommended:—Sennett's "Marine Steam Engine."

Workshop Appliances and Practice.

The examination in this subject is intended to cover the following:—Descriptions, sketches and modes of working the various machines and machine and hand tools used in the construction of steam machinery and boilers, including the wear and the adjustments required.

Speeds for cutting various materials.

Nature of steel for and method of tempering and hardening tools.

Manufacture of certain special tools and appliances, *e.g.*, surface plates, &c.

The principal processes employed in turning, fitting and erecting machinery, in smiths' and coppersmiths' work, in boiler making, pattern making, and in the iron and brass foundries, with descriptions and sketches of the principal apparatus used.

Processes of galvanising, tinning, soldering, and brazing.

Temporary and permanent repairs in the workshop.

Book recommended:—Shelley's "Workshop Appliances."

Mechanical Drawing.

A paper will be set in this subject comprising:—The construction and use of scales.

Delineation of plane curves, such as the ellipse, parabola, hyperbola, spirals, &c.—Principles and practice of projection.—Conventional shading and colouring.

Construction of simple loci, both from geometrical and mechanical data, such as the practical setting out of curves described by particular parts of machines or linkwork.

Construction of curves from observed or tabular data involving the geometrical use of abscissa and ordinate.

Construction of a curve of areas.

Forms of teeth of ordinary spur and bevel wheels. Meaning of the terms—Pitch, pitch line, root, point, addenda, face, flank, &c.

Sketches of wheel and other gearing.

Sketches and working drawings of details of boilers, machinery, machine tools, &c.

At the examination, candidates will be supplied with rough dimensioned incomplete sketches of machinery details, and they will be expected to produce a complete drawing—two or more views projected one from the other—in pencil to a given scale, with separate drawings of details, if necessary.

Each candidate must also send in for examination rough sketches of some piece of machinery with a finished scale drawing made from them.

In the case of an engineer student at the training school, it must be certified by the chief engineer of the dockyard that, to the best of his belief, these are the work of the student unassisted.

In the case of a candidate for direct appointment, a certificate to this effect must be given by the professor of his college, or by a member of the firm at which he received his practical training.

In every case the candidate must sign a declaration that he has made the drawings and sketches himself without any assistance.

It is necessary that the rough sketches should accompany the finished drawings, as no marks can be given for drawings that are simply copies of others.

Candidates for direct appointments must give in their specimen drawings and certificates to the officer conducting the written examination in "Mechanical Drawing" at the time of that examination.

Engineering (Optional).

In this paper more advanced questions will be set on the subjects of all the preceding subjects.

Design of Machinery Details (Optional).

In this subject, although a general knowledge of the principles of design is expected, difficult mathematical investigations will not be required.

The chief points on which the examination will be based are—Experimental strength of materials used in machine construction; physical and mechanical properties; the straining actions to which the different parts of machinery are subject, and the influence of these actions in determining their dimensions; stress; strain; ultimate strength, limit of elasticity; factor of safety, &c.; simple problems.

Other considerations affecting design. Choice of materials.

Amount of steam space, and grate and heating surfaces allowed in boilers, and cooling surface in condensers.

The ordinary kinds of screw fastenings, proportions of bolts and nuts.

Design of the following:—Single, double, and treble lap and butt riveted joints for various uses—socket joints, knuckle joints, keys.

Detail design of piston-rod, propeller shaft, and flange coupling.

Dimensions of cylinder and slide valve ports.—Zeuner's diagram.

Thickness of boiler shells and furnaces. Diameter and pitch of stays.

Diameter of safety valves. Compression of safety valve springs, &c.

Tests of materials usually made to ensure their fitness for constructive purposes. Effects of heat on strength, &c., of steel, iron, copper, and gun-metal.

Metallurgy (Optional).

Characteristic physical properties of the useful metals:—Tenacity. Ductility. Elasticity. Plasticity. Conductive power, &c.

Iron.—Occurrence in nature. Principal methods of extracting iron from its ores.

Extraction as cast iron:—Calcination. Smelting. Blast furnace and fittings. Hot and cold blast. Fluxes, &c. Chemical action in blast furnaces.

Cast iron. -Manner in which carbon is associated. Varieties of cast iron. Chill casting. Remelting of cast iron. Foundry cupola.

Wrought iron.—Chemical and other distinctions from cast iron.

Manufacture from cast iron:—Refining. Puddling. Reverberatory furnace. Removal of slag. Rolling mills. Piling, &c.

Steel.—Mechanical and physical properties. Chemical and other features distinguishing it from cast iron and wrought iron. Conversion of wrought iron into steel. Cementation. Blister steel. Conversion of blister steel into shear steel and into cast steel. Properties and uses of shear and cast steel. Production of Bessemer steel. Description of converter and process. Siemens-Martin steel. Open hearth process. Steel castings. Annealing. Hardening and tempering steel. Blue heat. Precautions to be observed in working steel plates. Case hardening. Malleable cast iron. Properties, strength, and uses of iron and steel. Fractures of various qualities of iron and steel. Inferences. Cold shortness. Red shortness. Burnt iron.

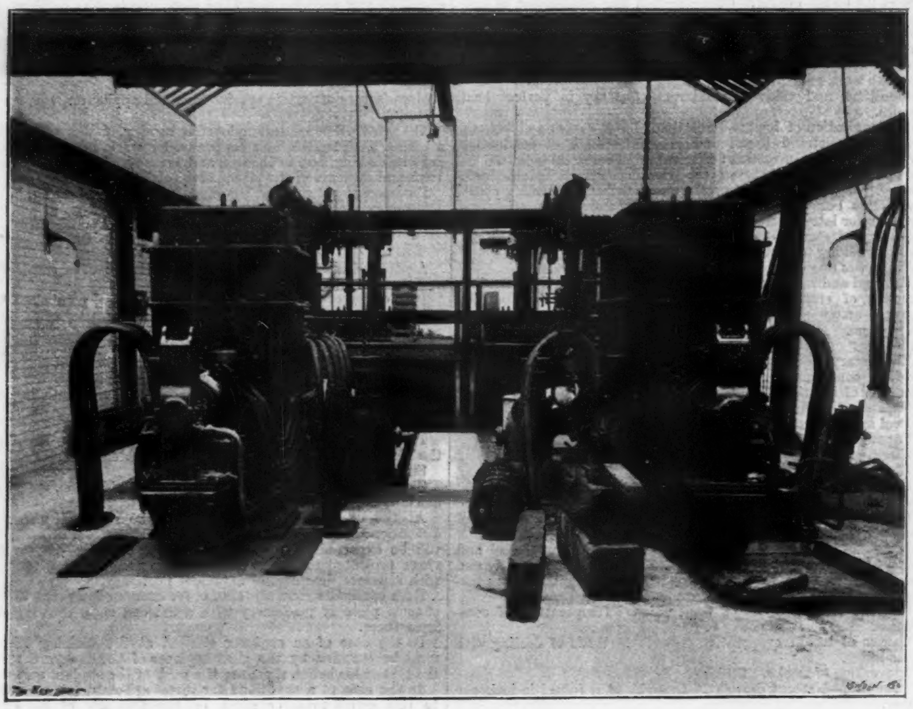
Copper.—Occurrence in nature. Extraction from its ores by Welsh process. Removing iron, and other foreign substances. Blister copper. Refining, &c. Effects of foreign substances on the quality of copper. Strength of copper. Properties and uses of copper.—Properties and uses of tin, zinc, and lead.

Composition and uses of the following alloys:—Gun-metal and brass for various purposes. Naval brass. Muntz metal. Delta metal. Phosphor bronze. Solder and spelter. White metal for bearings. Experimental testing of metals.

It must be borne in mind that some of these subjects are closely related to each other, so that questions may be set in any paper partly bearing on the subjects mentioned under another heading.

THE ELECTRO-CHEMICAL COMPANY'S WORKS AT ST. HELENS.

IT had been known for several years that by the agency of an electric current common salt could be resolved into caustic soda and chlorine gas. Until recently, however, experiments in this direction had been mainly confined to the laboratory, and had failed to obtain commercial results. It was not until the processes patented by Colonel Holland and Mr. James Richardson were invented that endeavour was successfully made to utilise this knowledge commercially. Works on a small scale were established by a syndicate at Snodland, Kent, where during two years the systems were practically tested. The results there obtained justified an extension of the undertaking, and the Electro-Chemical Company was formed.

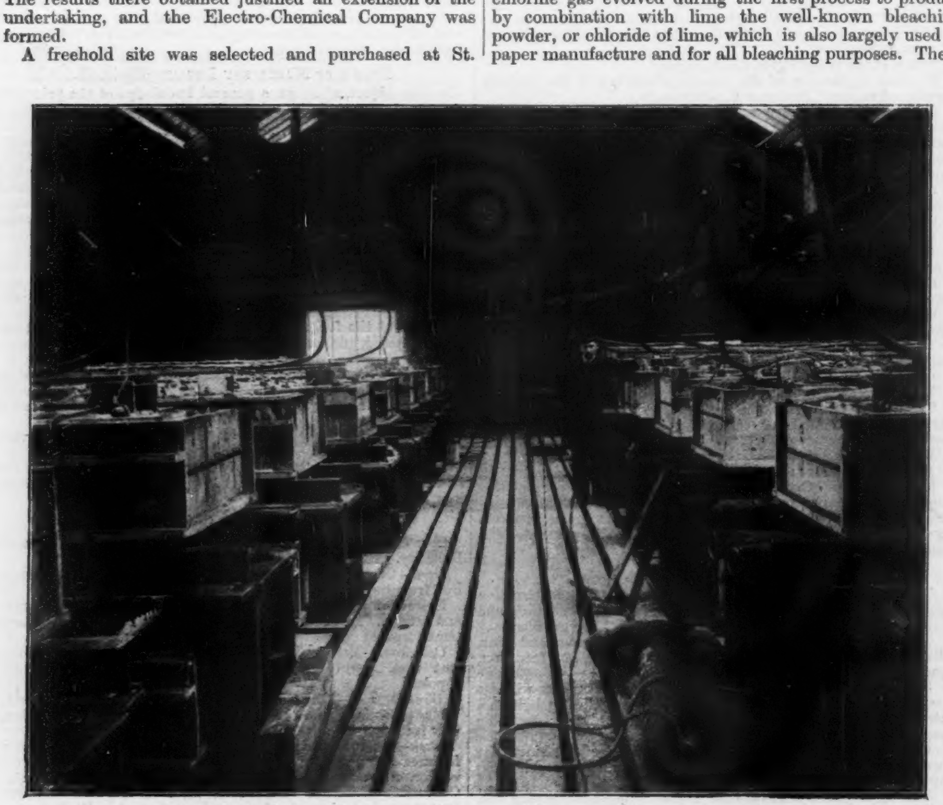


THE DYNAMO ROOM

A freehold site was selected and purchased at St. Helens, Lancashire, the centre of the chemical manufacturing industry. The area of this site is fifteen acres. It has a frontage of about 300 yards closely abutting on the mineral line of the London and North-Western Railway, from which two sidings afford ingress and egress to and from the company's works, throughout which rails are laid for locomotive use. A branch of the same railway bounds the site on one side, while on the other flows the St. Helens and Mersey Canal. On this the company has a wharf provided with a steam crane. Upon this site there have already been erected extensive buildings, large additions to these being now in progress.

The selection of the locality for the works was greatly determined by the proximity to coal pits. Dr. John Hopkinson, F.R.S., Past-president of the Institution of Electrical Engineers, when reporting to the syndicate, had based his calculation as to the commercial efficiency of the process upon a coal supply being obtained at eight shillings per ton, but all the fuel used at the works is now delivered at four shillings per ton.

Before describing the system of manufacture followed, it may be stated that its objects are by electrolysis to obtain with unprecedented economy, first, from common salt—chloride of sodium—the caustic soda of commerce. This is very extensively used in paper, soap, oil refining, bleaching, and numerous other manufactures and processes. A second object is the utilisation of the chlorine gas evolved during the first process to produce by combination with lime the well-known bleaching powder, or chloride of lime, which is also largely used in paper manufacture and for all bleaching purposes. There is, further, a third use to which the process can be applied, though as yet it has only been experimentally tried, this being the production of the chlorate of potash so largely used in the manufacture of explosives generally.



THE TANK HOUSE

The basis of the whole system is rock salt, which is obtained by railway direct from Cheshire at a rate for carriage of 2s. 6d. per ton; this low rate being common to all raw materials for chemical manufactures in and around the St. Helens district. The raw salt is treated in an agitator, being dissolved therein into brine of full saturation. After remaining for a time in settling tanks this brine is pumped up to the tank house.

The arrangement of the tanks in this building is a special feature. The present installation of these numbers two hundred, each tank being 20ft. long and 3ft. wide. The material used for them is slate, and they will contain in all 72,000 gallons of brine, a quantity which will yield under the process 100 tons of bleach and 60 tons of 70 per cent. caustic soda weekly. The tanks are grouped in ten sets of twenty tanks each carried upon iron girders. To these three intersecting platforms at different levels give ready access. Each tank is divided into thirty-two cells, these being provided in alternation with suspended anodes and suspended cathodes.

It may here be remarked that difficulties experienced as to the rapid wasting of the charcoal electrode points used as anodes in the earlier stages of trial, threatened to render nugatory the efforts made at Snodland to obtain commercial success. At length the alternative of using pieces of gas-rètort carbon was hit upon, and proved to be very efficient. A description of these novel anodes will be found later on; but it may be stated here that their life is found to be as extended as eight months. The cathodes are mainly cast iron grids, but other forms for these are now undergoing trial with satisfactory results.

The electric current is conducted to the tanks by copper cables laid along and above the centre of each. A strand is unwound from the cable at each cell, the diameter of it thus progressively diminishing. It is understood that this novel and very simple yet effective arrangement is a special patent owned by the Electro-Chemical Company. Each tank requires from four to five volts to send the 700 ampères through it necessary to the process. When the brine in the cells is subjected to the action of a current of the above strength decomposition immediately commences. From the anodes—which are suspended in cells closed at the top but open towards the bottom to permit the inflow of the brine—is given off the chlorine gas. This is drawn off as it forms through lead pipes, which convey it to an earthenware main, the flow being induced by an exhaust fan driven by a separate engine. The liquid caustic soda, which is attracted to the cathodes, passes through iron pipes on its way towards the evaporating room, the hydrogen gas given off at the cathodes escaping innocuously into the air. By an ingenious method which forms part of the patent, the strength of the brine as it weakens under these withdrawals is maintained by feeding common salt into the cathode cells, for doing which suitable so-called "pockets" are provided to each such cell. The strong caustic solution, being heavy, has a tendency to stratify at the bottom of the cathode cells. When this is deemed to be of sufficient strength it is drawn off, and any salt remaining undecomposed in it is separated before being treated finally by evaporation.

We may now follow distinctively the ultimate dealing with the two products thus obtained. The liquid caustic soda has been above described as having been started on its way to the evaporating room. This is provided with large cast iron evaporating pans, there being twelve of these in present use. In them the caustic liquor is evaporated until eight tons of it yield a residuum of one ton of crystal caustic soda, this part of the process occupying from four to five days. The product is then packed into iron drums containing 6 cwt. each, the selling rate of this quantity being 45s. at the present time.

The chlorine gas produced at the anodes has been named as having been exhausted into an earthenware main. Through this it passes into four absorbing chambers, each of about 12,000 cubic feet capacity. Lime of the best quality—obtained from Buxton by rail at a freight rate of 2s. 9d. per ton—is treated adjacent to these chambers and reduced to the finest powder. In this condition it is spread upon the floors of the chambers to a depth of from 5in. to 6in., the deposit being furrowed by coarsely toothed wooden rakes. The gas, being heavy, falls upon the lime and is rapidly absorbed, the admixture producing chloride of lime or bleaching powder of full commercial strength. This is removed through hoppers in the floors of the chambers, and is packed in wooden casks of a capacity of from 6 cwt. to 7 cwt. The present selling price of the bleaching powder is about £7 5s. the ton.
